FORMAL ADJOINTS AND A CANONICAL FORM
FOR LINEAR OPERATORS

MICHAEL G. EASTWOOD AND A. ROD GOVER

Abstract. We describe a canonical form for linear differential operators that are formally self-adjoint or formally skew-adjoint.

Suppose $E$ and $F$ are smooth vector bundles on an oriented smooth manifold $M$. Let $\text{vol}$ denote the bundle of volume forms on $M$. The formal adjoint of a linear differential operator $L : E \to F$ is the differential operator $L^* : F^* \otimes \text{vol} \to E^* \otimes \text{vol}$ characterised by the equation

$$\int_M \langle L^* \sigma, \tau \rangle = \int_M \langle \sigma, L \tau \rangle \quad \text{for } \sigma \in \Gamma(M, F^* \otimes \text{vol}) \text{ and } \tau \in \Gamma_*(M, E).$$

Here all sections are assumed sufficiently smooth and $\Gamma_*$ indicates the space of compactly supported sections. If $F = E^* \otimes \text{vol}$, then $L^* : E \to F$ and there is a canonical decomposition

$$L = L_+ + L_- = 1/2[L + L^*] + 1/2[L - L^*]$$

into self-adjoint and skew-adjoint parts. Henceforth let us assume that $M$ is equipped with a preferred volume form and a compatible torsion-free connection $\nabla$ (e.g. $M$ is Riemannian).

Suppose that $E$ is trivial. Then the preferred volume form trivialises $F$, and so $L$ may be viewed as taking functions to functions and written in terms of the given connection. A formula for its adjoint is determined by integration by parts. Suppose, for example, that $L$ is second order. Then we may write

$$L = S^{ab} \nabla_a \nabla_b + T^b \nabla_b + R,$$

where the tensor $S^{ab}$ is symmetric. Adopting the convention that $\nabla_a$ acts on everything to its right, we can re-express $L$ in the form

$$L = \nabla_a S^{ab} \nabla_b + (\tilde{T}^b \nabla_b + \nabla_b \tilde{T}^b) + \tilde{R}$$

where the tensor $\tilde{T}$ and scalar field $\tilde{R}$ are given by $\tilde{T}^b = 1/2(T^b - (\nabla_a S^{ab}))$ and $\tilde{R} = R - (\nabla_b \tilde{T}^b)$. This is congenial since clearly

$$L^* = \nabla_a S^{ab} \nabla_b - (\tilde{T}^b \nabla_b + \nabla_b \tilde{T}^b) + \tilde{R}.$$
In particular,
\[ L_+ = \nabla_a S^{ab} \nabla_b \tilde{R} \quad \text{and} \quad L_- = \tilde{T}^b \nabla_b + \nabla_b \tilde{T}^b. \]

By an obvious inductive argument this generalises immediately to give the following result.

**Theorem 1.** A self-adjoint \( k \)th order linear differential operator taking functions to functions on \( M \) has even order and may be canonically written in the form:

\[
\sum_{i=0}^{k/2} \nabla_a \cdots \nabla_b S_{\Psi \Phi}^{a \cdots d} \nabla_c \cdots \nabla_d,
\]

for suitable symmetric tensors \( S_{\Psi \Phi}^{a \cdots d} \). A skew-adjoint \( k \)th order linear differential operator taking functions to functions on \( M \) has odd order and may be canonically written in the form:

\[
\sum_{i=0}^{(k-1)/2} \nabla_a \cdots \nabla_b (\nabla_c A_{\Psi \Phi}^{a \cdots b c d \cdots e} + A_{\Psi \Phi}^{a \cdots b c d \cdots e} \nabla_c) \nabla_d \cdots \nabla_e,
\]

for suitable symmetric tensors \( A_{\Psi \Phi}^{a \cdots e} \).

Suppose now that \( E \) is a vector bundle (possibly a tensor bundle) with connection on \( M \) and write \( \nabla \) to indicate the coupled tensor-vector bundle connection. Let us use upper case Greek indices as abstract indices for the bundle \( E \) and its dual. Then, for example, operators \( L : E \to E^\ast \) may be written \( L_{\Psi \Phi} : E^\Phi \to E^\Psi \). Since the tensor product \( E^\ast \otimes E^\ast \) decomposes canonically into symmetric and skew-symmetric parts, it follows easily that the above generalises as follows. We write \([\ell]\) to indicate the integer part of a real number \( \ell \).

**Theorem 2.** A self-adjoint (respectively skew-adjoint) \( k \)th order linear differential operator \( L_{\Psi \Phi} : E^\Phi \to E^\Psi \) on \( M \) may be canonically written in the form:

\[
\sum_{i=0}^{[k/2]} \nabla_a \cdots \nabla_b S_{\Psi \Phi}^{a \cdots b c d \cdots d} \nabla_c \cdots \nabla_d \\
+ \sum_{i=0}^{[(k-1)/2]} \nabla_a \cdots \nabla_b (\nabla_c A_{\Psi \Phi}^{a \cdots b c d \cdots e} + A_{\Psi \Phi}^{a \cdots b c d \cdots e} \nabla_c) \nabla_d \cdots \nabla_e,
\]

where the sections \( S_{\Psi \Phi}^{a \cdots d} \) are symmetric over the tensor indices and symmetric (respectively skew-symmetric) over the pair \( \Psi \Phi \) of vector bundle indices; the sections \( A_{\Psi \Phi}^{a \cdots e} \) are symmetric over the tensor indices and skew-symmetric (respectively symmetric) over the pair \( \Psi \Phi \) of vector bundle indices.

Here is an example application. Suppose that \( P \) is a self-adjoint linear differential operator \( P \) of order \( k > 0 \) that takes functions to functions on \( M \). Write \( \tilde{P} \) for the modified operator obtained by subtracting from \( P \) the scalar part obtained by applying \( P \) to \( f \equiv 1 \). Then \( \tilde{P} \) is formally self-adjoint and takes the form \( f \mapsto \nabla_a (Q^{ab} \nabla_b f) \) for a suitable differential operator \( Q : T^\ast M \to TM \). Since the construction of \( \tilde{P} \) is canonical, \( \tilde{P} \) enjoys the same naturalness and/or invariance properties as does \( P \).

A good example arises in conformal geometry. Suppose \( M \) is an oriented conformal manifold of even dimension \( 2m \). Let \( L \) denote any conformally invariant
operator on functions that, with respect to any Riemannian metric in the conformal class, takes the form
\[ L = \Delta^m + \text{lower order terms}. \]

Since \( L \) takes functions to volume forms, so does its formal adjoint. The self-adjoint part \( L^+ \) of \( L \) is therefore also conformally invariant. As a conformal analogue of \( \Delta^m \) (in the sense of [3]), we may as well replace \( L \) by \( L^+ \). Then by Theorem 1 this, in turn, may be replaced by a self-adjoint conformally invariant modification of the form \( f \mapsto \nabla_a (Q^{ab}(\nabla_b f)) \) for a suitable \((n-2)\text{nd order differential operator} \) \( Q : \Lambda^1 \to \Lambda^{n-1} \). Thus, we obtain the following result conjectured to us by Tom Branson.

**Theorem 3.** Any conformally invariant linear differential operator of the form (1) admits a self-adjoint conformally invariant modification of the form \( f \mapsto \nabla_a (Q^{ab}(\nabla_b f)) \) for a suitable \((n-2)\text{nd linear order differential operator} \) \( Q : \Lambda^1 \to \Lambda^{n-1} \).

The motivation for Branson’s conjecture came from the case of the sphere where the form of the operator may be verified directly. On the sphere, the operator controls the embedding \( L^2_m \hookrightarrow e^L \) (Orlitz class) as a limiting case of the sharp Sobolev embeddings \( L^2_r \hookrightarrow L^{2n/r} \) for \( r < n/2 \) (equivalently, comparing an \( L^q \) norm with the complementary series norm); see [1] for further discussion. In [4], Graham, Jenne, Mason, and Sparling established the existence of operators of the form (1). More recently it has been shown, using scattering theory [5] (and alternatively via the Fefferman–Graham ambient metric [2]) that the particular operators constructed in [4] are, in fact, already formally self-adjoint and have the form given in Theorem 3.
