A WEAK RAMANUJAN CONJECTURE FOR GENERIC
CUSPIDAL SPECTRUM OF QUASI-SPLIT GROUPS

FREYDOON SHAHIDI

The strong form of the Ramanujan conjecture for a quasi-split reductive
group had predicted that all the components of a cusp form are tempered
(cf. [5, 13]). But, examples of Kurokawa (cf. [11]) and Howe and Piatetski-
Shapiro [5] have shown that this is not true in general. In fact, even for PSP4
there are cusp forms which already defy the conjecture. Consequently, in [11]
Langlands predicted that an automorphic representation fails to be tempered
only if it lifts to an anomalous representation of some GL(n).

On a quasi-split group, one may consider the class of cusp forms which
as representations can be realized on spaces of functions which transform on
the left according to a generic character of the unipotent radical of a Borel
subgroup (i.e., the ones with Whittaker models). We call such automorphic
representations generic. None of the nontempered automorphic representa-
tions constructed so far are generic. In what follows, we shall produce some
evidence towards the validity of the strong Ramanujan conjecture for generic
automorphic forms (Theorems 1 and 2, and Corollary 2). In fact, in Corol-
lary 2, we obtain a uniform bound for the Hecke eigenvalues of generic cusp
forms on many absolutely simple quasi-split groups over number fields. It also
provides us with a new proof of the best available estimate for the Fourier
coefficients of Maass wave forms (Corollary 4). Detailed proofs will appear
elsewhere.

Let G be a quasi-split group over a number field F. Set G = G(AF). Let
P be a maximal F-parabolic subgroup of G. Write P = MN and let P, M,
and N be the corresponding groups of adelic points. Let v be a place of F and
denote by G_v, P_v, M_v, and N_v the corresponding local groups of F_v-rational
points. Let σ be a cusp form on M and write σ = ⊗_v σ_v, a restricted tensor
product of representations of the local groups G_v (cf. [3]).

Let $U$ be the unipotent radical of a Borel subgroup of $G$ such that $U \subseteq N$. A character $\chi = \bigotimes_v \chi_v$ of $U(\mathbb{A}_F)$ is called generic if, for every $v$, the restriction of $\chi_v$ to every root space in $U_v$ generated by a simple root is nontrivial. The representation $\sigma_v$ is then called $\chi_v$-generic, if it can be realized on a space of functions $W$ on $G_v$ satisfying

$$W(ug) = \chi_v(u)W(g) \quad (u \in U_v, \ g \in G_v).$$

We shall say $\sigma$ is $\chi$-generic if each $\sigma_v$ is $\chi_v$-generic (cf. [15], for example). Finally, we say $\sigma$ is generic, if it is generic with respect to some $\chi$.

Let $\alpha$ be the unique reduced $F$-root of the split component $A$ of the center of $M$ in $N$ and denote by $\rho_P$ half the sum of the $F$-roots generating $N$. Then $\hat{\alpha} = (\rho_P, \alpha)^{-1} \rho_P$ belongs to the complex dual of the real Lie algebra $\mathfrak{a}$ of $A$. Let $C$ be the field of complex numbers. We shall now identify $C$ with a subspace of the complex dual of $\mathfrak{a}$ by identifying $s \in C$ with $s\hat{\alpha}$. Then for each $v$, $s$ becomes an element in the complex dual of the real Lie algebra $\mathfrak{a}_v$ of the split torus in the center of $M$ as a group over $F_v$.

From [16], for every $v$ there exists a homomorphism $H_P_v$ from $M_v$ into $a_v$. Denote by

$$I(s, \sigma_v) = \text{Ind}_{G_v}^{G} \sigma_v \otimes q_v^{\{s, H_P_v(\cdot)\}},$$

the representation of $G_v$ induced from $\sigma_v$ and $s$, where $q_v$ is the cardinality of the residue class field of $F_v$.

Let $A(s, \sigma_v)$ be the standard intertwining operator attached to $I(s, \sigma_v)$ (cf. [15, 16]). Moreover, given a cuspidal form $\sigma$ on $M$, let $M(s, \sigma)$ be the constant term of the Eisenstein series defined by $\sigma$ (cf. [8]). Then $M(s, \sigma) = \bigotimes_v A(s, \sigma_v)$.

We use $S$ to denote a finite set of places of $F$, including the archimedean ones, such that for $v \notin S$, $G, \sigma_v$, and $\chi_v$ are all unramified (cf. [2]).

Let $L^M$ be the $L$-group of $M$ (cf. [2, 10]). It is a complex Lie group. Given a finite-dimensional complex representation $r$ of $L^M$, let $r_v$ be its restriction to $L^M_v$, the $L$-group of $M$ as a group over $F_v$.

For a finite place $v$ of $F$ with $v \notin S$, let $L(s, r_v, \sigma_v)$ be the Langlands $L$-function attached to $r_v$ and $\sigma_v$ (cf. [2, 10]). Here $s$ is a complex number. Then the Euler product

$$L_S(s, r, \sigma) = \prod_{v \notin S} L(s, r_v, \sigma_v)$$

always converges absolutely for $\text{Re}(s)$ large enough [10].

There exist $m$ finite-dimensional representations $r_1, \ldots, r_m$ of $L^M$ such that (cf. [9, 15])

$$M(s, \sigma)f = \bigotimes_{v \in S} A(s, \sigma_v) \tilde{f}_v \otimes \bigotimes_{v \notin S} f_v \cdot \prod_{i=1}^{m} L_S(is, \tilde{r}_i, \sigma)/L_S(1 + is, \tilde{r}_i, \sigma),$$

where $f = \bigotimes_v f_v$, $f_v \in I(s, \sigma_v)$, and for every $v \notin S$, $f_v$ is the $G(0_v)$-fixed function, normalized by $f_v(e_v) = 1$. Here $\tilde{r}_i$ is the contragredient of $r_i$. The representations $r_i$ are all irreducible. The significance of these $L$-functions is
that all the automorphic $L$-functions studied so far are among them. We then prove:

**Theorem 1.** Suppose $\sigma$ is generic and cuspidal.

(a) Assume $m = 1$. Then for $\Re(s) > 2$, the $L$-function $L_S(s, r_1, \sigma)$ is absolutely convergent.

(b) Suppose $m > 1$. Assume further that the restriction of $\sigma$ to the center of $M$ is trivial. Then for $\Re(s) > 2$, the $L$-functions $L_S(s, r_i, \sigma)$ are all absolutely convergent, $i = 1, \ldots, m$.

This is a consequence of the following result.

**Theorem 2.** Suppose $\sigma$ is cuspidal and generic.

(a) Assume $m = 1$. Then for each finite $v \in S$, $A(s, \sigma_v)$ is holomorphic for $\Re(s) \geq 1$.

(b) Suppose $m > 1$. Assume further that the restriction of $\sigma$ to the center of $M$ is trivial. Then for each finite $v \in S$, $A(s, \sigma_v)$ is holomorphic for $\Re(s) \geq 1$.

**Remark 1.** When $G = \text{GL}_{n+r}$, $M = \text{GL}_n \times \text{GL}_r$, $m = 1$, and Theorem 2 becomes Proposition 2.2 of [6], whose proof is based on a classification theorem for generic representations of $\text{GL}_n$ which is a fairly deep result of Bernstein and Zelevinski [1, 17] (cf. [7]), and certain properties of local Rankin-Selberg $L$-functions [7].

**Remark 2.** The assumption that $\sigma$ is trivial on the center of $M$ (when $ra > 1$) is made so that the necessary induction can be established in general (Lemma 1). However there are many cases with $m > 1$ for which the assumption is not necessary. This is due to our better understanding of $L_S(s, r_i, \sigma)$, $i = 2, \ldots, m$, in these special cases (cf. Corollary 2).

**Remark 3.** If $\sigma$ is trivial on the center of $M$, then Theorem 1 is still true if $M$ is replaced by its adjoint group $\overline{M}$, $\rho: M \to \overline{M}$, since then $\sigma$ may be extended to a representation $\overline{\sigma}$ of $\overline{M}(\mathbb{A}_F)$ satisfying

$$L_S(s, r_i, \sigma) = L_S(s, r_i, \rho, \overline{\sigma}),$$

$i = 1, \ldots, m$.

**Corollary 1.** Suppose $\sigma$ is cuspidal and generic.

(a) Assume $m = 1$. Then for $\Re(s) \geq 1$, the poles of the corresponding Eisenstein series depend only on the poles of $\bigotimes_{v=\infty} A(s, \sigma_v)$ and $L_S(s, \tilde{r}_1, \sigma)$.

(b) Suppose $m > 1$. Assume further that the restriction of $\sigma$ to the center of $M$ is trivial. Then for $\Re(s) \geq 1$, the poles of the corresponding Eisenstein series depend only on the poles of $\bigotimes_{v=\infty} A(s, \sigma_v)$ and $\prod_{i=1}^{2} L_S(is, \tilde{r}_1, \sigma)$. Moreover, for $\Re(s) > 1$, the dependence on the $L$-functions reduces to $L_S(s, \tilde{r}_1, \sigma)$.

**Corollary 2.** Let $G$ be either $\text{GL}(n)$, $U(n, n)$, $U(n + 1, n)$, $\text{SP}(2n)$, $\text{SO}(m, n)$, $m = n, n+1, n+2$, their groups of similitudes, their adjoint groups and those of split groups of types $E_6$ and $E_7$ over a number field $F$. Let $\sigma = \bigotimes_v \sigma_v$ be a $\chi$-generic cusp form on $G = G(\mathbb{A}_F)$. At each place $v$ of $F$ where $\sigma_v, \chi_v$, and $G$ are all unramified, let $t_v$ be the element in $k T^0$ representing
the corresponding semisimple conjugacy class in \( L_{G_v} \). Finally, let \( \mu \) be a weight for the restriction of the standard representation (first fundamental representation) of \( L_G \) to \( L_{G^0} \). Then \( |\mu(t_v)| < q_v \), where \( q_v \) is the cardinality of the residue class field of \( F_v \).

**Remark 1.** The strong Ramanujan Conjecture is equivalent to \( |\mu(t_v)| \leq 1 \).

**Remark 2.** When \( G = \text{GL}_n \), the proof of Theorem 2 (see Lemma 3 below) applied to \( \text{GL}_{2n} \) with Levi factor \( M = \text{GL}_n \times \text{GL}_n \) and representation \( \sigma \otimes \sigma \) of \( M \), will immediately imply that \( |\mu(t_v)| < q_v^{1/2} \). This is Corollary 2.5 of [7].

**Sketch of the proof of Theorem 2.** Under the assumption part (b), we may consider the \( L \)-functions as those for the adjoint group \( \overline{M} \) of \( M \). Let \( \rho: M \to \overline{M} \) be the corresponding projection.

In the following lemma we shall assume that \( G \) has neither a factor of type \( ^2A_{2k} \), nor a factor of type \( F_4 \), if the part of \( M \) in this factor is generated by \( \{\alpha_1, \alpha_2, \alpha_3, \alpha_4\} \) (\( \alpha_1 \) and \( \alpha_2 \) are long). In these two cases the necessary lemmas can be verified directly.

**Lemma 1.** Fix \( i, \ 2 \leq i \leq m \). There exist a quasi-split connected reductive \( F \)-group \( G_i \), unramified outside \( S \), a maximal \( F \)-parabolic subgroup with a Levi factor \( M_i \subset G_i \) whose adjoint group \( \overline{M}_i \) embeds into \( M \) by a \( F \)-rational map \( j: \overline{M}_i \to \overline{M} \) such that if \( r'_1, \ldots, r'_m \) are the corresponding representations of \( L_{M_i} \), then

\[
L_{\rho_i} = r'_1 \cdot L_{\rho_i} \cdot L_j,
\]

where \( \rho_i: M_i \to M \) is the natural projection. Moreover \( m_i < m \).

**Corollary 3** (of Lemma 1). Let \( \overline{M} \) be the adjoint group of \( M \). Fix a generic cusp form on \( \overline{M}(A_F) \). Then every \( L \)-function \( L_S(s, r_i, \sigma) \), \( i = 1, \ldots, m \), extends to a meromorphic function of \( s \) on \( \mathbb{C} \) satisfying a standard functional equation.

**Remark.** It is the subject of a forthcoming paper that for a large class of these partial \( L \)-functions, local factors at the ramified places can be defined in such a way that each resulting \( L \)-function extends to a meromorphic function of \( s \) with possibly only a finite number of poles in the entire complex plane. The factors at the archimedean places are the Artin factors defined by the Langlands’ local class field theory at such places.

Up to a finite number of factors (which can be made nonzero), every non-constant Fourier coefficient of the Eisenstein series (cf. [14, 15]) is equal to

\[
\prod_{i=1}^{m} L_S(1 + is, \tilde{r}_i, \sigma)^{-1},
\]

and consequently, for \( \Re(s) \geq 0 \),

\[
\prod_{i=1}^{m} L_S(1 + is, \tilde{r}_i, \sigma)
\]
has only a finite number of zeros which are all on the real axis. Now, by Lemma 1 and induction we in fact have:

**Lemma 2.** For Re(s) ≥ 1, $L_S(s, \tilde{r}_i, \sigma)$ and the quotient

$$L_S(s, \tilde{r}_i, \sigma)/L_S(1 + s, \tilde{r}_i, \sigma)$$

both have only a finite number of poles and zeros, $1 \leq i \leq m$.

**Proof of Theorem 2.** By Lemma 2 and relation (1), we conclude that except for a finite number of real poles, $M(s, \sigma)f$ and $\bigotimes_{v \in S} A(s, \sigma_v)f_v$ have the same poles when Re(s) ≥ 1. Fix $v \in S$, $v < \infty$. For every $w \in S$, $w \neq v$, $w < \infty$, we can choose $f_w$ such that $A(s, \sigma_w)f_w$ becomes a nonzero constant independent of s. Now, suppose for some s, with Re(s) ≥ 1, $A(s, \sigma_v)$ has a pole. For each such pole and each $w = \infty$, choose $f_w$ such that $A(s, \sigma_w)f_w \neq 0$. The operator $A(s, \sigma_v)$, being a rational function of $q_v^{-s}$, will then have infinitely many poles parallel to the imaginary axis. Consequently, $M(s, \sigma)f$ must also have infinitely many such poles. This is a contradiction to the finiteness of poles for $M(s, \sigma)$ when Re(s) ≥ 0.

To prove Theorem 1, we need the following lemma.

**Lemma 3.** Suppose v is unramified. Then for Re(s) ≥ 1, each $L(s, \tilde{r}_i, \sigma_v)$ is holomorphic, $1 \leq i \leq m$.

To conclude we shall now give a new proof of the following result (cf. [12] for the original proof; it is also due to Serre). It no longer requires the use of Rankin products; nor of Landau’s Lemma.

**Corollary 4.** Let $\pi$ be a nonmonomial cuspidal representation of $\text{PGL}_2(\mathbb{A}_F)$. At each unramified v, let $t_v = \text{diag}(\alpha_v, \alpha_v^{-1})$ be the corresponding semisimple conjugacy class in $\text{SL}_2(\mathbb{C})$. Then $q_v^{-1/5} < |\alpha_v| < q_v^{1/5}$.

**Proof.** We only need to apply Lemma 3 to a split group of type $F_4$ (example 4.1.6 of [15]) with $M$ generated by $\{\alpha_1, \alpha_2, \alpha_4\}$ ($\alpha_1$ and $\alpha_2$ are long), and $\sigma = \Pi \otimes \pi$, where $\Pi$ is the Gelbart-Jacquet [4] lift of $\pi$ to $\text{PGL}_2(\mathbb{A}_F)$.
