John R Burke* (jrburke@wesleyan.edu), Department of Mathematics and Computer Science,
265 Church Street, Middletown, CT 06457. *The significances of links in knot
concordance*. Preliminary report.

In the talk, we will define the concordance group of knots and discuss the n -solvable filtration of this group defined by Cochran, Orr, and Teichner. We will then discuss some of the previous results about the structure of the concordance group, in particular, the structure of the abelian quotient groups, G_n , of n -solvable knots modulo n : 5-solvable knots. We will end by discussing how by using genetic infection with string links and not knots alone one can construct knots in G_n which are linearly independent from previously studied knots.
