ROTUNDITY, ORTHOGONALITY, AND CHARACTERIZATIONS
OF INNER PRODUCT SPACES

BY J. R. HOLUB

Communicated by Alston Householder, May 30, 1975

1. The purpose of this paper is to announce a number of interesting new
results concerning the geometry of normed linear spaces. In particular, we
present some new characterizations of rotund normed linear spaces and of inner
product spaces. The general theme connecting the two topics is the realization
that special cases of conditions characterizing inner product spaces are often in
themselves characterizations of rotundity.

Details and proofs will appear elsewhere.

Throughout the paper $E$ will denote a real normed linear space (n.l.s.) and
$M$ a subspace of $E$, denoted $M \subset E$. If $\{x_i\}_{i=1}^n$ is a subset of $E$, $[x_i]_{i=1}^n$ will
denote the linear span of $\{x_i\}$.

2. Rotundity. Recall that a n.l.s. $E$ is said to be rotund [3] (or strictly
convex [2]) if every point on the unit sphere in $E$ is an extreme point. Our first
result shows that rotundity is characterized by a very desirable condition involving
the cone in $E$ generated by a set of vectors.

**DEFINITION 1.** Let $\{*,\}$, $^{\neq}i=1$ be a normalized linearly independent pair of
vectors in $E$. Then $C\{x_t\} = \{a_1 x_1 + a_2 x_2 | a_1 \cdot a_2 > 0\}$ is called the cone
of $\{x_i\}_{i=1}^2$ in $E$.

**THEOREM 1.** $E$ is rotund $\iff$ for any normalized linearly independent set
$\{x_i\}_{i=1}^2$ in $E$, the set of points in $[x_i]_{i=1}^2$ equidistant from $x_1$ and $x_2$ is a subset
of $C\{x_i\}$.

Another characterization of rotundity which has a similar flavor is based on
the following lemma which is interesting in its own right.

**LEMMA 1.** Let $E$ be a 2-dimensional n.l.s. Then every point $x \in E$ with
$\|x\| < 1$ is the midpoint of a chord of the unit sphere in $E$ (i.e. there exist $x_1$ and
$x_2$ with $\|x_1\| = \|x_2\| = 1$ for which $x = (1 - \lambda)x_1 + \lambda x_2$, $0 < \lambda < 1$).

A natural question concerns the uniqueness of such a chord (for $x \neq 0$).

THEOREM 2. \( E \) is rotund \( \iff \) given any two-dimensional subspace \( M \subset E \) and any \( x \in M \) with \( 0 < \|x\| < 1 \), then \( x \) is the midpoint of a unique chord of the unit sphere in \( M \).

Another result of a similar nature is

THEOREM 3. \( E \) is rotund \( \iff \) given any two-dimensional subspace \( M \subset E \) and any \( x \in M \) with \( 0 < \|x\| \leq 1 \) there exists a unique pair of normalized vectors \( x_1 \) and \( x_2 \) in \( M \) for which \( x = x_1 + x_2 \).

A final result links rotundity to the number of linearly independent points which norm a projection on \( E \).

DEFINITION 2. If \( E \) and \( F \) are n.l.s. and \( T: E \rightarrow F \) a bounded linear operator, a point \( x \in E \) for which \( \|x\| = 1 \) and \( \|Tx\| = \|T\| \) is called a norming point of \( T \).

THEOREM 4. \( E \) is rotund \( \iff \) given any n-dimensional subspace \( M \subset E \) \((1 < n < +\infty)\) and any projection \( P: E \rightarrow M \), then \( P \) has at most \( n \) linearly independent norming points.

3. Orthogonality and inner product spaces. Several (nonequivalent) definitions of orthogonality in n.l.s. have been given by various authors. Two of these are

DEFINITION 3 (Birkhoff [1]). \( x \perp_B y \iff \|x + \lambda y\| \geq \|x\| \) for all \( \lambda \).

DEFINITION 4 (James [4]). \( x \perp_J y \iff \|x + y\| = \|x - y\| \).

Interesting results concerning the characterization of inner product spaces through the assumption of additional properties of \( B \)-orthogonality (Definition 3) have been obtained by Birkhoff [1] and James [5], [6]. We continue this study in the following direction.

In an inner product space, if \( y \in [x_i]_{i=1}^n \) and \( y \perp x_i \) for all \( i \), then \( y = 0 \).

We show that this situation essentially characterizes inner product spaces with respect to both \( B \)-orthogonality and \( J \)-orthogonality.

THEOREM 5. \( E \) is an inner product space \( \iff \) whenever \( \{x_i\}_{i=1}^n \) is a linearly independent set of normalized vectors in \( E \) \((n \geq 3)\) and \( y \in [x_i]_{i=1}^n \) with \( y \perp_B x_i \) for all \( i \), then \( y = 0 \).

COROLLARY 1. \( E \) is an inner product space \( \iff \) given \( \{x_i\}_{i=1}^n \) a linearly independent normalized set in \( E \) \((n \geq 3)\) and \( \{x_i^*\}_{i=1}^n \subset E^* \) with \( \|x_i^*\| = 1 = (x_i^*, x_i) \) for all \( i \), then \( \det(\{x_i^*, x_j\}) \neq 0 \).

Note. If in Theorem 5 we restrict ourselves to sets of two vectors, another characterization of rotundity is obtained.

For the case of \( J \)-orthogonality we have

THEOREM 6. \( E \) is an inner product space \( \iff \) whenever \( \{x_i\}_{i=1}^n \) is a linearly
independent normalized set in \( E \) \((n \geq 2)\) and \( y \in [x_i]_{i=1}^n \) with \( y \perp \perp \sum_{i} x_i \) for all \( i \), then \( y = 0 \).

Finally we have two more straightforward characterizations.

**Theorem 7.** \( E \) is an inner product space \( \iff \) whenever \( \|x_1\| = \|x_2\| \), then \( x_1 + x_2 \perp \perp x_1 - x_2 \).

**Theorem 8.** \( E \) is an inner product space \( \iff \) whenever \( x \perp \perp y \) then \( x \perp \perp y \).

*Note.* In regard to Theorem 8, Day has shown that \( E \) is an inner product space \( \iff \) whenever \( x \perp \perp y \) then \( x \perp \perp y \) [3].
