## THE SPACES $L^{p}$ WITH $0<p<1^{1}$

MAHLON M. DAY ${ }^{2}$

If we have a Lebesgue measurable set $E$ in any $n$-dimensional euclidean space, and have any positive number $q$, we define $L^{q}(E)$ to be the class of all real-valued Lebesgue measurable functions $f$ on $E$ for which $\int_{E}|f|^{q}<\infty$. As is well known, whenever $q \geqq 1$ the class of functions $L^{q}(E)$ is a Banach space with the norm $\|f\|_{q}=\left(\int_{E}|f|^{q}\right)^{1 / q}$. When $0<p<1$, the function $\|f\|_{p}$ no longer satisfies the triangle inequality $\left\|f_{1}+f_{2}\right\|_{p} \leqq\left\|f_{1}\right\|_{p}+\left\|f_{2}\right\|_{p}$ but in general only the weaker condition $\left\|f_{1}+f_{2}\right\|_{p} \leqq 2^{\nu}\left[\left\|f_{1}\right\|_{p}+\left\|f_{2}\right\|_{p}\right]$, where $\nu=(1-p) / p$. (This can be shown by considering the function $\left(1+x^{p}\right) /(1+x)^{p}$.) If we consider such an $L^{p}$ space as a linear topological space in which the neighborhoods of a point $f_{0}$ are the spheres of radius $\epsilon>0, E_{f} \varepsilon L^{p}\left[\left\|f-f_{0}\right\|_{p}<\epsilon\right]$, it follows from theorems of Hyers and Wehausen ${ }^{3}$ that this topology can be given by an equivalent Fréchet metric. This suggests that while many theorems on Banach spaces which can be applied to the spaces $L^{p}(E)$ with $p \geqq 1$ may fail to hold in those spaces with $0<p<1$, there may still remain many theorems on Fréchet spaces and pseudonormed spaces which may be applicable. However, Theorem 1 shows that almost no results depending on the use of linear (that is, additive and continuous) functionals can be usefully applied in these spaces.

Theorem 1. Any linear functional on $L^{p}(E)$ is identically zero.
The proof of this and of some additional results is given in a series of lemmas using a more general set of assumptions. We assume as a background some knowledge of the first chapter of Saks ${ }^{4}$ book, in which he deals with what he calls "the integral," a completely additive integral having many of the properties of the Lebesgue integral. We consider a set $Y$ of elements $y$, an additive family ${ }^{5} \mathfrak{X}$ of subsets of $Y$ and an additive, non-negative ${ }^{6}$ set-function $\mu$ on $\mathfrak{X}$ such that $\mu(Y)<\infty$. This last condition will be imposed from here until we

[^0]reach Theorem 4. We shall finally remove it altogether and get the same type of theorem giving the linear functionals on any $L_{\mu}^{p}(Y)$. We shall also find the conjugate space of the sequence spaces related to these. For each $p>0$ let $L^{p}=L_{\mu}^{p}(Y)$ be the class of real-valued, $\mathfrak{X}$-measurable ${ }^{7}$ functions $f$ on $Y$ such that $\|f\|_{p}=\left(\int_{Y}|f|^{p} d \mu\right)^{1 / p}<\infty$. It is clear, as in the spaces with $p \geqq 1$, that if $U$ is a linear functional on $L^{p}$, there is a $K \geqq 0$ such that $|U(f)| \leqq K$ whenever $\|f\|_{p} \leqq 1$. We let $\|U\|$ be the smallest such $K$; that is, $\|U\|=\sup _{f}|U(f)|$ where the sup is taken over those $f$ with $\|f\|_{p}=1$. Similarly if an additive functional is bounded on the unit sphere it is easily seen to be continuous and hence linear.

In the series of lemmas immediately following we shall consider a fixed number $p$ with $0<p<1$ and a fixed family $\mathfrak{X}$ and measure $\mu$.

Lemma 1. If $f_{i}, f \varepsilon L^{1}$ and $\left\|f_{i}-f\right\|_{1} \rightarrow 0$, then $\left\|f_{i}-f\right\|_{p} \rightarrow 0$.
Proof. Let $E_{i}=E_{y \varepsilon} Y\left[\left|f_{i}(y)-f(y)\right|>1\right]$, and let $g_{i}(y)=f(y)$ in $E_{i}$, $g_{i}(y)=f_{i}(y)$ in $Y-E_{i}$. Then

$$
\int_{Y}\left|f_{i}-f\right|^{p} d \mu=\int_{E_{i}}\left|f_{i}-f\right|^{p} d \mu+\int_{Y}\left|g_{i}-f\right|^{p} d \mu
$$

We have $\int_{E_{i}}\left|f_{i}-f\right|^{p} \leqq \int_{E_{i}}\left|f_{i}-f\right| d \mu \leqq \int_{Y}\left|f_{i}-f\right| d \mu$; this integral tends to zero by hypothesis. Also $\left\|g_{i}-f\right\|_{1} \rightarrow 0$, so $g_{i}$ converges in measure to $f$; moreover, $\left|g_{i}(y)-f(y)\right| \leqq 1$ for all $y \varepsilon Y$, so, by the Lebesgue convergence theorem, $\int_{Y}\left|g_{i}-f\right|^{p} d \mu \rightarrow 0$.

Lemma 2. Every linear functional on $L^{1}$ can be expressed in the form $U(f)=\int_{\mathrm{Y}} f u d \mu$ where $u$ depends on $U$, is $\mathfrak{X}$-measurable and, except possibly on a set of $\mu$-measure zero, is bounded.

The proof follows that given in Banach ${ }^{8}$ for the special case $Y=(0,1)$. If we let $f_{E}$ be the characteristic function of $E \varepsilon \mathfrak{X}$ and let $\Phi(E)=U\left(f_{E}\right)$, the set-function $\Phi$ thus defined on $\mathfrak{X}$ is additive, $|\Phi(E)| \leqq\|U\| \mu(E)$ and $U(f)=\int_{Y} f d \Phi$ for each $f \varepsilon L^{1}$. By the theorem of Radon and Nikodym (Saks, p. 36) there is an $\mathfrak{X}$-measurable function $u$ such that $\Phi(E)=\int_{E} u d \mu$ and $\|U\|=\operatorname{ess}_{\sup _{y \varepsilon} Y}|u(y)|$. By a theorem on change of measure (Saks, p. 37) we have $U(f)=\int_{Y} f u d \mu$.

Lemma 3. If $U$ is linear on $L^{p}$, there is an $\mathfrak{X}$-measurable, essentially bounded function $u$ on $Y$ such that whenever $f \varepsilon L^{1}, U(f)=\int_{Y} f u d \mu$, while if $f \boldsymbol{\varepsilon} L^{p}-L^{1}$ there exists a sequence $\left\{f_{i}\right\}$ of functions in $L^{1}$ such that

[^1]$\left\|f_{i}-f\right\|_{p} \rightarrow 0$, and for every such sequence $U(f)=\lim _{i \rightarrow \infty} U\left(f_{i}\right)=\lim _{i \rightarrow \infty}$ $\int_{Y} f_{i} u d \mu$.

This follows immediately from the first two lemmas and from the obvious fact that the elements of $L^{1}$ form a dense set in $L^{p}$.

Lemma 4. If for each $E \boldsymbol{\varepsilon} \mathfrak{X}$ with $\mu(E)>0$ there is a function $f_{0} \varepsilon L^{p}-L^{1}$ such that $f_{0}(y)=0$ when $y \varepsilon Y-E$, and if $U$ is linear on $L^{p}$, then $U(f)=0$ for every $f \varepsilon L^{p}$.

Proof. If $U$ is not identically zero, the function $u$ of Lemma 3 cannot be almost everywhere zero; hence there is an $\alpha>0$ and a set $E \in X$ such that $|u(y)|>\alpha$ if $y \varepsilon E$. Let $f^{\prime}(y)=f_{0}(y)$ signum $f_{0}(y) \cdot u(y)$ where signum $s=|s| / s$ when $s \neq 0,=0$ when $s=0$; for each $n$ let $E_{n}=E_{y \varepsilon Y}\left[\left|f^{\prime}(y)\right| \leqq n\right]$, and let $f_{n}(y)=f^{\prime}(y)$ on $E_{n}, f_{n}(y)=0$ otherwise. Then $\left\|f_{n}-f^{\prime}\right\|_{p} \rightarrow 0$; also

$$
U\left(f_{n}\right)=\int_{Y} u f_{n} d \mu=\int_{E_{n}}\left|f_{0} u\right| d \mu \geqq \alpha \int_{E_{n}}\left|f_{0}\right| d \mu,
$$

but $E_{n} \uparrow E$ and $\int_{E}\left|f_{0}\right| d \mu=\infty$; so $U\left(f_{n}\right) \uparrow \infty$, contradicting continuity.
Lemma 5. If $q>1, E \in \mathfrak{X}$ and $\mu(E)>0$, and if no function $f$ which is zero on $Y-E$ belongs to $L^{1}-L^{q}$, then every $f \varepsilon L^{1}$ is essentially bounded on $E$.

Proof. If there is a function not essentially bounded on $E$, there is such a function $f_{0}$ which at the same time is zero on $Y-E$. Hence there exists a countably infinite sequence of sets $E_{n} \boldsymbol{\varepsilon} \mathfrak{X}$ with $\mu\left(E_{n}\right)=b_{n}>0, E_{n} \subset E, E_{n}$ disjoint, $\left|f_{0}(y)\right| \geqq n$ on $E_{n}$, and, since $f_{0} \varepsilon L^{q}, \sum n^{q} b_{n}<\infty$. Let $\alpha$ be so chosen that $1<\alpha<1 / q+q-1$ and let $a_{n}=1 / b_{n} n^{\alpha} ; \operatorname{let} f(y)=a_{n}$ if $y \varepsilon E_{n}, f(y)=0$ if $y \varepsilon Y-\sum_{n<\infty} E_{n}$. Then $\int_{Y}|f| d \mu=\sum_{n<\infty} a_{n} b_{n}=\sum n^{-\alpha}<\infty$, so $f \varepsilon L^{1}$. On the other hand $\int_{Y}|f|{ }^{q} d \mu=\sum a_{n}^{q} b_{n}=\sum b_{n}^{1-q} n^{-\alpha q}$. Since $\sum n^{q} b_{n}<\infty$ there must be a $K>0$ such that $n^{q} b_{n}<K$ for all $n$; this implies that $b_{n}^{1-q}>n^{q(q-1)} K^{1-q}$ so $\int_{Y}|f|^{q} d \mu \geqq K^{1-q} \sum n^{q(q-1)} n^{-\alpha q} \geqq K^{1-q} \sum n^{-1}=\infty$, and $f \notin L^{q}$ contrary to hypothesis.

For convenience we introduce a property of sets of $\mathfrak{X}$ : a set $E \boldsymbol{E}$ has property A relative to $\mu$ (in symbols $E \varepsilon \mathfrak{H}$ ) if $0<\mu(E)<\infty$ and for every $E^{\prime} \varepsilon \mathfrak{X}$ either ${ }^{9} \mu\left(E \cdot E^{\prime}\right)=0$ or $\mu\left(E-E^{\prime}\right)=0$.

There are several obvious properties of the sets of $\mathfrak{N}$.
(1) If $E$ has only one element and $\mu(E)>0$, then $E \boldsymbol{\varepsilon} \mathfrak{Y}$.

[^2](2) If $E \in \mathfrak{A}$ and $f$ is $\mathfrak{X}$-measurable, then $f$ is equal to a constant $\bar{f}$ almost everywhere on $E$.
(3) If $E_{1} \boldsymbol{\varepsilon} \mathfrak{H}$ and $E_{2} \boldsymbol{\varepsilon} \mathfrak{X}$, either $\mu\left(E_{1} E_{2}\right)=0$ or $\mu\left(E_{1} E_{2}\right)=\mu\left(E_{1}\right)$.
(4) $\mathfrak{A}$ is empty if and only if given $\epsilon>0$ it is possible to cover any set $E \varepsilon \mathfrak{X}$ with a countable collection of sets $S_{i} \varepsilon \mathfrak{X}$ with $\mu\left(S_{i}\right)<\epsilon$ for all $i$.
(5) If $E \varepsilon \mathfrak{A}$ and $\mu\left(E^{\prime}\right)=\mu\left(E^{\prime \prime}\right)=0$, then $E_{0}=E+E^{\prime}-E^{\prime \prime} \varepsilon \mathfrak{H}$ also.

Theorem 2. There is a nonzero linear functional on $L^{p}$ if and only if $\mathfrak{A}$ is not empty.

Proof. If $\mathfrak{H}$ is empty and $E \in \mathfrak{X}$ with $\mu(E)>0$, there is a sequence of disjoint subsets of $E$, each of positive measure. Hence there is a function in $L^{1}$ essentially unbounded on $E$; therefore, by Lemma 5 with $q=1 / p$, there is an $f \varepsilon L^{p}-L^{1}$ with $f(y)=0$ in $Y-E$; by Lemma 4 every linear functional on $L^{p}$ is identically zero.

On the other hand if there is a set $E \varepsilon \mathfrak{A}$, and if $\left\|f_{n}-f\right\|_{p} \rightarrow 0, f_{n}$ converges in measure to $f$; that is, for each $\epsilon>0, \mu\left(E_{y \varepsilon}\left[\left|f_{n}(y)-f(y)\right|\right.\right.$ $>\epsilon]) \rightarrow 0$ as $n \rightarrow \infty$. If $\bar{f}_{n}$ and $\bar{f}$ are the values of $f_{n}$ and $f$ almost everywhere on $E$, it follows that $\bar{f}_{n} \rightarrow \bar{f}$. Hence for any real number $k$ setting $U(f)=k \bar{f}$ defines a linear functional $U$ on $L^{p}$ and if $k \neq 0$ then $U$ is not identically zero.

For the case in which $m(E)$, the Lebesgue measure of $E$, is finite, Theorem 1 follows directly from Theorem 2 since every Lebesgue measurable set can be split into two subsets, each of measure half as great, so $\mathfrak{H}$ is empty for Lebesgue measure; the same conclusion could be derived from (4) above. The general case follows from this and from Theorem 6 below.

There are a large number of measures $\mu$ for which $\mathfrak{A}$ is empty. For example, to get one such class of measures, let $X$ be a separable metric space and $\mu$ a Carathéodory measure on the class $\mathfrak{X}$ of $\mu$-measurable sets; the class $\mathfrak{X}$, as is well known, contains all the Borel sets in $X$. If $Y$ is a measurable subset of $X$, we say that $\mu$ is a uniformly continuous function on $Y$ if the conditions $E_{n} \mathfrak{X}, E_{n} \subset Y$, and the sequence of diameters ${ }^{10} \delta\left(E_{n}\right) \rightarrow 0$ together imply that $\mu\left(E_{n}\right) \rightarrow 0$. It is easy to show from this condition that given $\epsilon>0$ there is a $\delta>0$ such that $\mu\left(E_{n}\right)<\epsilon$ whenever $E \varepsilon \mathfrak{X}, E \subset Y$ and $\delta(E)<\epsilon$.

Lemma 6. If $\mu$ is a Carathéodory measure on the separable space $X$, if $X=\sum Y_{j}$ with each $Y_{j} \boldsymbol{\varepsilon} \mathfrak{X}$ and $\mu\left(Y_{j}\right)<\infty$, and $\mu$ is uniformly continuous on each $Y_{j}$, then the class $\mathfrak{A}$ is empty.

[^3]Proof. If $E \varepsilon \mathfrak{A}$ and $\mu(E)=b>0$, we have by (3) that $\mu\left(E Y_{i}\right)=0$ if $i \neq j$, while $\mu\left(E Y_{j}\right)=b$; then by the separability of $X$ we can cover $Y_{j}$ with spheres of arbitrarily small radius. Hence by uniform continuity and (4) $\mu\left(E Y_{j}\right)=0$ also and $\mu(E)=0$, so $E$ cannot be in $\mathfrak{N}$.

Corollary. For such $X$ and $\mu$, if $\mu(X)<\infty$ there are no nonzero linear functionals on $L_{\mu}^{p}(X), 0<p<1$.

We remark that a later theorem allows us to remove the restriction that $\mu(X)<\infty$.

The interesting spaces $L_{\mu}^{p}(Y)$, then, are those for which the set $\mathfrak{A}$ is not empty; in such a case the structure of $\mathfrak{A}$ is rather simple.

Lemma 7. If $\mathfrak{A}$ is not empty, there exists a finite or countable sequence of sets $\left\{E_{i}\right\} \subset \mathfrak{H}$ such that every $E \boldsymbol{\varepsilon} \mathfrak{H}$ differs from just one $E_{i}$ only by sets of measure zero.

Proof. Well-order $\mathfrak{A}$, and define $E_{\alpha}$ to be the first set in the ordering which does not overlap any $E_{\beta}, \beta<\alpha$, on a set of positive measure. Since $\mu(Y)<\infty$, the number of these sets $E_{\alpha}$ for which $\mu(E)>1 / n$ must be finite for each $n$; hence the sequence $\left\{E_{\alpha}\right\}$ is finite or countable.

In what follows we shall let $\left\{E_{i}\right\}$ be the family of sets of $\mathfrak{H}$ of the preceding lemma, let $b_{i}=\mu\left(E_{i}\right)$ and let $\bar{f}_{i}$ be the value of the measurable function $f$ almost everywhere on $E_{i}$.

Theorem 3. Any linear functional on $L^{p}$ is identically zero, if $\mathfrak{A}$ is empty, or can be expressed in the form $U(f)=\sum_{i} u_{i} \bar{f}_{i}$ where $\|U\|=\sup _{i}\left|u_{i}\right| b_{i}^{-1 / p}$. If $u_{i}$ are given so that $\left|u_{i}\right|<K b_{i}^{1 / p}$ for all $i$, the functional $U(f)=\sum_{i} u_{i} f_{i}$ is linear on $L^{p}$.

Proof. It is easily seen from Theorem 2, applied to $L_{\mu}^{p}\left(Y-\sum_{i} E_{i}\right)$, that $U(f)$ is independent of the values of $f$ on $Y-\sum_{i} E_{i}$; hence no generality is lost if we assume $Y=\sum_{i} E_{i}$ for simplicity. Let $f_{(i)}$ be the characteristic function of $E_{i}$ (that is, $f_{(i)}(y)=1$ if $y \varepsilon E_{i}, f_{(i)}(y)=0$ otherwise), and take any $f \varepsilon L^{p}$; then $\left\|\sum_{i \leqq n} \bar{f}_{i} f_{(i)}-f\right\|_{p \rightarrow 0}$ as $n \rightarrow \infty$; so, by continuity, $U(f)=\lim _{n} U\left(\sum_{i \leqq n} \bar{f}_{i} f_{(i)}\right)=\lim _{n} \sum_{i \leq n} \bar{f}_{i} U\left(f_{(i)}\right)=\sum_{i} u_{i} \bar{f}_{i}$ where $u_{i}=U\left(f_{(i)}\right)$. Postponing the computation of $\|U\|$ for a moment, let us assume $u_{i}$ given such that $\left|u_{i}\right| \leqq K b_{i}^{1 / p}$, and take $\|f\|_{p}=1$. Then $\left|\bar{f}_{i} b_{i}^{1 / p}\right| \leqq\|f\|_{p} \leqq 1$, so that $\left|\bar{f}_{i}\right| b_{i}^{1 / p} \leqq\left|\bar{f}_{i}\right|^{p} b_{i}$ since $0<p<1$. Therefore $|U(f)| \leqq \sum_{i}\left|u_{i} \bar{f}_{i}\right| \leqq K \sum_{i}\left|b_{i}^{1 / p} \bar{f}_{i}\right| \leqq K \sum_{i}\left|\bar{f}_{i}\right|^{p} b_{i} \leqq K$, so $U$ is bounded; hence it is continuous, and $\|U\| \leqq K$. It follows, if $K=\sup _{i}\left|u_{i}\right| b_{i}^{-1 / p}$, that $\|U\| \geqq K$ also for $\left|U\left(b_{i}^{-1 / p} f_{(i)}\right)\right|=\left|u_{i}\right| b_{i}^{-1 / p} \leqq\|U\|$; therefore $\sup _{i}\left|u_{i}\right| b_{i}^{-1 / p} \leqq\|U\|$ also. We note that this shows that the series $\sum_{i}\left|u_{i} \bar{f}_{i}\right|$ converges.

We now turn to the case in which $\mu(Y)$ need not be finite; for greater convenience we introduce another property of sets relative to $\mu ; Y$ has property B (in symbols $Y \varepsilon \mathfrak{B}$ ) if $Y$ can be expressed as $\sum_{j<\infty} Y_{j}$ with $Y_{j} \varepsilon \mathfrak{X}$ and $\mu\left(Y_{j}\right)<\infty$ for each $j$.

Clearly Lemma 7 holds if $Y \varepsilon \mathfrak{B}$ as well as if $\mu(Y)<\infty$; we let $E_{i}, b_{i}$ and $\bar{f}_{i}$ have their previous meanings.

Theorem 4. If $Y \varepsilon \mathfrak{B}$, a functional $U$ on $L_{\mu}^{p}(Y)$ is linear if and only if (a) it is identically zero and $\mathfrak{H}$ is empty, or (b) $\mathfrak{A}$ is not empty and $U$ can be expressed in the form $U(f)=\sum_{i} u_{i} \bar{f}_{i}$ with $\|U\|=\sup _{i}\left|u_{i}\right| b_{i}^{-1 / p}$.

Proof. The sets $Y_{j}$ which exist by property B can obviously be taken disjoint; we let $U_{j}$ be a linear functional on $L_{\mu}^{p}(Y)$ defined by $U_{j}(f)=U\left(f_{j}^{\prime}\right)$ where $f_{j}^{\prime}(y)=f(y)$ when $y \varepsilon Y_{j}, f_{j}^{\prime}(y)=0$ otherwise. Then $U_{j}$ is linear on $L_{\mu}^{p}\left(Y_{j}\right)$; so by Theorems 2 and 3 either $U_{j}$ is identically zero or $U_{j}(f)=\sum_{i} u_{j i} \bar{f}_{j i}$. Now $\lim _{n}\left\|\sum_{i \leqq n} f_{i}^{\prime}-f\right\|_{p}=0$, so $U(f)=\lim _{n} \sum_{j \leqq n} U\left(f_{j}^{\prime}\right)=\sum_{j} U_{j}(f)$. Moreover there is an $f_{0} \varepsilon L^{p}$ such that $\left|f_{0}(y)\right|=|\bar{f}(y)|$ for all $y \varepsilon Y$ and $U_{j}\left(f_{0}\right)=\left|U_{j}(f)\right|$ for all $j$; hence $\left|U_{j}(f)\right| \leqq \sum_{j} U_{j}\left(f_{0}\right)=U\left(f_{0}\right) \leqq\|U\| \cdot\left\|f_{0}\right\|=\|U\| \cdot\|f\|$, so $\left\|U_{j}\right\| \leqq\|U\|$ and the series $\sum_{j} U_{j}(f)$ converges absolutely for all $f \varepsilon L_{\mu}^{p}$. Then $\left|u_{j i}\right| b_{\bar{j} i}^{1 / p} \leqq\left\|U_{i}\right\| \leqq\|U\|$ and $U(f)=\sum_{i} \sum_{i} u_{j i} \bar{f}_{j i}$ unless all $U_{j}$ are identically zero, that is, unless $\mathfrak{A}=0$. Rearranging this into a simple series, permissible since it converges absolutely, we get $U(f)=\sum u_{i} f_{i}$. The other conclusions follow as in Theorem 3.

The general form of Theorem 1 follows directly from this, since the whole euclidean space is the sum of a countable set of finite intervals.

There remains the case in which $Y$ is not in $\mathfrak{B}$. As we did in the proof of Lemma 7, we can define a well-ordered set $\left\{E_{\gamma}\right\}$ of sets of $\mathfrak{H}$, disjoint up to sets of measure zero and such that every $E \boldsymbol{\varepsilon} \mathfrak{H}$ is, except for sets of measure zero, equal to some $E_{\gamma}$; however we have no assurance that the sequence will be countable. As before we let $b_{\gamma}=\mu\left(E_{\gamma}\right)$ and $\bar{f}_{\gamma}$ be the value of $f$ almost everywhere on $E_{\gamma}$. We need also a known lemma about the set in which a function in $L_{\mu}^{p}(Y)$ is not equal to 0 .

Lemma 8. For every $q>0$ and any $f \varepsilon L_{\mu}^{q}(Y), E_{0}=E_{y}[f(y) \neq 0] \varepsilon \mathfrak{B}$.
Proof. Since $f \varepsilon L^{q}$ means $|f|^{q} \varepsilon L^{1}$, we need only consider $L_{\mu}^{1}(Y)$ and may suppose that $f(y)>0$ for all $y \varepsilon Y$. By definition of the integral (see Saks, p. 19 ff .) $\int_{Y} f d \mu=\sup _{g} \int_{Y} g d \mu$ where the sup is taken over those functions $g$ which are linear combinations of characteristic functions of sets of $\mathfrak{X}$ and which at the same time satisfy the inequalities $0 \leqq g(y) \leqq f(y)$ for almost all $y \boldsymbol{\varepsilon} Y$. But such a function can be different from zero only on a set of finite measure if it is to have a
finite integral. There is a sequence $\left\{g_{i}\right\}$ of these functions such that $g_{i} \uparrow f$ almost everywhere in $Y$ and $\int_{Y} f d \mu=\lim _{i} \int_{Y} g_{i} d \mu$; hence the set where $f>0$ is, except for a set of measure zero, the sum of the sets on which the $g_{i}>0$, and each of these sets is of finite measure.

By this lemma it is possible to put each function $f$ of $L_{\mu}^{p}(Y)$ into at least one class $C_{E}$ such that $f(y)=0$ in $Y-E$ and $E \in \mathfrak{B}$; then $C_{E}$ is equivalent to $L_{\mu}^{p}(E)$, and, if we set $U_{E}(f)=U(f)$ for $f \varepsilon C_{E}, U_{E}$ is linear on $L_{\mu}^{p}(E)$ and therefore can be expressed as before where the $E_{i}$ of Theorem 4 will be those $E_{\gamma}$ which, except for sets of measure zero, lie in $E$. But $f=0$ on $Y-E$; so we can write $U(f)=\sum_{\gamma} u_{\gamma} \bar{f}_{\gamma}$ if it is not identically zero, with the convention that the sum of any number of terms in which $\bar{f}_{\alpha}$ or $u_{\alpha}$ is zero shall be zero. Since this can be done for each $f \varepsilon L_{\mu}^{p}(Y)$, we get our final result, including the previous theorems as special cases.

Theorem 5. A functional $U$ on $L_{\mu}^{p}(Y)$ is linear if and only if (a) $\mathfrak{A}$ is empty and $U$ is identically zero or (b) $\mathcal{N}$ is not empty and $U$ can be expressed in the form $U(f)=\sum_{\gamma} u_{\gamma} \bar{f}_{\gamma}$ and $\|U\|=\sup _{\gamma}\left|u_{\gamma}\right| b_{\gamma}{ }^{-1 / p}$.

If we let $L^{p *}$ be the space of linear functionals on $L_{\mu}^{p}(Y)=L^{p}$, it is clear that with the given norm $L^{p *}$ is a Banach space. To make the study of its structure simpler we introduce the class $\Gamma$ of ordinal numbers as follows; If $\mathfrak{A}$ is empty, $\Gamma$ is also empty; if $\mathfrak{A}$ is not empty, $\Gamma$ is the class of ordinals used in ordering the sets $E_{\gamma}$ of $\mathfrak{N}$ defined above. We use $x=\left\{x_{\gamma}\right\}$ to stand for a real-valued function on $\Gamma$ and define the special function $x_{\gamma}$ to have the value 1 at $\gamma$ and 0 elsewhere. Let $M=M(\Gamma)$ be the class of bounded functions $x$ with $\|\mathrm{x}\|_{M}=\sup _{\boldsymbol{\gamma} \boldsymbol{\varepsilon} \Gamma}\left|x_{\gamma}\right| ;$ for any $q>0$ let $L^{q}=L^{q}(\Gamma)$ be the class of all x such that $\|\mathrm{x}\|_{q}=\left(\left.\left.\sum_{\gamma \varepsilon \mathrm{r}}\right|_{x_{\gamma}}\right|^{q}\right)^{1 / q}<\infty$.

It is clear that the space $L^{q}(\Gamma)$ here defined is also the space $L_{\mu_{0}}^{q}(\Gamma)$ where $\mu_{0}$ is the trivial measure assigning the measure 1 to each set containing just one point $\gamma$ and $\mathfrak{X}$ is the smallest additive family on the countable sets in $\Gamma$. From Theorem 5 we have this result:

Theorem 6. If $\Gamma$ is not empty, a functional $U$ on $L^{p}$ is linear if and only if it can be expressed as $U(\mathrm{x})=\sum_{\gamma \varepsilon \mathrm{\Gamma}} u_{\gamma} x_{\gamma}$ where $\|U\|=\sup _{\gamma \varepsilon \mathrm{F}}\left|u_{\gamma}\right|$.

Considering again the space $L^{p *}$, it is clear that when $\mathfrak{A}$ is not empty the transformation which associates the element $U \varepsilon L^{p *}$ defined by $U(f)=\sum_{\gamma \varepsilon \Gamma} u_{\gamma} \bar{f}_{\gamma}$ with the element $u=\left\{u_{\gamma} b_{\gamma}^{-1 / p}\right\} \varepsilon M$ is one-to-one, linear both ways and norm-preserving between all of $L^{p *}$ and all of $m$; but this is precisely the definition of equivalence of two Banach spaces (Banach, p. 180); hence:
(6) $L^{p *}$ and $m$ are equivalent Banach spaces.

This holds even for the case in which $\mathfrak{A}$ is empty if we define $M(\Gamma)$ for $\Gamma$ empty to be the Banach space with just one element, the zero element.

Slightly modifying our previous usage, we let $f_{(\gamma)}$ be $b_{\gamma}^{-1 / p}$ on $E_{\gamma}$ and be zero elsewhere. If we extend the definition of equivalence of Banach spaces in the obvious way to these $L^{p}$ spaces we get this result:

Theorem 7. $L_{\mu}^{p}\left(\sum_{\gamma \varepsilon \Gamma} E_{\gamma}\right)$ is equivalent to $L^{p}(\Gamma)$ under the linear transformation for which $T f=\mathrm{x}$, where $\mathrm{x}=\left\{\mathrm{x}_{\gamma}\right\}=\left\{\bar{f}_{\gamma} b_{\gamma}^{1 / p}\right\}$; that is, which takes $f_{(\gamma)}$ to $\mathbf{x}_{\gamma}$.

Proof. By linearity if $f=\sum_{\gamma} x_{\gamma} f_{(\gamma)}, T f=\mathrm{x}$ must be $\sum_{\gamma} x_{\gamma} \mathrm{x}_{\gamma}$. Now $\|f\|_{p}=\left(\sum\left|x_{\gamma}\right|^{p}\right)^{1 / p}$ and $\|\mathrm{x}\|_{p}=\left(\sum\left|x_{\gamma}\right|^{p}\right)^{1 / p}$; so the transformation is one-to-one on all $L^{p}$ and $L^{p}$ and $\|T f\|=\|f\|$ for all $f \varepsilon L^{p}\left(\sum_{\gamma} E_{\gamma}\right)$; so the spaces are equivalent.

Corollary. If $\Gamma^{\prime}$ is any set of ordinals and $\Gamma^{\prime} \subset \Gamma$, then $L^{p}\left(\Gamma^{\prime}\right)$ is equivalent to the subspace $L_{\mu}^{p}\left(\sum_{\gamma \varepsilon \Gamma^{\prime}} E\right)$ of $L_{\mu}^{p}(Y)$.

Since, as is well known, $L^{1 *}=M$, the following relation between $L^{p}$ and $L^{1}$ is not entirely unexpected.
(7) If we define on the subspace $L_{\mu}^{p}\left(\sum_{\gamma \varepsilon \Gamma} E_{\gamma}\right)$ of $L_{\mu}^{p}(Y)$ the transformation $T$ by associating to $f=\sum_{\gamma \varepsilon \Gamma^{1}} x_{\gamma} f_{(\gamma)}$ the function $T f=\mathbf{x}$ $=\sum_{\gamma} x_{\gamma} x_{\gamma}$, then $T$ is linear on $L_{\mu}^{p}\left(\sum_{\gamma \varepsilon \Gamma} E_{\gamma}\right)$ to $L^{1}$ and $\|T\|=1$.

In general, if $\Gamma$ is not a finite set, the set of all $T f$ with $f \varepsilon L_{\mu}^{p}\left(\sum_{\gamma \varepsilon T} E_{\gamma}\right)$ is not all of $L^{1}$.

We conclude with some elementary remarks about the cases when $\Gamma$ is a finite set; then the spaces $L^{q}(\Gamma), q>0$, can be gotten by giving a new pseudo-norm to an $n$-dimensional euclidean space. When $q \geqq 1$ this pseudo-norm is actually a norm and the "spheres" $E_{x}[\|x\| \leqq \epsilon]$ are convex point sets, and we have some of the well known Minkowski spaces. When $0<q<1$ these sets are not convex but each contains an ordinary euclidean sphere and is contained in another such sphere, so the topology in all these $L^{q}(\Gamma)$ is the same as that in, say, $L^{2}(\Gamma)$, the space with euclidean metric. Convergence in $M(\Gamma)$ is also the same as that in $L^{2}(\Gamma)$ when $\Gamma$ is finite. However these spaces are not in general equivalent as Banach spaces; if $\Gamma=\{1\}$, all are equivalent Banach spaces; if $\Gamma=\{1,2\}, L^{1}(\Gamma)$ and $M(\Gamma)$ are equivalent; none of the others are.
