Let H be a Krull monoid with finite class group G, and let $u \in H$ be an atom (an irreducible element). The local tame degree $\mathsf{t}(H,u)$ is the smallest integer $N \in \mathbb{N}_0$ with the following property: for any multiple a of u and any factorization $a = v_1 \cdot \ldots \cdot v_n$ of a into atoms, there is a subproduct which is a multiple of u, say $v_1 \cdot \ldots \cdot v_m$, and a refactorization of this subproduct which contains u, say $v_1 \cdot \ldots \cdot v_m = u u_2 \cdot \ldots \cdot u_\ell$, such that $\max\{\ell, m\} \le N$.

The local tame degree $\mathsf{t}(H,u)$ measures the distance between an arbitrary factorization of a and a factorization of a which contains u. So u is a prime element iff $\mathsf{t}(H,u) = 0$. The (global) tame degree $\mathsf{t}(H)$ is the supremum of the local tame degrees over all atoms $u \in H$. The finiteness of the class group easily implies that the finiteness of the tame degree.

We discuss upper and lower bounds for $\mathsf{t}(H)$, and the relationship between $\mathsf{t}(H)$ and the tame degree $\mathsf{t}\big(\mathcal{B}(G)\big)$, where $\mathcal{B}(G)$ is the monoid of zero-sum sequences over the class group G.
