EUCLIDEAN SUBRINGS OF GLOBAL FIELDS

BY CLIFFORD S. QUEEN

Communicated by Hyman Bass, October 20, 1972

1. Introduction. The purpose of this note is to announce some results regarding the existence of euclidean subrings of global fields.

We first state the problem and give its history. Let $F$ be a global field. So $F$ is a finite extension of the rational numbers $Q$ or $F$ is a function field of one variable over a finite field $k$, where $k$ is algebraically closed in $F$. Let $S$ be a finite nonempty set of prime divisors of $F$ such that $S$ includes all infinite (i.e., archimedean) prime divisors. If $P$ is a finite (i.e., nonarchimedean) prime divisor we denote by $O_P$ its valuation ring in $F$. Now, given a finite set $S$ of the above type, we get a ring

$$O_S = \bigcap_{P \in S} O_P$$

where $P$ ranges over all prime divisors of $F$. We note in particular that if $F$ is a number field and $S$ the set of infinite prime divisors of $F$ then $O_S$ is just the ring of $F$-integers.

It is easy to see that there always exists a finite set $S$ satisfying the above hypothesis such that $O_S$ is a unique factorization domain. Hence it seems natural to ask the following two questions:

I. Does there always exist an $S$ such that $O_S$ is a euclidean ring?

II. Can one find an algorithm on $O_S$ for suitably chosen $S$ which is related in some way to the arithmetic of the field $F$?

The history of the above two questions is as follows: In a series of articles [1]–[4] Armitage discussed I and II for function fields over arbitrary ground fields. He insisted on a choice of algorithm related to the norm from $F$ to a rational subfield. He showed that if the ground field of $F$ is infinite, then an algorithm of his spacial type was possible if and only if the genus of $F$ is zero. He also discussed the case when the ground field of $F$ is finite, but again the only situation in which he gave a positive answer to I was when $F$ is of genus zero. In [6], Samuel also discussed I for function fields $F$ with arbitrary fields of constants, but here also he did not get above genus zero. Finally, in [5], M. Madan and the present author showed that the answer to both I and II is yes for function fields of genus one over finite fields. The method in [5] was to specifically construct an $S$ and an algorithm on $O_S$ for given $F$.

AMS (MOS) subject classifications (1970). Primary 12A05; Secondary 12A05.

Key words and phrases. Euclid's algorithm, adeles, global fields.

ADDED IN PROOF. After this announcement went to press, the author discovered that Theorem 2 was proved by O. T. O'Meara in On the finite generation of linear groups over Hasse domains, J. Reine Angew. Math. 217 (1965), 79–108. MR 31 #3513.

In the next section we indicate a proof that the answer to both I and II is yes for arbitrary global fields $F$. Full details of the proof and applications of the results will appear elsewhere.

2. Results. Let $F$ be a global field. If $P$ is a finite prime divisor of $F$ we denote by $N(P)$ the absolute norm of $P$ and we associate with each such $P$ a normalized valuation $| \cdot |_P$ as follows: $|O_P|_P = 0$ and if $x \in F - \{0\} = F^*$, then $|x|_P = N(P)^{-n}$, where $P^n$ is the power to which $P$ appears in the principal divisor $(x)$ determined by $x$ in $F$. Now if $P$ is an infinite prime divisor then $P$ corresponds to an embedding $\sigma_P$ of $F$ into the complex numbers and we determine a normalized valuation $| \cdot |_P$ associated to $P$ in the following way: If $\sigma_P(F)$ is a subfield of the real numbers then $|x|_P = |\sigma_P(x)|$ for all $x \in F$, where $| \cdot |$ is the ordinary real absolute value. Finally if $\sigma_P(F)$ is not a subfield of the reals, we set $|x|_P = |\sigma_P(x)|^2$ for all $x \in F$, where $| \cdot |$ is the usual complex absolute value. Hence letting $P$ range over all prime divisors of $F$, we have the well-known formula

$$\prod_P |x|_P = 1$$

for all $x \in F^*$.

If $P$ is a prime divisor of $F$ we denote by $F_P$ the completion of $F$ with respect to the valuation $| \cdot |_P$. These fields $F_P$ are all locally compact and if $P$ is finite we denote by $R_P$ the maximal compact subring of $F_P$. We call the restricted topological product of the $F_P$ with respect to the $R_P$ the ring of adeles of $F$ and denote it by $F_A$. We further identify $F$ with its diagonal embedding in $F_A$.

Now if $F$ is a number field we denote by $S_\infty$ the set of infinite prime divisors of $F$ and if $F$ is a function field over a finite field we fix a prime divisor $P^\circ$ of $F$ and set $S_\infty = \{P^\circ\}$. Next if $x \in F^*$ we set

$$V(x) = \{\zeta \in F_A | |\zeta|_P < |x|_P \text{ for } P \in S_\infty \text{ and } |\zeta|_P \leq |x|_P \text{ for } P \notin S_\infty\}.$$

**Theorem 1.**

$$F_A = \bigcup_{x \in F^*} (V(x) + F).$$

**Indication of Proof.** If $F$ is a function field and $k$ its exact field of constants we use the Riemann-Roch theorem to choose $t \in F$ such that $F/k(t)$ is a separable extension and $|t|_{P_\infty} > 1$, with $|t|_P \leq 1$ for all $P \neq P_\infty$. If $F$ is a number field we let $H$ denote the field of real numbers and otherwise $H$ will denote $k((t^{-1}))$, where $k((t^{-1}))$ is the quotient field of the ring of formal power series in $t^{-1}$ over $k$. Next we set $F_\infty = F \otimes_L H$, where $L = Q$ if $F$ is a number field and $L = k(t)$ otherwise. Viewing $F_\infty$ as a topological algebra over $H$ we identify it with the subalgebra of $F_A$, $\prod_{P \in S_\infty} F_P$. 

Setting $X = F \times \prod_{P \in S} R_P$, we observe that $F_A = X + F$ (see [7]). Let $\{\omega_1, \ldots, \omega_n\}$ be an integral basis of $F$ over $L$ with respect to $\Gamma$, where $\Gamma$ is the ring of rational integers if $F$ is a number field and otherwise $\Gamma = k[t]$. Finally we show that if $\zeta \in X$, then there exist $q, p_1, \ldots, p_n \in \Gamma$ such that $q \neq 0$ and $q\zeta - (p_1\omega_1 + \cdots + p_n\omega_n)$ has the property that

$$|(q\zeta - (p_1\omega_1 + \cdots + p_n\omega_n))|_P < 1 \quad \text{for } P \in S_{\infty},$$

and

$$|(q\zeta - (p_1\omega_1 + \cdots + p_n\omega_n))|_P \leq 1 \quad \text{for } P \notin S_{\infty},$$

i.e., $\zeta \in V(q^{-1}) + F$. Q.E.D.

Let $S$ be a finite set of prime divisors of $F$ such that $S \supseteq S_{\infty}$. We define a function $\varphi_S$ from $F$ to the nonnegative real numbers given by $\varphi_S(x) = \prod_{P \in S} |x|_P$. We note that, in view of (1), $\varphi_S$ is integral valued when restricted to $O_S$. Further in the case when $F$ is a number field and $S = S_{\infty}$, then, for all $x \in F$, $\varphi_S(x) = |N_{F/Q}(x)|$. Also when $F$ is a function field, then for any choice of $S \supseteq S_{\infty}$, there exist $y \in F - k$ such that $O_S$ is the integral closure of $k[y]$ in $F$ and, for all $x \in F$, $\varphi_S(x) = |N_{F/k}(y)|_{\infty}$, where $| \cdot |_{\infty}$ is the valuation associated to the pole divisor of $y$ in $k(y)$ and normalized as above.

**Theorem 2.** There exists a finite set $S$ of prime divisors of $F$ such that $S \supseteq S_{\infty}$ and $O_S$ is euclidean with respect to the map $\varphi_S$.

**Indication of Proof.** By Theorem 1, $F_A = \bigcup_{x \in F^*} (V(x) + F)$. Now by compactness of $F_A/F$ (see [7]) and the fact that $V(x)$ is open in $F_A$ for every $x \in F$, there exist $x_1, \ldots, x_r \in F^*$ such that

$$F_A = \bigcup_{i=1}^r (V(x_i) + F).$$

Finally we show that if $S = \{P|P \in S_{\infty} \text{ or there exist } i_0, 1 \leq i_0 \leq r \text{ such that } |x_{i_0}|_P \neq 1\}$, then $S$ is a finite set, $S \supseteq S_{\infty}$ and $O_S$ is euclidean with respect to $\varphi_S$.
