PERTURBING ALMOST PERIODIC
DIFFERENTIAL EQUATIONS

BY SHUI-NEE CHOW

Communicated by Fred Brauer, September 2, 1969

ABSTRACT. When the zero solution of an almost periodic dif­
ferential system is uniform-asymptotically stable, it is shown that
the zero solution is diminishingly asymptotically stable and
totally asymptotically stable. Generalization of the above theorem
to bounded solutions and functional differential equations with
finite time-lag are obtained by the same method. The techniques
used in the proof also give a more general approach to perturba­
tion theory of differential equations.

1. Consider a system of differential equations
\[ x' = f(t, x) \]
and its perturbed equations
\[ x' = f(t, x) + p(t). \]

We always assume at least that:

(i) \( f(t, x) \) is defined on \([0, \infty) \times S_c\), where \( S_c = \{ x \in \mathbb{R}^d : |x| < c, c > 0 \} \), such that \( f(\cdot, x) \) is measurable for each \( x \), \( f(t, \cdot) \) is continuous
for each \( t \), and \( f \) is bounded on every compact subset of \([0, \infty) \times S_c\);
(ii) \( p(t) \) is defined and measurable on \([0, \infty)\).

In a recent paper Strauss and Yorke [2] have shown (for defini­
tions, see §4)

THEOREM 1. Suppose the origin 0 is uniform-asymptotically stable
(UAS) for (E), and \( f \) belongs to the class of Lipschitz or linear or inner-
product or periodic functions. Then for every absolutely diminishing \( p(t) \), the origin 0 is eventually uniform-asymptotically stable (EvUAS)
for (P).

For a detailed discussion of Theorem 1, refer to [2].

A natural question is: does this theorem hold if \( f(t, x) \) is almost peri­
odic? An answer is given in Theorem 2.

2. Define \( f_\tau(t, x) = f(t+\tau, x) \) and \( H(f) = \{ f_\tau : \tau \in \mathbb{R} \} \). \( \overline{H(f)} \) denotes
the closure of \( H(f) \) in the sense of uniform convergence on all of
\( R \times S \), for any compact subset \( S \subseteq S_c \).

Definition. A continuous function \( f: \mathbb{R} \times S_c \rightarrow \mathbb{R}^d \) is said to be almost periodic in \( t \) uniformly in \( x \) if for all \( \epsilon > 0 \), for all compact subsets \( S \subset S_c \), there exists \( k = k(\epsilon, S) > 0 \), such that for every interval \((a, a+k)\), there exists \( \tau \in (a, a+k) \) such that

\[
| f(t, x) - f(t, x') | < \epsilon, \quad \text{for all } t \in R, x \in S.
\]

Bochner's theorem. \( f \) is almost periodic in \( t \) uniformly in \( x \) on \( R \times S_c \) if and only if \( \mathbb{H}(f) \) is compact.

Theorem 2. Suppose the origin 0 is UAS for \( (E) \), \( \mathbb{H}(f) \) is compact, and for every \( g \in \mathbb{H}(f) \) solutions of \( x' = g \) are unique to the right. Then \( x = 0 \) is integrally asymptotically stable for \( (E) \). This implies [1] for every absolutely diminishing \( \rho(t) \), the origin 0 is \( \text{EvUAS} \) for \( (P) \).

Outline of the proof of Theorem 2. Given \( \eta > 0, x \in S_c, g \in \mathbb{H}(f), t \in [0, \infty) \), let \( R(\eta; x, g, t) \) be a set in \( S \times \mathcal{H} \), which consists of all the points \((\phi(t), g_t)\) for which \( \phi(\cdot) \) is an absolutely continuous function defined on \([0, \infty)\),

\[
\int_0^\infty \left| \phi'(s) - g(s, \phi(s)) \right| \, ds < \eta \quad \text{and} \quad \phi(0) = x.
\]

It is not difficult to show that if for every \( \epsilon > 0 \), there exist \( \delta > 0, \eta > 0 \) such that \( |x| < \delta \) implies \( R(\eta; x, g, t) \subset S(0 \times \mathcal{H}, \epsilon) \), for all \( t \geq 0 \), \( g \in \mathbb{H}(f) \), then the origin 0 is integrally stable for \( x' = f \). Further, the origin 0 is integrally attracting for \( x' = f \) if there exists \( \delta_0 > 0 \), and for every \( \epsilon > 0 \), there exist \( T > 0, \eta > 0 \) such that \( |x| < \delta_0 \) implies \( R(\eta; x, g, t) \subset S(0 \times \mathcal{H}, \epsilon) \), for all \( t \geq T \), \( g \in \mathbb{H}(f) \). \( S(0 \times \mathcal{H}, \epsilon) \) denotes the \( \epsilon \)-ball containing the set \( 0 \times \mathcal{H} \) in the metric space \( R^d \times \mathcal{H} \).

Lemma 1. Suppose \( \mathbb{H}(f) \) is compact, and for every \( g \in \mathbb{H}(f) \), solutions of \( x' = g \) are unique to the right. Let \( T > 0, S \subset S_c \) be a compact subset and \( c' < c \). Assume that \( F(t, x, g) \in S_{c'} \) for every \( g \in \mathbb{H}(f), x \in S, \) and \( t \in [0, T] \).

Then for every \( \epsilon > 0 \), there exists \( \eta(\epsilon) > 0 \) such that

\[
\int_0^T | \rho(t) | \, dt < \eta \quad \text{implies} \quad | F(t, x, g) - F(t, x, g + \rho) | < \epsilon
\]

for all \( t \in [0, T] \) and \( g \in \mathbb{H}(f) \), where \( F(t, x, g) \) denotes the solution of \( x' = g \) through \((0, x)\).

By using a similar method, we obtain
THEOREM 3. Under the assumptions of Theorem 2, the origin 0 is totally asymptotically stable for (E).

3. There are examples due to J. Kato and J. Yorke in which \( \overline{H}(f) \) is compact, \( f \) is locally Lipschitz, the origin 0 is UAS for (E), and the origin 0 is not totally stable. The reason is that there are functions \( g \in \overline{H}(f) \) for which the uniqueness requirement is not met.

By using a different topology on \( \overline{H}(f) \), we can obtain a different class of functions for which the conclusions of Theorems 2 and 3 hold. For example, if we use the compact-open topology, Theorems 2 and 3 hold with \( f \) satisfying the condition that \( f \) is bounded and uniformly continuous, on every set \( R \times S \), where \( S \) is a compact subset of \( S \). An example given by Strauss and Yorke [2] shows that this is, in a sense, the best possible result one can obtain.

There is an analog of Theorems 2 and 3 for functional differential equations with finite lag. The author learned that recently Theorem 3 for functional differential equation with finite lag has also been obtained by T. Yoshizawa and J. Kato, independently [3].

Similar results have been obtained in certain cases of nonuniqueness.

It is not hard to show that the above theorems still hold in case the perturbation depends on \( x \), that is, \( \rho \) has the form \( \rho(t, x) \).

Details of this paper will appear elsewhere.

4. Let \( F(t; t_0, x_0, f) \) denote a solution of (E) through the point \( (t_0, x_0) \), and let \( F(t; t_0, x_0, f) = F(t; 0, x_0, f) \).

The solution \( x = 0 \) is said to be integrally stable for (E) if for every \( \epsilon > 0 \), there exist \( \delta(\epsilon) > 0 \) and \( \eta(\epsilon) > 0 \) such that \( |x_0| < \delta \) and

\[
(1) \quad \int_{t_0}^{\infty} |\rho(t)| \, dt < \eta
\]

imply, for all \( t \geq t_0 \geq 0 \),

\[
(2) \quad |F(t; t_0, x_0, f + \rho)| < \epsilon.
\]

If, in addition, there exists \( \delta_0 > 0 \), and corresponding to any given \( \epsilon > 0 \), there are \( T(\epsilon) \geq 0 \) and \( \eta(\epsilon) > 0 \) such that \( |x_0| < \delta_0 \) and inequality (1) implies inequality (2) for \( t \geq T + t_0 \), then \( x = 0 \) is said to be integrally asymptotically stable for (E). The second property alone is called integral attraction of the zero solution for (E).

If we replace (1) by

\[
(3) \quad |\rho(t)| < \eta, \quad t \geq t_0
\]
then we have the definition of $x = 0$ being *totally stable* (respectively *totally asymptotically stable*) for (E).

The origin 0 is said to be EvUAS for (E) if there exist $\delta_0 > 0$ and $\alpha_0 \geq 0$, and for every $\epsilon > 0$, there exist $\alpha(\epsilon) > 0$, $\delta(\epsilon) > 0$, and $T(\epsilon) > 0$ such that $|x_0| < \delta$, $t \geq t_0 \geq \alpha(\epsilon)$ implies $|F(t, t_0, x_0, f)| < \epsilon$ and $|x_0| < \delta_0$, $t_0 \geq \alpha_0$, $t \geq T + t_0$ implies $|F(t; r_0, x_0, f)| < \epsilon$.

A measurable function $p: [0, \infty) \rightarrow \mathbb{R}^d$ is said to be absolutely diminishing if

$$\int_t^{t+1} |p(s)| \, ds \rightarrow 0 \quad \text{as} \quad t \rightarrow \infty.$$
