RANDOM POLYNOMIALS HAVING FEW OR NO REAL ZEROS

AMIR DEMBO, BJORN POONEN, QI-MAN SHAO, AND OFER ZEITOUNI

1. Introduction

Let \( \{a_i\}_{i=0}^{\infty} \) denote a sequence of independent, identically distributed (i.i.d.) random variables of zero mean and unit variance. Consider the random polynomial

\[
f_n(x) = \sum_{i=0}^{n-1} a_i x^i.
\]

For \( n \) odd, define

\[
P_n = P(f_n(x) > 0 \ \forall x \in \mathbb{R}).
\]

As described in Section 1.1, the study of the number of zeros of random polynomials has a long history. Our main goal is to prove that

\[
P_n = n^{-b+o(1)} \quad \text{as} \quad n \to \infty
\]

for a finite constant \( b > 0 \), at least when the coefficient distribution has finite moments of all orders. The constant \( b \) can be described in terms of the centered stationary Gaussian process \( Y_t \) with correlation function \( R_y(t) = \text{sech}(t/2) \) (see (1.4) for an explicit construction of \( Y \)). Define

\[
b = -4 \lim_{T \to \infty} \frac{1}{T} \log P\left( \sup_{0 \leq t \leq T} Y_t \leq 0 \right),
\]

where, throughout this paper, \( \log \) denotes the natural logarithm. The existence of the limit in (1.3) and the estimate \( b \in [0.4, 2] \) are proved in Lemma 2.5. We note in passing that our numerical simulations of random polynomials of degree \( n \leq 1024 \) suggest \( b = 0.76 \pm 0.03 \).

Our main result, which is a consequence of Theorem 1.3 stated in Section 1.2, is the following

**Theorem 1.1.** a) Suppose \( \{a_i\} \) is a sequence of zero-mean, unit-variance, i.i.d. random variables possessing finite moments of all orders. Then,

\[
\lim_{n \to \infty} \frac{\log P_{2n+1}}{\log n} = -b.
\]
b) If \( \{a_i\} \) is as above but with \( E(a_i) = \mu \neq 0 \), we denote \( P_n^a = P(f_n(x) \neq 0 \ \forall x \in \mathbb{R}) \). Then,

\[
\lim_{n \to \infty} \frac{\log P_{2n+1}^\mu}{\log n} = -b/2.
\]

It is interesting to note that one may answer questions related to a prescribed number of zeros. Our main result in this direction is the following theorem. For a slightly different variant, allowing to prescribe the location of zeros, see also Proposition 1.5.

**Theorem 1.2.** Under the assumptions of Theorem 1.1a, the probability that the random polynomial \( f_{n+1}(x) \) of degree \( n \) has \( o(\log n/\log \log n) \) real zeros is \( n^{-b+o(1)} \) as \( n \to \infty \). For any fixed \( k \), the probability \( p_{n,k} \) that \( f_{n+1} \) has exactly \( k \) real zeros, all of which are simple, satisfies

\[
\lim_{n \to \infty} \frac{\log p_{2n+k,k}}{\log n} = -b.
\]

(Obviously, \( p_{n,k} = 0 \) when \( n - k \) is odd.)

The key to our analysis is a detailed study of the case where the coefficients are Gaussian, implying that \( f_n(\cdot) \) is a Gaussian process (Gaussian processes are particularly useful in this context because for them comparisons can be made via Slepian’s lemma). The extension to general distribution uses the strong approximation results of Komlós-Major-Tusnády [KMT]. Although this technique requires finite moments of all order, we conjecture that the asymptotic \( n^{-b+o(1)} \) applies to \( p_{n,k} \) for \( n - k \) even, whenever the nondegenerate zero-mean i.i.d. \( a_i \) are in the domain of attraction of the Normal distribution. This conjecture is supported by the following heuristic derivation of \( P_n = n^{-b+o(1)} \).

For \( x \in [0, 1] \) near 1, let \( x = 1 - e^{-t} \). Note that \( x^t \approx \exp(-e^{-t}) \) when \( t \gg 0 \), and moreover, the function \( h_t(u) := \exp(-e^{-t}u^2) \) changes slowly in \( u \) for \( t \gg 0 \). Summation by parts suggests that the sign of \( f_n(x) \) is mostly determined by the behavior of \( \sum_{j=0} a_i \) for large \( j \) depending on \( t \). Hence, for \( a_i \) in the domain of attraction of the Normal distribution, we next replace \( a_i \) with i.i.d. standard Normal variables \( b_i \). Using the representation \( b_t = W_{i+1} - W_i \) for a standard Brownian motion \( W_t \) we further replace the sum over \( i = 0, \ldots, n - 1 \) with the corresponding stochastic integral over \( [0, \infty) \). This in turn yields the approximation of the normalized \( \hat{f}_n(x) := f_n(x)/\sqrt{\text{Var}(f_n(x))} \) by the centered, Gaussian process

\[
Y_t = \frac{\int_0^\infty h_t(u) dW_u}{(\int_0^\infty h_t(u)^2 du)^{1/2}}.
\]

It is easy to check that the process \( Y \) of (1.4) is stationary, with correlation function \( \text{sech}(t/2) \). By continuity arguments, \( f_n(x) \) typically has a constant sign in \([1 - n^{-1}, 1]\), so our approximation procedure is relevant only as long as \( t \leq \log n \). Alternatively, \( t = \log n \) is where we start seeing \( h_t(n) = O(1) \), contrasting the replacement of the upper limit \( n \) in the discrete sum with the upper limit \( \infty \) in the stochastic integral of (1.4). We are to consider the possibility of \( f_n(x) = 0 \) for \( x \) in the left and in the right neighborhoods of both \(-1\) and \( +1 \). In each of these four regimes of \( x \) the function \( f_n(x) \) is amenable to a similar treatment, leading to an approximation by the process \( Y_t \). With \( \hat{f}_n \) having approximately independent values in the four different regimes, we arrive at the formula (1.3) for \( b \).
It is natural to wonder what happens when \( a_i \) are of a symmetric law that is in the domain of attraction of an \( \alpha \)-stable law, for some \( \alpha \in (0, 2) \). A lower bound on \( P_n \) of the form \( n^{-c} \) for some finite value of \( c \) is then easily obtained by considering the event that \( a_0 \) and \( a_{n-1} \) are “huge” and positive, while other coefficients are “reasonable”. Repeating the above heuristic for this case, one is led to believe that the formula (1.3) still applies, but now with \( Y_1 \) of (1.4) replaced by

\[
Y_{t, \alpha} = \int_0^\infty h_t(u)dX_{u}^{(\alpha)}
\]

where \( X_{u}^{(\alpha)} \) denotes the symmetric stable process of index \( \alpha \) and the stochastic integral in (1.5) is to be interpreted via integration by parts. We have yet no strong evidence to support the above statement. However, our numerical simulations indicate the behavior \( P_n = n^{-b_1+o(1)} \) for i.i.d. Cauchy random variables \( a_i \) (that is, \( \alpha = 1 \)), where \( b_1 \approx 0.86 \) is larger than \( b \).

1.1. Historical remarks. Throughout this section, \( \{a_i\} \) are independent, identically distributed, nondegenerate, real-valued random variables\(^{[1]}\). Let \( N_n \) denote the number of distinct real zeros of \( f(x) := \sum_{i=0}^n a_i x^i \). (For the sake of definiteness, we define \( N_n = 0 \) when \( f \) is the zero polynomial.) So, \( p_n := P(N_n = 0) = p_{n,0} \) and we also let \( E_n \) and \( V_n \) denote the mean and variance of \( N_n \).

The study of real zeros of random polynomials has a long and full history, but most often deals with the asymptotic behavior of \( E_n \) instead of \( p_n \). Presumably this is because \( E_n \) is much easier to estimate: because expectation is linear, one can compute \( E_n \) by integrating over the real line the probability of having a root in \((t, t + dt)\), for example.

Although as mentioned in [To, p. 618], one can find probabilistic statements in the context of zeros of polynomials as early as 1782 (Waring) and 1864 (Sylvester), the first people to study the asymptotic behavior of \( N_n \) seem to be Bloch and Pólya [BP]. In 1932, they proved \( E_n = O(n^{1/2}) \) for the coefficient distribution \( P(a_i = 1) = P(a_i = 0) = P(a_i = -1) = 1/3 \). This work led Littlewood and Offord to undertake a systematic study of \( N_n \) in a series of papers [LO1, LO2, LO3] starting in 1938. They proved that if the \( a_i \) are all uniform on \([-1, 1] \), or all Normal, or all uniform on \([-1, 1] \) (i.e. \( P(a_i = 1) = P(a_i = -1) = 1/2 \)), then

\[
P\left(N_n > 25(\log n)^2\right) \leq \frac{12 \log n}{n} \quad \text{and} \quad P\left(N_n < \frac{\alpha \log n}{(\log \log n)^2}\right) < \frac{A}{\log n}
\]

for some constants \( \alpha \) and \( A \). In particular, for some constant \( \alpha' \),

\[
\frac{\alpha' \log n}{(\log \log n)^2} \leq E_n \leq 25(\log n)^2 + 12 \log n
\]

and \( p_n = O(1/\log n) \) for these distributions. This upper bound for \( p_n \) has apparently not been improved, until the current paper\(^{[2]}\).

\[\text{\footnotesize Footnote:} \]

1. Some authors whose work we mention assumed \( a_0 = 1 \) or \( a_n = 1 \), but as far as asymptotic behavior as \( n \to \infty \) is concerned, it makes little difference.

2. The asymptotic behavior does not depend on whether roots are counted with multiplicity or not.

3. The only result in the literature that might be said to have improved our knowledge of \( p_n \) is [LE], which together with [LO2] implies for many distributions that \( \limsup_{n \to \infty} p_n \log n \leq \pi - 2 \). The bound has the same form as that arising from the work of Littlewood and Offord, but the constant has been made explicit.
In 1943 Kac \cite{Ka1} found the exact formula
\begin{equation}
E_n = \frac{1}{\pi} \int_{-\infty}^{\infty} \sqrt{\frac{1}{(t^2 - 1)^2} - \frac{(n+1)^2 t^{2n}}{(t^{2n} + 1)^2}} dt,
\end{equation}
when \( a_i \) is Normal with mean zero, and extracted from it the asymptotic estimate
\begin{equation}
E_n \sim \frac{2}{\pi} \log n.
\end{equation}

Much later Jamrom \cite{Ja} and Wang \cite{Wa} improved this to
\begin{equation}
E_n = \frac{2}{\pi} \log n + C + o(1)
\end{equation}
for an explicit constant \( C \), and ultimately Wilkins \cite{Wi} obtained an asymptotic series for \( E_n \) from (1.6). In 1949 Kac \cite{Ka2} obtained (1.7) for the case where \( a_i \) is uniform on \([-1, 1]\). Erdős and Offord \cite{EO} obtained the same asymptotic for \( a_i \) uniform on \([-1, 1]\). Stevens \cite{St} proved (1.7) for a wide class of distributions, and this estimate was finally extended by Ibragimov and Maslova \cite{IM1}, \cite{IM2} to all mean-zero distributions in the domain of attraction of the Normal law.

At around the same time (the late 1960’s), Logan and Shepp \cite{LS1}, \cite{LS2} discovered that if the coefficient distribution is the symmetric stable distribution with characteristic function \( \exp(-|z|^\alpha) \), \( 0 < \alpha \leq 2 \), then
\begin{equation}
E_n \sim c_\alpha \log n,
\end{equation}
where
\begin{equation}
c_\alpha := \frac{4}{\pi^2 \alpha^2} \int_{-\infty}^{\infty} dx \log \int_{-\infty}^{\infty} \frac{|x-y|^{\alpha} e^{-y}}{|x-1|^{\alpha}} dy > \frac{2}{\pi}.
\end{equation}

They also proved \( \lim_{\alpha \to 0^+} c_\alpha = 1 \), and performed calculations that suggested that \( c_\alpha \) is a decreasing function of \( \alpha \), terminating at \( c_2 = 2/\pi \), Kac’s value for the Normal distribution. Ibragimov and Maslova \cite{IM1} extended these results by finding the asymptotic behavior of \( E_n \) for arbitrary distributions in the domain of attraction of a stable distribution. The asymptotic is different when the distribution has nonzero mean; for instance \cite{IM3}, if \( a_i \) are Normal with nonzero mean, then \( E_n \sim (1/\pi) \log n \) instead of \( (2/\pi) \log n \). Shepp (private communication) has conjectured that there exists a universal constant \( B \) such that
\begin{equation}
\limsup_{n \to \infty} \frac{E_n}{\log n} \leq B
\end{equation}
for \textit{any} coefficient distribution (satisfying only the hypotheses at the beginning of this section). If \( B \) exists, then \( B \geq 1 \) by the work of Logan and Shepp mentioned above.

In 1974, Maslova \cite{Ma1}, \cite{Ma2} proved that if \( P(a_i = 0) = 0 \), \( Ea_i = 0 \) and \( E(a_i^{2+\epsilon}) < \infty \) for some \( \epsilon > 0 \), then
\begin{equation}
V_n \sim \frac{4}{\pi} \left( 1 - \frac{2}{\pi} \right) \log n
\end{equation}
and \( N_n \) is asymptotically Normal.

Much work was also done on complex roots of \( f_n(z) = 0 \); see \cite{IZ} and references therein for an updated account. Further results on random polynomials and their generalizations can be found in the books \cite{BR}, \cite{Fa} and the survey article \cite{EK}.

Our interest in the asymptotic of \( p_n \) grew out of a problem in arithmetic geometry. The paper \cite{PS} showed that Jacobians of curves over \( \mathbb{Q} \) could be odd, in the sense of having Shafarevich-Tate groups of nonsquare order (despite prior claims in the literature that this was impossible). Moreover it was shown (in a sense that was made precise) that the probability that a random hyper-elliptic curve \( y^2 = f(x) \) of
genus $g$ over $\mathbb{Q}$ has odd Jacobian could be related to a sequence of “local” probabilities, one for each nontrivial absolute value on $\mathbb{Q}$. The computation of the local probability for the standard archimedean absolute value reduced to the knowledge of the probability that the curve $y^2 = f(x)$ has no real point, or equivalently, the probability that the random polynomial $f(x)$ satisfies $f(x) < 0$ for all real $x$. Although the asymptotic behavior of this probability was not needed in a substantial way in [PS], the authors of that paper found the question to be of sufficient interest in its own right that they developed heuristics that led them to conjecture the existence of a universal constant $b > 0$ such that $p_n = n^{-b+o(1)}$, for any mean-zero distribution in the domain of attraction of the Normal law.

1.2. Statement of main theorems. Let $\hat{f}_n(x) := f_n(x)/\sqrt{E(f_n(x)^2)}$ denote the normalized random polynomial, so $\hat{f}_n(x)$ has unit variance for each $x$. Instead of proving only $P_n = n^{-b+o(1)}$, we generalize in the following, to facilitate applications to related problems.

Theorem 1.3. Suppose $a_i$ are zero-mean i.i.d. random variables of unit variance and with finite moments of all orders. For $n - 1$ even, let

$$P_{n, \gamma_n} = P \left( \hat{f}_n(x) > \gamma_n(x) \quad \forall x \in \mathbb{R} \right),$$

for nonrandom functions $\gamma_n(x)$ such that $n^b|\gamma_n(x)| \to 0$ uniformly in $x \in \mathbb{R}$ for some $\delta > 0$. Then,

$$\frac{\log P_{n, \gamma_n}}{\log n} \to -b. \quad (1.9)$$

The upper bound $P_{n, \gamma_n} \leq n^{-b+o(1)}$ applies as soon as

$$\inf \{ \gamma_n(x) : ||x| - 1| \leq n^{-\varepsilon_n} \} \to 0 \quad \text{for any } \varepsilon_n \to 0.$$

The key to the proof of Theorem 1.3 is the analysis of $P_{n, \gamma_n}$ for random polynomials $f_n(x)$ with coefficients $\{b_i\}$ that are i.i.d. standard Normal variables. To distinguish this case, we use throughout the notations $\hat{f}_n^b(x)$, $\hat{f}_n^0$ and $P_{n, \gamma_n}^b$ for $f_n(x)$, $\hat{f}_n(x)$ and $P_{n, \gamma_n}$, respectively, when dealing with polynomials of coefficients that are Normal variables. The next theorem summarizes our results in this special case.

Theorem 1.4. The convergence of $\log P_{n, \gamma_n}^b/\log n$ to $-b$ applies in the standard Normal case, as soon as the nonrandom functions $\gamma_n(x) \leq M < \infty$ are such that

$$\sup \{ |\gamma_n(x)| : ||x| - 1| \leq n^{-\varepsilon_n} \} \to 0 \quad \text{for some } \varepsilon_n \to 0.$$

The following proposition is the variant of Theorem 1.2 alluded to above. It shows that with probability $n^{-b+o(1)}$ one may also prescribe arbitrarily the location of the $k$ real zeros of $f_{n+1}(x)$, provided the support of the law of $a_i$ contains an open interval around 0. The latter assumption is to some extent necessary. For example, when $P(a_i = 1) = P(a_i = -1) = 1/2$ it is easy to see that $f_{n+1}(x)$ cannot have zeros in $[-1/2, 1/2]$.

Proposition 1.5. Suppose $a_i$ are zero-mean i.i.d. random variables of unit variance, finite moments of all orders, and the support of the law of each $a_i$ contains the interval $(-\eta, \eta)$ for some $\eta > 0$. Given disjoint open intervals $U_1, \ldots, U_k$ and positive integers $m_1, \ldots, m_k$, the probability that the random polynomial $f_{n+1}(x)$ has exactly $m_i$ real zeros in $U_i$ for each $i$ and no real zeros anywhere else is $n^{-b+o(1)}$ for $n \to \infty$ through integers of the same parity as $k = \sum_i m_i$. 
The organization of this paper is as follows. Auxiliary lemmas about Gaussian processes, needed for the proof of Theorem 1.4, are grouped in Section 2 including the bounds on $b$ mentioned in the introduction; cf. Lemma 2.5. Relying upon Gaussian techniques, the proof of the lower bound of Theorem 1.4 is in Section 3, and the complementary upper bound in Section 4. Building upon Theorem 1.4 and with the help of strong approximation, Section 5 provides the proof of our main result, Theorem 1.3. Theorem 1.1 is then derived in Section 6. Section 7 provides the upper bound on the probability of interest in Theorem 1.2, with the lower bound proved in Section 8. Finally, Proposition 1.5 is proved in Section 9.

2. Auxiliary lemmas

We start by introducing several notations that appear throughout this work. For $n$ odd, let $c_n(x, y)$ denote the covariance function of $\hat{f}_n(x)$, that is,

$$c_n(x, y) = \frac{E(f_n(x)f_n(y))}{\sqrt{E(f_n(x)^2)E(f_n(y)^2)}}.$$  

Then, for $x \neq \pm 1$ and $y \neq \pm 1$,

$$c_n(x, y) = g(x^n, y^n),$$  

where

$$g(x, y) = \frac{|xy - 1|}{\sqrt{|(1 - x^2)(1 - y^2)|}} \geq 0.$$  

Note that $g(x, y) = g(-x, -y) = g(\frac{1}{x}, \frac{1}{y})$. Further,

$$\forall x, y \in (-1, 1), \quad g(x, y) \geq 1$$

and the change of variables $z = 1 - x, w = 1 - y$ leads to

$$1 \quad g(x, y) = 2\sqrt{zw} \left[1 - \left[1 - \frac{wz}{z+w} - \sqrt{1 - \frac{wz}{z+w}} \sqrt{1 - \frac{wz}{z+w}}\right]\right].$$

A good control on $g(x, y)$ is provided by the following lemma.

**Lemma 2.1.** For any $z, w \in (0, 1/2]$,

$$\frac{1}{8}(w - z)^2 \leq \left(1 - \frac{wz}{w+z} - \sqrt{1 - \frac{z}{2}} \sqrt{1 - \frac{w}{2}}\right) \frac{\max(z, w)}{1 - \frac{wz}{w+z}} \leq (w - z)^2.$$

**Proof.** Let $z + w = \eta, z - w = \xi$, assuming without loss of generality that $0 < \xi \leq \eta \leq 1$. Since

$$1 \geq 1 - \frac{wz}{w+z} \geq \frac{1}{2}, \quad 1 \geq \frac{\max(z, w)}{z+w} \geq \frac{1}{2},$$

it suffices to prove that

$$f(w, z) = \frac{1}{(z-w)^2} \left[1 - \frac{wz}{w+z} - \sqrt{1 - \frac{z}{2}} \sqrt{1 - \frac{w}{2}}\right] (z + w) \in [1/4, 1/2].$$
To this end, observe that for all $0 < \xi \leq \eta \leq 1$ we have

$$f(w, z) = \frac{\eta}{\xi^2} \left[ 1 - \frac{\eta^2}{4\eta} - \sqrt{\left(1 - \frac{\eta}{4}\right)^2 - \left(\frac{\xi}{4}\right)^2} \right]$$

$$= \frac{\eta}{\xi^2} \left[ 1 - \frac{\eta}{4} + \frac{\xi^2}{4\eta} - \sqrt{\left(1 - \frac{\eta}{4}\right)^2 - \left(\frac{\xi}{4}\right)^2} \right] = \frac{1}{4} + \frac{\eta}{4\xi^2} \left[ 1 - \sqrt{1 - \frac{\xi^2}{4}} \right],$$

where $\tilde{\xi} = \xi/(4 - \eta)$, $\tilde{\eta} = (4 - \eta).$ Since $\xi \leq \eta \leq 4 - \eta$ and $0 \leq 1 - \sqrt{1 - \tilde{\xi}^2} \leq \tilde{\xi}^2$, it follows that $1/4 \leq f(w, z) \leq 1/4 + \tilde{\eta}/4 \leq 1/2$ as needed.

The control of Lemma 2.1 on $g(x, y)$, hence on $c_n(x, y)$, shall give rise to the perturbed centered Gaussian processes $Y^{(\alpha)}$ of the next lemma.

**Lemma 2.2.** Let $\alpha \in [0, 1]$ and define the covariance

$$R^{(\alpha)}(\tau) = \text{sech} \left( \frac{\tau}{2} \right) \left\{ 1 - \alpha (1 - e^{-|\tau|})^2 \right\}.$$

Then there exist independent, stationary centered Gaussian processes $Y_t, Z_t$, with covariances $R_y(\tau) = R^{(0)}(\tau)$ and

$$R_z(\tau) = R^{(1)}(\tau) = \text{sech} \left( \frac{\tau}{2} \right) \left( 2e^{-|\tau|} - e^{-2|\tau|} \right),$$

respectively, such that the process $Y_t^{(\alpha)} := \sqrt{1 - \alpha} Y_t + \sqrt{\alpha} Z_t$ has covariance $R^{(\alpha)}(\tau)$.

**Proof.** Since $R^{(\alpha)}(\tau) = (1 - \alpha)R_y(\tau) + \alpha R_z(\tau)$, all one needs is to check that both $R_y(\tau)$ and $R_z(\tau)$ are covariance functions, i.e. to check that their Fourier transforms are nonnegative. To this end, note that

$$S_y(\omega) := \mathcal{F}(R_y(\tau)) = \int_{-\infty}^{\infty} e^{i\omega \tau} R_y(\tau) d\tau$$

$$= 2 \int_0^{\infty} \cos(\omega \tau) \text{sech}(\frac{\tau}{2}) d\tau = 2\pi \text{sech}(\omega) \geq 0;$$

cf. [GR, p. 503, formula 3.981.3]. Furthermore,

$$S_z(\omega) := \mathcal{F}(R_z(\tau)) = \int_{-\infty}^{\infty} e^{i\omega \tau} R_z(\tau) d\tau = S_y(\omega) * F(\omega),$$

where $*$ stands throughout for the convolution operation and

$$F(\omega) = \int_{-\infty}^{\infty} e^{i\omega \tau} \left( 2e^{-|\tau|} - e^{-2|\tau|} \right) d\tau = 2 \int_0^{\infty} \cos(\omega \tau) \left( 2e^{-\tau} - e^{-2\tau} \right) d\tau$$

$$= \frac{4}{1 + \omega^2} - \frac{4}{4 + \omega^2} = \frac{12}{(4 + \omega^2)(1 + \omega^2)} \geq 0.$$

Hence, $S_z(\omega) \geq 0.$

The effect of nonrandom functions $\gamma_n(x)$ as well as that of considering the processes $Y^{(\alpha)}$ for some $\alpha_n \downarrow 0$ are dealt with by the continuity properties of $Y_t$ and $Z_t$ outlined in the next lemma.
Lemma 2.3. Let $Y_t, Z_t$ be as in Lemma 2.2. Then, for any positive $\varepsilon_T \to 0$,

$$\lim_{T \to \infty} P\left( \sup_{0 \leq t \leq T} Z_t \leq \sqrt{\varepsilon_T^{-1} \log T} \right) = 1,$$

whereas

$$\lim_{T \to \infty} \frac{1}{T} \log P\left( \sup_{0 \leq t \leq T} Y_t \leq \varepsilon_T \right) = \liminf_{T \to \infty} \frac{1}{T} \log P\left( \sup_{0 \leq t \leq T} Y_t \leq -\varepsilon_T \right) \leq \liminf_{T \to \infty} \frac{1}{T} \log P\left( \sup_{0 \leq t \leq T} Y_t \leq 0 \right) = \frac{b}{4}.$$

Moreover, for any positive $\gamma_T \to 0$ and $\alpha_T \log T \to 0$,

$$\liminf_{T \to \infty} \frac{1}{T} \log P\left( \inf_{0 \leq t \leq T} Y_t^{(\alpha_T)} \geq \gamma_T \right) \geq -\frac{b}{4}.$$

Proof. The existence of the limit in the right hand side of (2.5) (and hence in (1.3)) is ensured by sub-additivity: since $R_y(\cdot) > 0$, Slepian’s lemma (cf. [Ad], p. 49) and the stationarity of $Y$ imply

$$P\left( \sup_{0 \leq t \leq T+S} Y_t \leq 0 \right) \geq P\left( \sup_{0 \leq t \leq T} Y_t \leq 0 \right) P\left( \sup_{T \leq t \leq T+S} Y_t \leq 0 \right) = P\left( \sup_{0 \leq t \leq T} Y_t \leq 0 \right) P\left( \sup_{0 \leq t \leq S} Y_t \leq 0 \right).$$

Fix $\varepsilon_T \to 0$. From Lemma 2.2 we have that

$$S_z(\omega) = \mathcal{F}(R_z(\tau)) = 2\pi \text{sech}(\omega \pi) \frac{12}{(4 + \omega^2)(1 + \omega^2)},$$

which implies that $\sup_\omega \{ S_z(\omega) \omega^4 \} < \infty$. Hence $\int_{-\infty}^{\infty} \omega^2 S_z(\omega) d\omega < \infty$. It follows that

$$-\frac{\partial^2}{\partial \tau^2} R_z(\tau) \bigg|_{\tau = 0} = E(\dot{Z}_t^2) < \infty.$$

Since $|Z_t| \leq |Z_0| + \int_0^1 |\dot{Z}_t| dt$, it follows by stationarity of the centered Gaussian process $\dot{Z}_t$ that

$$m_1 := E\left( \sup_{0 \leq t \leq 1} |Z_t| \right) \leq \sqrt{E(Z_0^2)} + \sqrt{E(\dot{Z}_t^2)} < \infty.$$

By the stationarity of $Z_t$ and Borell’s inequality (cf. [Ad], p. 43), for all $\lambda \geq m_1$,

$$P\left( \sup_{0 \leq t \leq T} Z_t \geq \lambda \right) \leq TP\left( \sup_{0 \leq t \leq 1} |Z_t| \geq \lambda \right) \leq 2T \exp\left( \frac{-(\lambda - m_1)^2}{2R_z(0)} \right).$$

Setting $\lambda = \sqrt{\varepsilon_T^{-1} \log T}$ we obtain that as $T \to \infty$,

$$P\left( \sup_{0 \leq t \leq T} Z_t \geq \sqrt{\varepsilon_T^{-1} \log T} \right) \to 0,$$

which yields (2.4).

To see (2.5), let the Gaussian law of $Y$ on $C(\mathbb{R}; \mathbb{R})$ be denoted by $P_y$. Let $R_y$ denote the covariance operator associated with $P_y$, that is,

$$R_y g(t) = \int_{-\infty}^{\infty} R_y(t - s)g(s)ds.$$
with $K_y = R_y^{-1}$ denoting its inverse (defined on the range of $R_y$). We also let $\langle \cdot, \cdot \rangle$ denote the inner product of $L^2(\mathbb{R})$. Fixing $T < \infty$ note that the deterministic function $f_T(t) := \varepsilon_T \exp\left(\frac{1}{4} - \left(\frac{t}{T}\right)^2\right)$ is in the Reproducing Kernel Hilbert Space (RKHS) associated with the process $Y$. Indeed, the Fourier transform of $f_T$ is $\hat{f}(\omega) = c_1 T \varepsilon_T e^{-\omega^2 T^2}$ (for some $c_1 < \infty$), so it follows by Parseval’s theorem that for some $c_2 < \infty$ and all $T$,

$$\langle f_T, K_y f_T \rangle = \int_{-\infty}^{\infty} \frac{|\hat{f}(\omega)|^2}{S_y(\omega)} d\omega = 2\pi \int_{-\infty}^{\infty} |\hat{f}(\omega)|^2 \text{sech}(\omega \pi) d\omega \leq c_2 T \varepsilon_T^2. $$

In particular, $\langle f_T, K_y f_T \rangle$ is finite and the Radon-Nikodým derivative

$$\Lambda_T(Y) = \exp\left(\langle f_T, K_y f_T \rangle - \frac{1}{2} \langle f_T, K_y f_T \rangle \right)$$

is well defined and finite for $P_y$-almost-every $Y$. Since $f_T(t) \geq \varepsilon_T$ for all $-\frac{T}{2} \leq t \leq \frac{T}{2}$, it follows that

$$P\left(\sup_{-\frac{T}{2} \leq t \leq \frac{T}{2}} Y_t \leq \varepsilon_T\right) = P\left(\sup_{-\frac{T}{2} \leq t \leq \frac{T}{2}} \{Y_t - \varepsilon_T\} \leq 0\right)$$

$$\leq P\left(\sup_{-\frac{T}{2} \leq t \leq \frac{T}{2}} \{Y_t - f_T(t)\} \leq 0\right)$$

$$= E\left(\Lambda_T(Y) 1_{\{\sup_{-\frac{T}{2} \leq t \leq \frac{T}{2}} Y_t \leq 0\}}\right)$$

$$\leq E(\Lambda_T(Y)^{q/2}) \left[P\left(\sup_{-\frac{T}{2} \leq t \leq \frac{T}{2}} Y_t \leq 0\right)\right]^{\frac{1}{q}},$$

where $\frac{1}{p} + \frac{1}{q} = 1$. Note that

$$\left(E(\Lambda_T(Y)^{q/2})\right)^{\frac{1}{q}} = \exp\left(\frac{q-1}{2} \langle f_T, K_y f_T \rangle \right).$$

Hence, choosing $q_T = (1/\varepsilon_T) \to \infty$ it follows from (2.7) that

$$\frac{1}{T} \log \left(E(\Lambda_T(Y)^{q/2})\right)^{\frac{1}{q}} \to 0, \quad T \to \infty.$$ 

Substituting in (2.8) and using the stationarity of $Y$ and existence of the limit in (1.3), one has that

$$\limsup_{T \to \infty} \frac{1}{T} \log P\left(\sup_{0 \leq t \leq T} Y_t \leq \varepsilon_T\right) \leq \limsup_{T \to \infty} \frac{1}{T} \log P\left(\sup_{0 \leq t \leq T} Y_t \leq 0\right).$$

The equality in (2.9) is then obvious. The other equality in (2.5) follows by a similar proof, starting with

$$P\left(\sup_{-\frac{T}{2} \leq t \leq \frac{T}{2}} Y_t \leq 0\right) \leq P\left(\sup_{-\frac{T}{2} \leq t \leq \frac{T}{2}} \{Y_t - f_T(t)\} \leq -\varepsilon_T\right)$$

$$\leq E(\Lambda_T(Y)^{q/2}) \left[P\left(\sup_{-\frac{T}{2} \leq t \leq \frac{T}{2}} Y_t \leq -\varepsilon_T\right)\right]^{\frac{1}{q}}.$$

Turning to prove (2.6), set $\varepsilon_T = 3 \max(\gamma_T, (\alpha_T \log T)^{1/3}) \to 0$, and note that

$$\sqrt{T - \alpha_T \varepsilon_T} - \sqrt{\alpha_T \varepsilon_T^{-1} \log T} \geq \gamma_T,$$
once $T$ is large enough that $\alpha T \leq 1/3$. Then, by the independence of $Y_i$ and $Z_i$,
\[
P\left(\inf_{0 \leq t \leq T} Y_t^{(\alpha T)} \geq \gamma T\right) \geq P\left(\inf_{0 \leq t \leq T} Y_t \geq \varepsilon T\right) P\left(\inf_{0 \leq t \leq T} Z_t \geq -\sqrt{\varepsilon T^{-1} \log T}\right).
\]
With the laws of the processes $Y_t$ and $Z_t$ invariant to a change of sign, the inequality \([2.6]\) is thus a direct consequence of \([2.4]\) and \([2.5]\).

The control of $f_n^b(x)$ for $x \in [1 - n^{-1}, 1]$ is achieved in the next lemma by means of the sample path smoothness of $f_n^b(\cdot)$.

**Lemma 2.4.** For any finite $\gamma$, the set of limit points of $C_n = P(f_n^b(x) > \gamma, \forall x \in [1 - n^{-1}, 1])$ is bounded below by some $C_\infty = C_\infty(\gamma) > 0$.

**Proof.** Without loss of generality we assume that $\gamma \geq 0$. Since $x \mapsto E(f_n^b(x)^2)$ is increasing on $[0, \infty)$, with $E(f_n^b(1)^2) = n$, it follows that for any $\lambda > 0$
\[
C_n \geq P\left(f_n^b(x) > \gamma \sqrt{n}, \forall x \in [1 - n^{-1}, 1]\right)
\]
(2.10) \[
\geq P\left(f_n^b(1) > (\lambda + \gamma) \sqrt{n}\right) - P\left(\sup_{(1 - n^{-1}) \leq \xi \leq 1} f_n^{b, \prime}(\xi) \geq \lambda n^{3/2}\right).
\]
We wish to apply Borell’s inequality to bound the second term in \((2.10)\). To this end, note that
\[
f_n^{b, \prime}(\xi) = \sum_{i=0}^{n-1} i b_i \xi^{i-1} = \sum_{i=0}^{n-1} \left(\sum_{j=0}^{i} b_j\right) [i \xi^{i-1} - (i + 1) \xi^{i}] + n \xi^{n-1} \sum_{j=0}^{n-1} b_j.
\]
By Kolmogorov’s maximal inequality,
\[
E\left[\sup_{i \leq n} \left|\sum_{j=0}^{i} b_j\right|\right] \leq c_1 n^{1/2}.
\]
Hence, for some $c_2 > 0$,
\[
E\left[\sup_{1 - n^{-1} \leq \xi \leq 1} f_n^{b, \prime}(\xi)\right] \leq c_2 n^{3/2}.
\]
(2.11) Furthermore, we have that
\[
\sup_{1 - n^{-1} \leq \xi \leq 1} E\left[\frac{1}{n^{1/2}} f_n^{b, \prime}(\xi)\right]^2 = \frac{1}{n^3} \sum_{i=1}^{n-1} i^2 n^{-1/2} \xrightarrow{n \to \infty} \frac{1}{3},
\]
implying, by Borell’s inequality and \((2.11)\), that for some finite $c_3$, all $n$ and any $\lambda \geq c_2$,
\[
(2.12) \quad P\left(\sup_{1 - n^{-1} \leq \xi \leq 1} f_n^{b, \prime}(\xi) \geq \lambda n^{3/2}\right) \leq c_3 e^{-3(\lambda - c_2)^2}/2.
\]
Since $n^{-1/2} f_n^b(1)$ is a standard Normal random variable, it follows that for some positive $c_4 = c_4(\gamma)$, $\lambda = \lambda(\gamma)$ large enough and all $n$,
\[
(2.13) \quad P\left(f_n^b(1) > (\lambda + \gamma) \sqrt{n}\right) \geq c_4 e^{-\lambda^2} \geq 2 c_3 e^{-3(\lambda - c_2)^2}/2.
\]
Substituting \((2.12)\) and \((2.13)\) in \((2.10)\), one concludes that $\lim_{n \to \infty} C_n \geq C_\infty > 0$ as claimed.

The next lemma provides the bounds on the value of $b$ stated in the introduction.
Lemma 2.5. The limit in (1.3) exists, and the constant $b$ there satisfies the bounds $0.4 \leq b \leq 2$.

Proof. The existence of the limit in (1.3) was proved in the course of proving Lemma 2.3. Recall that $R_y(t) \geq e^{-|t|/2}$, the covariance of the stationary Ornstein-Uhlenbeck process $X$. As can be checked by computing the covariance, a representation of the process $\{X_t\}$ can be obtained as

$$X_t = e^{-t/2}V = e^{-t/2}(V - V_1) = e^{-t/2}(W_{t-1} + X_0),$$

for some standard Brownian motions $V$, $W$ and a standard Normal random variable $X_0$ that is independent of $W$. Hence, for $\eta = (e^T - 1)^{-1/2}$,

$$P(\sup_{0 \leq t \leq T} X_t \leq 0) = E[1_{X_0 \leq 0} P(\sup_{0 \leq t \leq e^{T-1}} \{W_t\} \leq -X_0|X_0)]$$

$$= E[1_{X_0 \leq 0} (1 - 2P(W_{e^{T-1}} \geq -X_0|X_0))]$$

$$= \frac{1}{\pi} \int_{-\infty}^{0} \int_{0}^{\eta x} e^{-(x^2+y^2)/2} dy dx$$

$$= \frac{1}{\pi} \arctan(\eta) = \frac{1}{\pi} e^{-T/2}(1 + o(1)).$$

Consequently, Slepian’s lemma implies the bound $b \leq 2$.

The proof of the complementary bound is based on the following observation. Suppose that $X \in \mathbb{R}^n$ and $Y \in \mathbb{R}^n$ are zero-mean, normally distributed random vectors with covariance matrices $\Sigma_x$ and $\Sigma_y$, respectively. If $\Sigma_x - \Sigma_y$ is a positive semidefinite matrix, then the Radon-Nikodým derivative of the law of $Y$ with respect to that of $X$ is at most $(\det \Sigma_x / \det \Sigma_y)^{1/2}$, hence

$$P(Y \in C) \leq \frac{(\det \Sigma_x)^{1/2}}{(\det \Sigma_y)^{1/2}} P(X \in C),$$

for all $C \subset \mathbb{R}^n$ (cf. [Sh, Lemma 3.1]). Indeed, to prove that $b \geq 0.4$, it suffices to show that

$$P(\max_{1 \leq i \leq n} Y_{5i} \leq 0) \leq \exp(-0.5n)$$

for all $n \geq 2$. Let

$$\rho = 2 \text{sech}(5/2) = \frac{2e^{-2.5}}{1 + e^{-5}}, \quad \lambda_0 = 4 \sum_{i=2}^{\infty} \text{sech}(5i/2) = 4 \sum_{i=2}^{\infty} e^{-2.5i}$$

and let $(X_1, \cdots, X_n)$ be independent normal random variables each having zero mean and variance $\lambda := 1 + 2\rho + \lambda_0$. Denote the covariance matrices of $(X_i, 1 \leq i \leq n)$ and $(Y_{5i}, 1 \leq i \leq n)$ by $\Sigma_x$ and $\Sigma_y$, respectively. It is easy to see that $\Sigma_x - \Sigma_y$ is a dominant principal diagonal matrix and as such it is positive semidefinite. Thus, by (2.15),

$$P(\max_{1 \leq i \leq n} Y_{5i} \leq 0) \leq \frac{(\det \Sigma_x)^{1/2}}{(\det \Sigma_y)^{1/2}} P(\max_{1 \leq i \leq n} X_i \leq 0) = \frac{\lambda^{n/2}2^{-n}}{(\det \Sigma_y)^{1/2}}.$$

To estimate $\det \Sigma_y$, let $\Sigma_n = (r_{ij}, 1 \leq i,j \leq n)$ be a tri-diagonal matrix with $r_{ii} = 1 - \lambda_0$, $r_{i+1,i} = r_{i,i-1} = \rho$ and $r_{ij} = 0$ for other $i,j$. Then, $\Sigma_y - \Sigma_n$ is a positive semidefinite matrix and hence

$$\det \Sigma_y \geq \det \Sigma_n := D_n.$$
Since \( D_n = (1 - \lambda_0)D_{n-1} - \rho^2 D_{n-2} \), direct calculation shows that
\[
D_n \geq \left( \frac{1}{2}(1 - \lambda_0 + \sqrt{(1 - \lambda_0)^2 - 4\rho^2}) \right)^n.
\]
Putting the above inequalities together yields
\[
P\left( \max_{1 \leq t \leq n} Y_{2t} \leq 0 \right) \leq \left( \frac{\lambda}{2(1 - \lambda_0 + \sqrt{(1 - \lambda_0)^2 - 4\rho^2})} \right)^{n/2}
= \exp \left\{ 0.5n \ln \left( \frac{\lambda}{2(1 - \lambda_0 + \sqrt{(1 - \lambda_0)^2 - 4\rho^2})} \right) \right\}
\leq \exp(-0.5n)
\]
(here, \( \lambda = 1.3555 \cdots, \rho = 0.163071 \cdots \) and \( \lambda_0 = 0.029361 \cdots \)).

**Remark.** Using a stationary Gaussian process generated from the integrated Brownian motion instead of the Ornstein-Uhlenbeck process in the proof of Lemma 2.5 and applying a new normal comparison inequality, Li and Shao [LiS] recently proved that \( 0.5 < b < 1 \).

### 3. LOWER BOUND FOR THEOREM 1.4

Hereafter let \( \theta_1(x) = x, \theta_2(x) = x^{-1}, \theta_3(x) = -x^{-1} \) and \( \theta_4(x) = -x \) be the symmetry transformations preserved by the Gaussian processes \( \hat{f}_n(x) \) and let \( \gamma_n(x) = \max_{1 \leq j \leq 4} \gamma_n(\theta_j(x)) \) (with the exception of \( x = 0 \) for which \( \gamma_n(0) = \gamma_n(0) \)).

We begin by noting that, with \( I_1 = [0, 1], I_2 = [1, \infty), I_3 = (-\infty, -1] \) and \( I_4 = [-1, 0] \),
\[
P(\hat{f}_n(x) > \gamma_n(x), \forall x \in \mathbb{R}) = P(\hat{f}_n(x) > \gamma_n(x), \forall x \in I_1 \cup I_2 \cup I_3 \cup I_4)
\geq \prod_{i=1}^4 P(\hat{f}_n(x) > \gamma_n(x), \forall x \in I_i)
\geq \left[ P(\hat{f}_n(x) > \gamma_n(x), \forall x \in [0, 1]) \right]^4,
\]
where the first inequality follows by Slepian’s lemma due to the positivity of the covariance \( c_n(x, y) \) of \( \hat{f}_n(x) \), while the second holds because \( c_n(x, y) = c_n(-x, -y) = c_n(\frac{1}{2}, \frac{1}{2}) \). Set \( T = \log n \). The assumptions of Theorem 1.4 imply the existence of the integers \( \log T \ll \tau_T \ll T \) such that \( \delta_n := \sup \{\gamma_n(x) : x \in [1 - \xi_n, 1] \} \rightarrow 0 \) for \( \xi_n = \exp(-\tau_T) \). Recall also our assumption that \( \sup \{\gamma_n(x) : x \in \mathbb{R}, n \} \leq M < \infty \). Applying Slepian’s lemma once more yields that
\[
P(\hat{f}_n(x) > \gamma_n(x), \forall x \in [0, 1])
\geq P\left( \inf_{0 \leq x \leq 1 - \xi_n} \hat{f}_n(x) > M \right) P\left( \inf_{1 - \xi_n \leq x \leq 1 - n^{-1}} \hat{f}_n(x) > \delta_n \right)
\times P\left( \inf_{1 - n^{-1} \leq x \leq 1} \hat{f}_n(x) > M \right)
\geq A_n B_n C_n.
\]
Starting with \( A_n \), note that for \( 1 > x \geq y \geq 0 \) one has
\[
1 \leq g(x, y) = \frac{1 - xy}{\sqrt{(1 - x^2)(1 - y^2)}} \leq \sqrt{\frac{1 - y}{1 - x}}.
\]
and hence, by (2.2), taking \( x = 1 - e^{-t} \) and \( y = 1 - e^{-s} \) we see that for \( x, y \in [0, 1) \),

\[
(3.3) \quad c_n(x, y) \geq \frac{1 - x \vee y}{1 - x \wedge y} = e^{-|t-s|/2}.
\]

Recall that \( \exp(-|t-s|/2) \) is the covariance of the stationary Ornstein-Uhlenbeck process (see (2.14)). In view of (3.3), we have by Slepian’s lemma that

\[
A_n = P\left( \inf_{0 \leq x \leq 1-\xi_n} f_n(x) > M \right) \geq P\left( \inf_{0 \leq t \leq \tau_T} X_t > M \right).
\]

Since \( X_t \) is a centered stationary Gaussian process of positive covariance, yet another application of Slepian’s lemma yields that

\[
(3.4) \quad \liminf_{n \to \infty} \frac{\log A_n}{\log n} \geq \liminf_{T \to \infty} \frac{\tau_T}{T} \log P\left( \inf_{0 \leq t \leq 1} X_t > M \right) = 0
\]

(since the random variable \( \inf_{0 \leq t \leq 1} X_t \) is unbounded).

We next turn to the dominant term \( B_n \). Setting \( z = 1 - x, w = 1 - y \), for all \( x, y \in [1-\xi_n, 1) \), \( n \) large, it follows from (2.2), (2.3) and Lemma 2.1 that

\[
c_n(x, y) \geq \frac{1}{g(x, y)} \geq \frac{2\sqrt{z w}}{z + w} \left[ 1 - \frac{(z - w)^2}{\max(z, w)} \right].
\]

Making yet another change of variables \( z = e^{-t}, w = e^{-s} \), we thus get that for \( \alpha = e^{-\tau_T} \), in the notations of Lemma 2.2,

\[
c_n(x, y) \geq \frac{2e^{-|s-t|}}{1 + e^{-|s-t|}} \left[ 1 - \alpha(1 - e^{-|s-t|})^2 \right] = R^{(\alpha)}(s-t).
\]

With \( R^{(\alpha)}(0) = c_n(x, x) = 1 \), it follows by Slepian’s lemma that

\[
B_n \geq P\left( \inf_{0 \leq t \leq T} Y^{(\alpha)}_t > \delta_n \right).
\]

Since \( \delta_n \to 0 \) and \( \alpha_T \log T \to 0 \) by our choice of \( \tau_T \), it follows by (2.6) of Lemma 2.3 that

\[
(3.5) \quad \liminf_{n \to \infty} \frac{\log B_n}{\log n} \geq -\frac{b}{4}.
\]

Finally, we recall that the sequence \( C_n \) is bounded away from zero by Lemma 2.4. Combining (3.1), (3.2), (3.4) and (3.5), we thus arrive at the stated lower bound

\[
\liminf_{n \to \infty} \frac{\log P^{b}_{n,\gamma_n}}{\log n} \geq -b
\]

of (1.9).

\[\square\]

4. Upper bound for Theorem 1.4

Fixing \( \frac{1}{2} > \delta > 0 \), define the four disjoint intervals \( I_1 = [1 - n^{-\delta}, 1 - n^{-(1-\delta)}] \) and \( I_j = \theta_j(I_1), j = 2, 3, 4 \). Let \( V = \bigcup_{j=1}^4 I_j \) and \( U = \bigcup_{j=1}^4 \{ (x, y) : x, y \in I_j \} \).

The crucial tool in the proof of the upper bound is the following lemma, whose proof is deferred to the end of this section:

Lemma 4.1. For all \( n \) sufficiently large there exist 0 \( \leq \alpha_n \leq n^{-\delta/2} \) such that

\[
(4.1) \quad c_n(x, y) \leq \frac{1 - \alpha_n}{g(x, y)} 1_{(x, y) \in U} + \alpha_n \quad \forall x, y \in V.
\]
Equipped with Lemma 4.1 we show how to complete the proof of the upper bound. Let \( \{N, b^{(j)}, j = 1, 2, 3, 4, i = 0, \ldots \} \) be independent, identically distributed standard normal random variables. For \( x \in \mathcal{I}_1 \) consider the infinite random polynomials \( \tilde{f}_\infty^{(j)}(x) = \sqrt{1 - x^2} \sum_{i=0}^{\infty} b_i^{(j)} x^i \) which are for \( j = 1, 2, 3, 4 \) well defined i.i.d. centered Gaussian processes of covariance function \( 1/g(x, y) \). Recall that \( g(x, y) \) is invariant to an application of each of the invertible transformations \( \theta_j(\cdot), j = 2, 3, 4 \), on both \( x \) and \( y \). Each such transformation is a one to one map of \( \mathcal{I}_j \) to \( \mathcal{I}_1 \). Hence, the right hand side of (4.1) represents the covariance of the centered Gaussian field \( \tilde{f}_n(\cdot) \) defined on \( \mathcal{V} \), of the form

\[
\tilde{f}_n(x) = \sqrt{1 - \alpha_n} \sum_{j=1}^{4} 1_{x \in \mathcal{I}_j} \tilde{f}_\infty^{(j)}(\theta_j(x)) + \sqrt{\alpha_n} N.
\]

Observe that the assumptions of Theorem 1.4 imply that \( \eta_n := n^{-\delta/8} \sup \{-\gamma_n(x) : x \in \mathcal{V}\} \to 0 \) as \( n \to \infty \). With \( g(x, x) = 1 \) for all \( x \in \mathcal{V} \), relying upon (4.1) and the positivity of \( 1/g(x, y) \) we get by two applications of Slepian’s lemma that for all \( n \) sufficiently large

\[
P_{n, \eta_n} = P\left( \sup_{x \in \mathcal{V}} \tilde{f}_n(x) \leq \eta_n \right) \leq P\left( \sup_{x \in \mathcal{V}} \tilde{f}_n(x) \leq \eta_n \right) \leq P\left( N \leq -n^{\delta/8} + \sum_{j=1}^{4} P\left( \sup_{x \in \mathcal{I}_j} \tilde{f}_\infty(\theta_j(x)) \leq \frac{2\eta_n}{\sqrt{1 - \alpha_n}} \right) \right)
\]

\[
\leq e^{-n^{\delta/4}/2} + P\left( \sup_{x \in \mathcal{I}_1} \tilde{f}_\infty(x) \leq 3\eta_n \right)^4.
\]

Hence, it is enough to show that

\[
\limsup_{\delta \to 0} \limsup_{n \to \infty} \frac{1}{\log n} \log P\left( \sup_{x \in \mathcal{I}_1} \tilde{f}_\infty(x) \leq 3\eta_n \right) \leq \frac{b}{4}.
\]

The change of variables \( x = 1 - z = 1 - e^{-t}, y = 1 - w = 1 - e^{-s} \) yields, by (2.3) and Lemma 2.1 that for all sufficiently large \( n \) and all \( x, y \in \mathcal{I}_1 \),

\[
\frac{1}{g(x, y)} \leq \frac{2\sqrt{2w}}{z + w} = \text{sech}\left( \frac{t - s}{2} \right).
\]

For \( T = \log n, T' = (1 - 2\delta)T \) and \( \epsilon_{T'} := 3\eta_n \to 0 \), by yet another application of Slepian’s lemma and the stationarity of the process \( Y_t \) of Lemma 2.2 it follows from (4.4) that

\[
P\left( \sup_{x \in \mathcal{I}_1} \tilde{f}_\infty(x) \leq 3\eta_n \right) \leq P\left( \sup_{t \in [T', (1 - \delta)T]} Y_t \leq 3\eta_n \right) \leq P\left( \sup_{0 \leq t \leq T'} Y_t \leq \epsilon_{T'} \right).
\]

Consequently, by (2.5),

\[
\limsup_{n \to \infty} \frac{1}{\log n} \log P\left( \sup_{x \in \mathcal{I}_1} \tilde{f}_\infty(x) \leq 3\eta_n \right) \leq (1 - 2\delta) \limsup_{T \to \infty} \frac{1}{T} \log P\left( \sup_{0 \leq t \leq T} Y_t \leq \epsilon_T \right) = -(1 - 2\delta) \frac{b}{4}.
\]

Taking \( \delta \to 0 \), we see that (4.4) implies (4.3), hence the proof of the upper bound in (1.3), modulo the proof of Lemma 4.1 which we provide next.
Moreover, in (4.9), we conclude that on the diagonal (4.7b)
\[ g(x^n, y^n) \leq \alpha_n g(x, y), \quad x, y \in \mathcal{I}_1, \]
by the symmetry relations \( g(x, y) = g(-x, -y) = g(\frac{1}{z}, \frac{1}{y}) \) to show that
\[ g(x^n, y^n) \leq (1 - \alpha_n) + \alpha_n g(x, y), \quad x, y \in \mathcal{I}_1, \]
Fixing \( x \in \mathcal{I}_1 \), the change of variables \( y = x(1 - \sqrt{1 - \frac{w}{z}}) \) where \( z = 1 - x \) and \( w = 1 - y \). It follows from (4.4) that for all \( n \) sufficiently large,
\[ g(x, y) - 1 \geq \frac{z + w}{2\sqrt{zw}} - 1 = \frac{1}{2} \left( 1 - \frac{\sqrt{w}}{z} \right)^2 = \frac{\eta^2}{2}. \]
Moreover, when \( n \) is large enough,
\[ \sqrt{1 - x^{2n}} \geq \frac{2}{3} \quad \forall x, y \in \mathcal{I}_1, \]
so that,
\[ \frac{g(x^n, y^n) - 1}{g(x, y) - 1} \leq \frac{2}{\eta^2} \frac{1 - x^n y^n - \sqrt{1 - x^{2n}} \sqrt{1 - y^{2n}}}{\sqrt{1 - x^{2n}} \sqrt{1 - y^{2n}}} \leq \frac{3}{\eta^2} h(\eta), \]
where
\[ h(\eta) := 1 - x^n y(\eta)^n - \sqrt{1 - x^{2n}} \sqrt{1 - y(\eta)^{2n}}. \]
Note that \( y(0) = x \), hence \( h(0) = 0 \). It is not hard to check that \( h'(0) = 0 \) and
\[ h''(\xi) = ny''(\xi) \left( \frac{1}{\sqrt{1 - y^{2n}}} y^{2n-1} - x^n y^{n-1} \right) \]
\[ + ny'(\xi)^2 \left[ (2n-1)y^{2n-2} \frac{1 - x^{2n}}{\sqrt{1 - y^{2n}}} + ny^{2n-2} \frac{1 - y^{2n}}{\sqrt{1 - y^{2n}}}((n-1)x^n y^{n-2}) \right], \]
evaluated at \( y = y(\xi) \). Observing that \( |y'(\xi)| \leq 2, y''(\xi) \in [-2, 0] \) and \( x^n \leq y(\xi)^n \leq y(\eta)^n \leq e^{-c_1 n} \) for all \( \xi \in [0, \eta] \), it is easy to check that there exists a universal finite constant \( c_1 \) such that
\[ \sup_{\xi \in [0, \eta]} h''(\xi) \leq c_1 y(\eta)^n \leq c_1 e^{-c_1 n}, \]
for all \( n \) large enough and any \( x, y \in \mathcal{I}_1 \). Hence, \( h(\eta) \leq \frac{1}{2} c_1 e^{-c_1 n} \eta^2 \). Substituting in (4.9), we conclude that
\[ \sup_{x, y \in \mathcal{I}_1} \frac{g(x^n, y^n) - 1}{g(x, y) - 1} \leq 2c_1 e^{-c_1 n}, \]
proving (4.7a).

Turning to the proof of (4.7b), we assume first that \( x \in \mathcal{I}_2 \) and \( y \in \mathcal{I}_2 \cup \mathcal{I}_3 \).
Then, \( x, y \in \mathcal{I}_1 \) with \( \sqrt{1 - x^2} \sqrt{1 - y^2} \leq 1 \) and (4.8) holding for \( x \) and \( y \).

Moreover, \( x^n \leq e^{-c_1 n} \), so we have in this case that
\[ \frac{g(x^n, y^n)}{g(x, y)} \leq \frac{3}{2} \frac{|x^n - y^n|}{|x - y|} \leq \frac{3}{2} \sum_{k=0}^{n-1} x^k |y|^{-(n-1-k)} \leq 2ne^{-c_1 n}. \]
In the remaining case of \( x \in I_1 \) and \( y \in I_4 \) we have that \( |y|^n \leq \varepsilon^{-n \delta} \), hence \( g(x^n, y^n) \leq 2 \) while
\[
\frac{1}{g(x, y)} = \frac{\sqrt{1 - x^2} \sqrt{1 - y^2}}{1 + |xy|} \leq [1 - (1 - n^{-\delta})^2] \leq 2n^{-\delta},
\]
thus completing the proof of (4.7b). \( \square \)

5. PROOF OF THEOREM 1.3

Our proof of Theorem 1.3 combines the Komlós-Major-Tusnády strong approximation theorem with Theorem 1.4. To this end, note that for every \( k \) and \( |x| \leq 1 \), the sequence \( \{(1 - x^2)x^{2j} : j = 0, \ldots, k - 1\} \cup \{x^{2k}\} \) is a probability distribution, hence for any real valued \( s_j \),
\[
(5.1) \quad \left| s_0 + \sum_{j=1}^k (s_j - s_{j-1})x^{2j} \right| = \left| s_kx^{2k} + (1 - x^2) \sum_{j=0}^{k-1} s_jx^{2j} \right| \leq \max_{0 \leq j \leq k} |s_j|.
\]
Recall that \( E(a_i) = 0 \) and \( E(a_i^2) = 1 \). Hence, applying the strong approximation theorem of [KMT] twice we can redefine \( \{a_i, 0 \leq i \leq n - 1\} \) on a new probability space with a sequence of independent standard Normal random variables \( \{x_i, 0 \leq i \leq n - 1\} \) such that for any \( p \geq 2 \), some \( c_p < \infty \), all \( t > 0 \) and \( n \),
\[
(5.2) \quad P \left( \max_{0 \leq j \leq (n-1)/2} \left| \sum_{i=0}^{j} a_{2i} - \sum_{i=0}^{j} b_{2i} \right| \geq t \right) + P \left( \max_{0 \leq j \leq (n-2)/2} \left| \sum_{i=0}^{j} a_{2i+1} - \sum_{i=0}^{j} b_{2i+1} \right| \geq t \right) \leq c_p n E|a_0|^p t^{-p}.
\]
Let
\[
g_k(x) := x^{k-1}f_k(x^{-1}) = \sum_{i=0}^{k-1} a_i x^{k-1-i},
\]
and for \( k \in \{1, \ldots, n\} \), define
\[
f_k^b(x) = \sum_{i=0}^{k-1} b_i x^i, \quad g_k^b(x) = x^{k-1}f_k^b(x^{-1}).
\]
Let \( \sigma_k(x) := \sqrt{E(f_k(x)^2)} = \sqrt{|1 - x^{2k}|/|1 - x^2|} \), when \( |x| \neq 1 \) with \( \sigma_k(\pm 1) = \sqrt{E(f_k(\pm 1)^2)} = \sqrt{k} \). Define \( f_k(x) := f_k(x)/\sigma_k(x) \) and \( f_k^b(x) := f_k^b(x)/\sigma_k(x) \). As \( \sigma_k(x) = \sqrt{E(g_k(x)^2)} \), we shall also use \( \gamma_k(x) = g_k(x)/\sigma_k(x) \) and \( \gamma_k^b(x) = g_k^b(x)/\sigma_k(x) \). Since
\[
(5.3) \quad \sum_{i=0}^{k} a_i x^i - \sum_{i=0}^{k} b_i x^i \leq \sum_{j=0}^{[k/2]} (a_{2j} - b_{2j})x^{2j} + \sum_{j=0}^{[(k-1)/2]} (a_{2j+1} - b_{2j+1})x^{2j+1},
\]
Indeed, bounding $g_k - g_k^b$ amounts to changing $(a_i, b_i)$ to $(a_{k-1-i}, b_{k-1-i})$, resulting with using $s_j = \sum_{i=0}^j (a_{k-1-2i} - b_{k-1-2i})$ once and $s_j = \sum_{i=0}^j (a_{k-1-3i} - b_{k-1-3i})$ once. One controls all these as before, but for doubling the total approximation error.

In order to apply effectively the strong approximation results, we need that contributions to the value of $f_n(x)$ come from many variables. This obviously is easier for $|x| - 1$ small. In order to avoid the appearance of zeros in other locations, we decompose $f_n$ to the dominant “bulk term”, which will not be too negative everywhere and will be rather far from 0 for $|x| - 1$ small, and to “boundary terms”, which involve a small number of coefficients and thus can be made to have prescribed positive values with a not too small probability.

In order to define precisely the different regions considered for values of $x$ and the splitting into bulk and boundary terms, we introduce, for $n$ large enough odd integers, a few $n$-dependent parameters as follows:

\begin{align*}
    p_n : & \quad p_n \uparrow \infty, \quad c_p E|a_0|^{p_*} \leq n \\
    \epsilon = \epsilon_n : & \quad \epsilon_n \downarrow 0, \\
    & \quad \epsilon_n \geq \max \{20/p_n, (\log n)^{-1/2}\}, \\
    & \quad 2n^{3\epsilon_n} = 2^j + 2s2^s \\
    & \quad \text{for some integer } j \\
    m = m_n : & \quad m_n \to \infty, \quad m_n = 2n^{3\epsilon_n} \\
    \gamma_n(x) : & \quad \gamma_n \to 0, \\
    & \quad \gamma_n(x) = \max \{0, \gamma_n(x), \gamma_n(x^{-1})\} \\
    \rho_n : & \quad \rho_n \to 0, \\
    & \quad \rho_n = \sup_{|x| \leq 1 - m^{-1}} \{\sigma_n(x)\gamma_n(x)\} \\
    r = r_n : & \quad r_n = cn^{-\delta/2} \\
    \xi_n(x) : & \quad \xi_n(x) = 6x^m \sigma_{n-2m}(x)\gamma_n(x)
\end{align*}

In order to state the decomposition alluded to above, first partition the interval $[-1, 1]$ to $\mathcal{I} = \{x : |x| \geq 1 - 0.5n^{-\epsilon}\}$ and $\mathcal{I}^c = [-1, 1] \setminus \mathcal{I}$. We note that $2r + \xi_n(x) \geq \sigma_n(x)\gamma_n(x)$ for all $x \in \mathcal{I}$. Next, let $f_n = f_n^L + f_n^M + f_n^H$ where

\begin{align*}
    f_n^L(x) = \sum_{i=0}^{m-1} a_i x^i, \quad f_n^M(x) = \sum_{i=m}^{n-m-1} a_i x^i, \quad f_n^H(x) = \sum_{i=n-m}^{n-1} a_i x^i.
\end{align*}
Similarly, we let \( g_n = g_n^L + g_n^M + g_n^H \) with \( g_n^L(x) = x^{n-1} f_n^L(x^{-1}) \), etc. With these definitions, we have the inclusions

\[
\{ f_n(x) > \gamma_n(x), \quad \forall \, x \in \mathbb{R} \} \supset \{ f_n(x) > \gamma_n(x), \quad \forall \, x \in [-1, 1] \}
\]

\[
\{ f_n(x) > \gamma_n(x), \quad \forall \, x \in [-1, 1] \} \supset \{ f_n^M(x) > \xi_n(x), \quad \forall \, x \in \mathcal{I} \}
\]

\[
\cap \{ f_n^M(x) > -r, \quad g_n^M(x) > -r, \quad \forall \, x \in \mathcal{I}^c \}
\]

\[
P \left( f_n^L(x) > 3r, \quad g_n^L(x) > -r, \quad \forall \, x \in [-1, 1] \right)
\]

\[
P \left( f_n^H(x) \geq -r, \quad g_n^H(x) > 3r, \quad \forall \, x \in [-1, 1] \right)
\]

(\( f_n^M, g_n^M \) are the “bulk terms” whereas \( f_n^L, g_n^L, f_n^H, g_n^H \) are the “boundary terms”). Since the polynomial pairs \( (f_n^M, g_n^M) \), \( (f_n^L, g_n^L) \) and \( (f_n^H, g_n^H) \) are mutually independent, it follows that

\[
P_{n, \gamma_n} = P \left( f_n(x) > \gamma_n(x), \quad \forall \, x \in \mathbb{R} \right)
\]

\[
\geq P \left( \{ f_n^M(x) > \xi_n(x), \quad g_n^M(x) > \xi_n(x), \quad \forall \, x \in \mathcal{I} \}
\]

\[
\cap \{ f_n^M(x) > -r, \quad g_n^M(x) > -r, \quad \forall \, x \in \mathcal{I}^c \} \right)
\]

\[
P \left( f_n^L(x) > 3r, \quad g_n^L(x) > -r, \quad \forall \, x \in [-1, 1] \right)
\]

\[
P \left( f_n^H(x) \geq -r, \quad g_n^H(x) > 3r, \quad \forall \, x \in [-1, 1] \right)
\]

(5.8)

Note that \( g_n^M \) and \( f_n^M \) are identically distributed, as are the polynomial pairs \( x^{-m}(f_n^M, g_n^M) \) and \( (f_{n-2m}, g_{n-2m}) \). Thus, we have that

\[
P \left( \{ f_n^M(x) > \xi_n(x), \quad g_n^M(x) > \xi_n(x), \quad \forall \, x \in \mathcal{I} \}
\]

\[
\cap \{ f_n^M(x) > -r, \quad g_n^M(x) > -r, \quad \forall \, x \in \mathcal{I}^c \} \right)
\]

\[
\geq P \left( f_{n-2m}(x) > 6\gamma_n(x), \quad g_{n-2m}(x) > 6\gamma_n(x), \quad \forall \, x \in \mathcal{I} \right)
\]

\[
-2P \left( f_n^M(x) \leq -r, \quad \forall \, x \in \mathcal{I} \right)
\]

:= Q_1 - 2Q_2.

Since the polynomial pairs \( (f_n^L, g_n^L), (g_n^H, f_n^H) \) and \( (f_n, x^{n-m}g_m) \) have identical laws, it now follows that

\[
P_{n, \gamma_n} \geq (Q_1 - 2Q_2)(Q_3 - Q_4)^2,
\]

where

\[
Q_3 := P \left( f_m(x) > 3r, \quad \forall \, x \in [-1, 1], \quad x^{n-m}g_m(x) \geq -r, \quad \forall \, |x| \in [1 - m^{-1}, 1] \right)
\]

and

\[
Q_4 := P \left( x^{n-m}g_m(x) \leq -r, \quad \forall \, |x| \leq 1 - m^{-1} \right).
\]

To deal with the dominant term \( Q_1 \), we consider (5.4) and (5.5) for \( p = p_n \) as above, \( k = n - 2m \), and \( t = n^{r/4} \). Noting that

\[
\eta_n = \sup \{ 6\gamma_n(x) + 4t/\sigma_{n-2m}(x) : x \in \mathcal{I} \}
\]
approaches zero as $n \to \infty$, we get that for all $n$ large enough,

\[
Q_1 \geq P \left( \frac{f^b_{n-2m}(x)}{g^b_{n-2m}(x)} > \eta_n, \quad \forall x \in I \right) - 2n^{-3}
\]

\[
\geq P \left( \frac{f^b_{n-2m}(x)}{g^b_{n-2m}(x)} > \eta_n \sigma_{n-2m}(x), \quad \forall ||x|-1| \leq n^{-\epsilon_n} \right) - 2n^{-3}
\]

(5.9)

where the last inequality follows by applying Theorem 1.4 for threshold $\eta_n \to 0$ for $||x|-1| \leq n^{-\epsilon_n}$ and zero otherwise.

Turning to estimate $Q_2$, recall that $f^M_n$ has the same distribution as $x^n f_{n-2m}$ and $m = 2n^{3\epsilon}$. Recall also that $\epsilon \geq (\log n)^{-1/2}$, implying that $n^\epsilon \exp(-n^\epsilon) \to 0$ for any fixed $c < \infty$. Hence, for all $n$ large enough,

\[
Q_2 \leq P \left( \sup_{x \in I^c} |x|^m |f_{n-2m}(x)| \geq r \right)
\]

\[
\leq P \left( \sup_{x \in I^c} |f_{n-2m}(x)| \geq cn^{-3/2} \left( 1 - \frac{1}{2n^\epsilon} \right)^{-2n^{3\epsilon}} \right)
\]

\[
\leq P \left( \sup_{x \in I^c} |f_{n-2m}(x)| \geq 2 \exp(n^\epsilon) \right).
\]

Observe that for any $x, y \in [-1, 1]$,

\[
E \left( |f_{n-2m}(x) - f_{n-2m}(y)|^2 \right) \leq \sum_{i=1}^{n} (x^i - y^i)^2 \leq (x - y)^2 n^3.
\]

Recall the following well known lemma (see [Sto] for a proof).

**Lemma 5.1.** Let $\{T_x, x \in [a, b]\}$ be an a.s. continuous stochastic process with $T_a = 0$. Assume that

\[
\forall \ x, y \in [a, b], \quad E|T_x - T_y|^2 \leq K(x - y)^2.
\]

Then, we have

\[
E \left( \sup_{x \in [a, b]} T_x^2 \right) \leq 4K(b - a)^2.
\]

Applying Lemma 5.1 for $T_x = f_{n-2m}(x) - f_{n-2m}(0)$, first when $x \in [0, 1]$, then when $x \in [-1, 0]$, we get by Markov’s inequality that for all $n$ large enough, and any $c_1 < \infty$ (for our use, $c_1 = 3$ will do),

\[
Q_2 \leq P \left( |a_0| \geq \exp(n^\epsilon) \right) + P \left( \sup_{|x| \leq 1} T_x^2 \geq \exp(2n^\epsilon) \right)
\]

(5.10)

\[
\leq \exp(-2n^\epsilon) \left( 1 + E \left( \sup_{|x| \leq 1} T_x^2 \right) \right) = o(n^{-c_1}).
\]

Recall that $m = 2n^{3\epsilon}$ and $\epsilon_n \to 0$, so with $g_m$ and $f_m$ of identical law, it follows that for all $n$ large enough,

\[
Q_4 \leq P \left( \sup_{|x| \leq 1-m^{-1}} |x|^{n-m} |f_m(x)| \geq r \right) \leq P \left( \sup_{|x| \leq 1-m^{-1}} |f_m(x)| \geq 2 \exp(\sqrt{n}) \right).
\]

Similarly to the derivation of (5.10), by twice applying Lemma 5.1 for $T_x = f_m(x) - f_m(0)$, then using Markov’s inequality, we get that $Q_4 \leq \exp(-n^{1/3})$ for all $n$ large enough. The lower bound $P_{n, 3\epsilon_n} \geq n^{-b+o(1)}$ in Theorem 1.3 is thus a direct consequence of the bounds (5.9), (5.10) and Lemma 7.2 below which provides the estimate $Q_3 \geq n^{-c_2 \epsilon}$ with $\epsilon = \epsilon_n \to 0$ and $c_2 < \infty$ fixed.
Turning to the upper bound $P_n - n^{-b+o(1)}$ in Theorem 1.3, let $\eta := \inf \{ \gamma_n(x): ||x| - 1| \leq n^{-c} \}$. Recall that $\eta_n \to 0$ by our assumptions. Then, similarly to the derivation of (5.20), now with $m = 0$, we see that for all $n$ large enough

$$P_n = P(\hat{f}_n(x) > \gamma_n(x), \quad \forall x \in \mathbb{R})$$

$$\leq P(\hat{f}_n(x) > \eta_n, \quad \hat{g}_n(x) > \eta_n, \quad \forall x \in \mathcal{I})$$

$$\leq P(\hat{f}_n(x) > \eta_n - n^{-c/8}, \quad \hat{g}_n(x) > \eta_n - n^{-c/8}, \quad \forall x \in \mathcal{I}) + 2n^{-3}$$

$$\leq n^{-b+o(1)}$$

(The last inequality follows by Theorem 1.4 for a threshold $\eta_n - n^{-c/8}$ when $x \in \mathcal{I} \cup \{ x : x^{-1} \in \mathcal{I} \}$ and $-\infty$ otherwise).

**Lemma 5.2.** Suppose $a_i$ are i.i.d. with $E(a_0) = 0$ and $E(a_0^2) = 1$. There exists $c < \infty$ and an integer $s$ such that for all $m = 2^{k+1} + 2s2^s$ and $k$ large enough,

$$P(\hat{f}_n(x) > m^{-2}, \quad \forall x \in [-1,1], \quad xg_m(x) > 0, \quad \forall |x| \in [1 - 2^{-k}, 1]) \geq m^{-c}.$$  

**Proof.** Define the intervals $\mathcal{J}_j = \{ x : 1 - 2^{-j} \leq |x| \leq 1 - 2^{-j-1} \}$ for $j = 1, \ldots, k-1$ and $\mathcal{J}_k = \{ x : 1 - 2^{-k} \leq |x| \leq 1 \}$. Throughout this proof, $\tilde{l}_j := 2^j$ for integer $j$, and complements are taken inside the interval $[-1,1]$.

The proof of the lemma is based on decomposing $f_m$ to a sum (over a number of terms logarithmic in $m$) of polynomials $f_j$, such that for each $x \in \mathcal{J}_j$, $f_j(x)$ is large while $f_j(x)$, $i \neq j$, are not too large; at the same time, $g_m(x)$ is decomposed to a sum of polynomials all but the highest order of which are large and positive on $\mathcal{J}_k$, while the latter is not too negative on $\mathcal{J}_k$. Unfortunately, we need to introduce a few constants in order to define explicitly this decomposition.

Note first that for some $c_0 < \infty$ which does not depend on $k$,

$$P_n - n^{-2}, \quad \forall x \in [-1,1], \quad xg_m(x) > 0, \quad \forall |x| \in [1 - 2^{-k}, 1]) \geq m^{-c}.$$  

Define $c_1 = c_0 + 1$. In Lemma 5.3 below, we define a constant $\theta_1 = \theta_1(c_1) > 0$. Define then $\theta = P(|\mathcal{N}| \leq 1)\theta_1/2 > 0$, where $\mathcal{N}$ is a standard Gaussian random variable of zero mean and unit variance. Since $E(a_0) = 0, E(a_0^2) = 1$, we can use Strassen’s weak approximation theorem (see [68] or [CS, p. 89]), to deduce the existence of independent standard Normal random variables $\{ b_i, i \geq 0 \}$ such that, for all $j \geq j_0 \geq 4$,

$$P\left( \max_{0 \leq \ell \leq 2^j} \left| \sum_{i=0}^{\ell} a_{2i} - \sum_{i=0}^{\ell} b_{2i} \right| + \max_{0 \leq \ell \leq 2^j} \left| \sum_{i=0}^{\ell} a_{2i+1} - \sum_{i=0}^{\ell} b_{2i+1} \right| \geq 2^{j/2-3} \right) \leq \theta.$$  

Finally, since $Ea = 0$ and $Ea^2 = 1$ there exists $\alpha > 0$ such that $P(|a - \alpha| \leq \delta) > 0$ for all $\delta > 0$. Fixing such $\alpha$, define $s > j_0$ such that

$$\frac{\alpha}{10} - \sum_{i=s}^{\infty} 2^{i/2} x_i^2 \geq 0, \quad \forall x \in \mathcal{J}_0 := \{ x : |x| \leq 1 - 2^{-s} \}, \quad l_i := \tilde{l}_i + 2s2^s.$$  

Such an $s$ always exists because the sum in (5.14) tends to 0 in $s$. Note that $s$ does not depend on $k$ and all estimates above are valid uniformly for all $k$ large.
enough. We write \( l = l_s \) and note that \( \{ \mathcal{J}_0, \mathcal{J}_s, \mathcal{J}_{s+1}, \ldots, \mathcal{J}_k \} \) form a partition of the interval \([-1,1]\). We keep \( s \) fixed throughout the rest of the proof.

As mentioned above, the proof of the lemma is based on decomposing \( f_m \) to a sum (over \( k - s + 2 \) terms, i.e. a number of terms logarithmic in \( m \)) of polynomials \( f^j, j = 0, s, s + 1, \ldots, k \), while decomposing \( g_m(x) \) to a similar sum of \( k - s + 2 \) polynomials. Specifically, we write

\[
f_m(x) = f^0(x) + \sum_{j=s}^{k} x^j f^j(x),
\]

where \( f^0 = f_{ls} \) and

\[
f^j(x) = \sum_{i=0}^{2^j-1} a_{i+l_j} x^i.
\]

Similarly,

\[
g_m(x) = x^{m-l_s} g^0(x) + \sum_{j=s}^{k} x^{m-l_j+i} g^j(x),
\]

where \( g^0 = g_{ls} \) and

\[
g^j(x) = \sum_{i=0}^{2^j-1} a_{i+l_j} x^{2^j-1-i}.
\]

One checks that for \( k \) large enough, it holds that

\[
m^{-2} \leq \min \left\{ \frac{\alpha}{10}, \inf_{x \in \mathcal{J}_j,j=s,\ldots,k} 2^{j/2} x^j \right\}.
\]

Moreover, by (5.12), for all \( k \geq s \),

\[
(c_0 - 1) 2^{j/2} x^j - \sum_{i=s,i \neq j}^{k} 2^{j/2} x^i \geq 0, \quad \forall x \in \mathcal{J}_j, \quad j = s, \ldots, k.
\]

It follows that

\[
\{ f_m(x) > m^{-2}, \quad \forall x \in [-1,1] \}
\]

\[
\sup \left\{ \bigcap_{j=s}^{k} \{ f^j(x) > c_0 2^{j/2}, \quad \forall x \in \mathcal{J}_j, \quad f^j(x) \geq -2^{j/2}, \quad \forall x \in \mathcal{J}^c_j \} \right\}
\]

\[
\cap \{ f^0(x) > \frac{\alpha}{5}, \quad \forall x \in \mathcal{J}_0, \quad f^0(x) \geq 0, \quad \forall x \in \mathcal{J}^c_0 \}.
\]

Note that for all \( x \in [-1,1] \),

\[
\{ x g_m(x) \geq 0 \} \supset \{ x g^0(x) \geq -2^{k/2} \} \bigcap_{j=s}^{k} \{ x g^j(x) \geq c_0 2^{j/2} \}.
\]

The polynomial pairs \((f^j, g^j), j = 0, s, \ldots, k\), are mutually independent, with \((f^0, g^0)\) having the same law as \((f_1, g_1)\), while \((f^j, g^j)\) has the same law as \((f_{2^j}, g_{2^j})\)
We first show that \( \eta \) does not depend on \( c \). Toward this end, let \( Q(z) := \alpha(1 + z + \cdots + z^{d-1}) \), noting that \( Q(z) \) is monotone increasing on \([-1,1]\), with \( Q(-1/2) \geq \alpha/4 \), implying that \( Q(z) \geq \alpha/4 \) for all \( z \in [0,1] \). Thus, for each \( s \) we have \( \delta_s \in (0,\alpha) \) such that \( f_i(x) > \alpha/5 \) whenever \( x \in [0,1] \) and \( |a_i - \alpha| \leq \delta_s \). Further taking \( a_{2i} \geq a_{2i+1} \geq 0 \) for \( i = 0, \ldots, l_s - 1 \) guarantees that \( f_i(x) \geq 0 \) for all \( x \in [-1,1] \).

Considering only such \( \{a_i\} \), we also have that \( xg_1(x) \) is bounded away from zero, and hence, combining the above and using \( 2^{k/2} \geq 2\epsilon / \alpha \), we have that

\[
\liminf_{k \to \infty} \eta_s \geq 0.
\]

To estimate \( q_j \), we note that \( xg_1(x) = x^2g_2(x) = x^2g_{2J-1} + x^2g_{2L-1} \). Thus, combining (5.1), (5.3) and (5.13), it follows that for all \( j \in \{s, \ldots, k\} \),

\[
q_j \geq P(|b_{J-1}| \leq 1)q_j^* - \theta,
\]

where

\[
q_j^* := P\left(f_{2j-1}^*(x) \geq c_12^{j/2}, \forall x \in J_j, f_{2j-1}^*(x) \geq -2^{(j-1)/2}, \forall x \in J_j^c,
\]

\[
g_{2j-1}^*(x) \geq c_12^{j/2}, \forall x \in J_k^c
\]

for, say, \( c_1 = c_0 + 1 \). Slepian’s lemma thus yields that for all \( k \geq j \geq s \),

\[
q_j^* \geq P\left(f_{2j-1}^*(x) \geq c_12^{j/2}, \forall x \in [1-2^{-j},1]\right)^4 \quad P\left(f_{2j-1}^*(x) \geq -2^{(j-1)/2}, \forall x \in [0,1-2^{-j}]\right)^2 := \tilde{q}_j^*.
\]

Note that \( \tilde{q}_j^* \) does not depend on \( k \), and in fact it depends on \( c_1 \) and \( j \) only. The following lemma provides estimates on \( \tilde{q}_j^* \) while defining the constant \( \theta_1 \).
Lemma 5.3. There exists a constant \( \theta_1 > 0 \) such that for all \( j \geq 4 \),
\[
\hat{q}_j \geq \theta_1.
\]

Applying (5.22) using \( \theta = \frac{1}{2} P(|b| \leq 1) \theta_1 \) then leads to \( q_j \geq \theta \) for all \( j \geq s \). In view of (5.21) and (5.19) this proves (5.11). \( \square \)

Proof of Lemma 5.3

Note that \( \sigma_{2i-1}(x) \geq 2^{i/2-1} \) when \( x \in [1 - 2^{-j}, 1] \), hence by Lemma 2.4 for some \( \xi_1 > 0 \) and all \( j \) large enough,
\[
P\left( f_{2j}^b(x) \geq c_1 2^{j/2}, \forall x \in [1 - 2^{-j}, 1] \right)
\geq P\left( f_{2j}^b(x) \geq 2c_1, \forall x \in [1 - 1/(2^j - 1), 1] \right) \geq \xi_1.
\]

Note that \( \sigma_{2i-1}(x) \leq 1/\sqrt{1-x} \leq 2^{i/2} \) for \( x \in [0, 1-2^{-i}] \). Hence, by Slepian’s lemma and (3.3), we have that for the Ornstein-Uhlenbeck process \( X_t \) of (2.14),
\[
P\left( f_{2j}^b(x) \geq -2(2^{j-1}/2, \forall x \in [0,1-2^-j])
\geq \prod_{i=0}^{j-1} P\left( f_{2i}^b(x) \geq -2(2^{-i-1/2}, \forall x \in [1-2^{-i-1}, 1-2^{-i-1}])
\geq \prod_{i=0}^{j-1} P\left( X_t \geq -2^{j-i/2-1}, \forall t \in [i \ln 2, (i + 1) \ln 2])
= \prod_{i=1}^{j} P\left( \inf_{0 \leq t \leq 2^i} X_t \geq -2^{i/2-1} \right)
\geq \prod_{i=1}^{\infty} \left[ 1 - P\left( \sup_{0 \leq t \leq 2^i} X_t \geq 2^{i/2-1} \right) \right] =: \xi_2
\]
and \( \xi_2 > 0 \) since \( E(\sup_{t \in [0, \ln 2]} X_t) < \infty \). This completes the proof. \( \square \)

6. Proof of Theorem 1.1

Part a) of Theorem 1.1 is a direct consequence of Theorem 1.3 with \( \gamma_n = 0 \). Thus, it only remains to prove part b). Fixing \( \mu \neq 0 \), it is easy to see that
\[
P_n^\mu = P(\hat{f}_n(x) \neq -\mu \kappa_n(x), \forall x \in \mathbb{R}),
\]
where the nonrandom \( \kappa_n(x) = (\sum_{i=0}^{n-1} x^i)(\sum_{i=0}^{n-1} x^{2i})^{-1/2} \) are strictly positive and \( \hat{f}_n(x) \) are the normalized polynomials that correspond to \( a_i \) of zero mean. With \( \tilde{P}_n \) for the value of \( P_n \) when coefficients \( \{-a_i\} \) are used instead of \( \{a_i\} \), it is easy to see that
\[
P_n^\mu = P_n - \mu \kappa_n + \tilde{P}_n \mu \kappa_n.
\]
Consequently, we may and shall assume without loss of generality that \( \mu > 0 \), proving only that \( P_n - \mu \kappa_n = n^{-b/2+o(1)} \). Observe that \( \kappa_n(1) = \sqrt{n}, \kappa_n(-1) = 1/\sqrt{n} \) and if \( |x| \neq 1 \), then
\[
\kappa_n(x) = \kappa_n(x^{-1}) = \kappa_n(-x)^{-1} = \frac{(1 + x)(1 - x^n)}{(1 - x)(1 + x^n)}^{1/2}.
\]

License or copyright restrictions may apply to redistribution; see http://www.ams.org/journal-terms-of-use
Moreover, there exists $c = c(\mu) > 0$ such that for all $n$ large enough,
\begin{equation}
\mu \kappa_n(x) \geq n^{-c/8} + \frac{c}{\sqrt{1-x}} \quad \forall x \in [0, 1 - n^{-1}].
\end{equation}

For an upper bound on $P_{n, -\mu \kappa_n}$ let $\mathcal{I}_- = [-1, -1 + 0.5 n^{-c}]$ be the subset of $\mathcal{I}$ of Section 5.3 near the point $-1$ and let $\mathcal{V}_- = \mathcal{I}_3 \cup \mathcal{I}_4$ be the (corresponding) subset of $\mathcal{V}$ of Section 4. It is easy to check that
\begin{equation}
\sup\{\kappa_n(x) : x \in \mathcal{I}_-\} \leq c_1 n^{-c/2}
\end{equation}
for some $c_1 < \infty$ and all $n$. Hence, applying the arguments of Section 5.3 followed by those of Section 4 with $\mathcal{I}$ and $\mathcal{V}$ replacing $\mathcal{I}_-$ and $\mathcal{V}_-$, respectively, results in the stated upper bound $n^{-b/2 + o(1)}$. Turning to prove the corresponding lower bound on $P_{n, -\mu \kappa_n}$, let $\mathcal{I}_+ = [1 - 0.5 n^{-c}, 1]$ denote the subset of $\mathcal{I}$ near the point +1. It follows from (6.4) that $\rho_n$ of (5.6) is zero for $\gamma_n = -\mu \kappa_n$, allowing for the use of $r_n = n^{-1}$ and $\xi_n(x) = -\mu x^n \sigma_n(x) \kappa_n(x) \leq 0$ in (5.8). We then deal with the terms $Q_2$, $Q_3$ and $Q_4$ as in Section 5. For the dominant term $Q_1$, instead of (5.9) we have in view of (6.2) that
\begin{equation}
Q_1 \geq P\left(\hat{f}_n^b(x) > n^{-c/8}, \quad \forall x \in [-1,0] \cup [1 - \frac{1}{n}], \quad \hat{g}_n^b(x) > n^{-c/8}, \quad \forall x \in [0,1 - \frac{1}{n}] \right) - 2n^{-3}
\end{equation}
where $n' = n - 2m = n(1 + o(1))$. By Slepian’s lemma, similarly to (5.11) we see that
\begin{align}
Q_1 &\geq P\left(\hat{f}_n^b(x) > -\frac{c}{\sqrt{1-x}}, \quad \forall x \in [0,1 - \frac{1}{n'}] \right)^2 \quad P\left(\hat{g}_n^b(x) > 1 \quad \forall x \in [1 - \frac{1}{n'}, 1] \right)^2 \\
&= (A_n)^2 (B_n')^2 (C_n')^2.
\end{align}

The sequence $C_n'$ is bounded away from zero by Lemma 2.4. Moreover, it is shown in Section 5.3 that $B_n \geq n^{-b/4 + o(1)}$. In view of (6.3) and (6.4), it thus suffices to show that the sequence $A_n$ is bounded below by some $A_{\infty} > 0$ in order to conclude that
\begin{equation}
P_n \geq P_{n, -\mu \kappa_n} \geq n^{-b/2 + o(1)}
\end{equation}
and complete the proof of part b) of Theorem 1.2. To this end, recall that the function $\sqrt{(1 - x \vee y)/(1 - x \wedge y)}$ in the right side of (3.3) is the covariance of the process $W_{1-x}/\sqrt{1-x}$. Consequently, we have by (3.3) and Slepian’s lemma that
\begin{equation}
A_n \geq P(W_{1-x} > -c, \forall x \in [0,1 - n^{-1}]) \geq P\left(\inf_{0 \leq x \leq 1} W_x > -c \right) = A_{\infty} > 0,
\end{equation}
as needed.

\section{Upper bound for Theorem 1.2}

Fixing small $\delta > 0$ and integers $k_n = o(\log n/\log \log n)$, it suffices for the upper bound in Theorem 1.2 to provide an $n^{-(1-2\delta)b+o(1)}$ upper bound on the probability $q_{n,k}$ such that $f(x) = f_{n+1}(x)$ has at most $k = k_n$ zeros in the set $V = \bigcup_{i=1}^{J_1} \mathcal{I}_i$ of Section 4. To this end, let $x = \theta_i (1 - e^{-t})$ within $\mathcal{I}_i$, $i = 1, 2, 3, 4$, where $\theta_i$ is defined in Section 4. With $T = \log n$ cut the range $t \in [\delta T, (1-\delta)T]$ for each $\mathcal{I}_i$ to $T$ intervals of length $(1-2\delta)$ each, denoting by $J_{(i-1)T+1}, \ldots, J_{iT}$ the corresponding
image in $\mathcal{I}_t$. If $f(x)$ has $\ell$ zeros in some $\mathcal{I}_t$, then there must exist $j_1, \ldots, j_\ell$ such that $f(x)$ has a constant sign $s \in \{-1, 1\}$ on each of the “long” subintervals obtained by deleting $J_{(i-1)T+j_1}, \ldots, J_{(i-1)T+j_\ell}$ from $\mathcal{I}_t$. We partition the event that $f(x)$ has at most $k$ zeros in $V$ according to the possible vector $j = (j_1, \ldots, j_k)$ of “crossing indices” among the $4T$ intervals $\{J_t, \ldots, J_{4T}\}$ and the possible signs $s_m \in \{-1, 1\}$ of $f(x)$ on the resulting long subintervals $L_m$, $m = 1, \ldots, k + 4$, within $V$. Let

$$q_{n,s,j} = P\left(\min_{m=1}^{k+4}\inf_{x \in L_m} s_m f(x) > 0\right),$$

for $s = (s_1, \ldots, s_{k+4})$. Since

$$q_{n,k} \leq \sum_j \sum_s q_{n,s,j},$$

and the number of choices of $j$ and $s$ is at most $2^{k+4}(4T)^k = n^{o(1)}$, it suffices to show that

$$(7.1) \quad \max_{s,j} q_{n,s,j} \leq n^{-(1-2\delta)b+o(1)}.$$

Applying the coupling of $(f_k, g_k)$ and $(f^b_k, g^b_k)$ as provided in (5.4) and (5.5) for $t = n^{\delta/4}$ and $p = 16/\delta$, we see that for all $j$ and $s$,

$$(7.2) \quad q_{n,s,j} \leq P\left(\min_{m=1}^{k+4}\inf_{x \in L_m} s_m f^b_{n+1}(x) > -n^{-\delta/8}\right) + cn^{-3} \leq q_{n,s,j}^b + cn^{-3},$$

where $c < \infty$ depends on $\delta$ but is independent of $j$, $s$ and $n$. Thus, the proof reduces to the Gaussian case.

Suppose first that $n$ is even. The covariance function of $s_m f^b_{n+1}(x)$ on $V' = \bigcup_m L_m$ is then given by $s_m c_{n+1}(x,y)$ for $x \in L_m$ and $y \in I_t$. Since $c_{n+1}(x,y) > 0$ for all $x,y$, it follows by Slepian’s lemma that per choice of $j$, the probability $q^b_{n,s,j}$ is maximal when $s_m = 1$ for all $m$. In case $n$ is odd, note that $f^b_{n+1}(x) = \sigma_n(x) f^b_n(x) + b_n x^n$ and

$$|x|^n \leq 2n^{-\delta/2} \sigma_n(x) \quad \forall x \in V.$$

Consequently, for all $j$ and $s$,

$$(7.3) \quad q^b_{n,s,j} \leq P(|b_n| \geq n^{\delta/4}) + P\left(\min_{m=1}^{k+4}\inf_{x \in L_m} s_m f^b_n(x) > -2n^{-\delta/8}\right).$$

With $n - 1$ even, continuing as before, we see that the right-most term in (7.3) is maximal when $s_m = 1$ for all $m$. In conclusion, it suffices to consider

$$q^b_{n,j} = P\left(\inf_{x \in V'} f^b_{n+1}(x) > -2n^{-\delta/8}\right),$$

for $n$ even. Applying the arguments of (4.2), (4.4) and (4.5) with $\gamma_n(x) \equiv -2n^{-\delta/8}$ on the subset $V'$ of $V$, we find that

$$(7.4) \quad q^b_{n,j} \leq \varepsilon^{-n^{\delta/4}/2} + \prod_{i=1}^4 P\left(\sup_{t \in T_i} Y_i \leq \varepsilon_T\right),$$

where $Y_i$ is the stationary Gaussian process of Lemma 2.2 and for $i = 1, \ldots, 4$ the set $T_i \subset [\delta T, (1 - \delta)T]$ is the image of $V' \cap T_i$ under the transformation $t = -\log(1 - \theta_t(x))$. Since $\tau \mapsto R_\nu(\tau)$ is monotonically decreasing on $[0, \infty)$, it follows by Slepian’s lemma that $P(\sup_{t \in T_i} Y_i \leq \varepsilon_T)$ is maximal per fixed size of $T_i$ when the latter set is an interval, that is, when the $J_{j_i}$ are all at one end of $\mathcal{I}_t$ for each
8. Proof of Theorem 1.2

In view of the upper bound $q_{n,k} \leq n^{-b+o(1)}$ of Section 7, it suffices to show that $p_{n,k} \geq n^{-b-o(1)}$, in order to complete the proof of Theorem 1.2.

Since $a_i$ are of zero mean and positive variance, the support of their law must intersect both $(0, \infty)$ and $(-\infty, 0)$. Consequently, there exist $\beta < 0 < \alpha$ such that $P(|a_i - \alpha| < \epsilon) > 0$ and $P(|a_i - \beta| < \epsilon) > 0$ for all $\epsilon > 0$. Replacing $\{a_i\}$ by $\{-a_i\}$ does not affect the number of zeros of $f_{n+1}(x)$. Hence, we may and shall assume without loss of generality that $|\alpha| \geq |\beta|$. Let $s \geq 4$ be an even integer such that $\alpha + (s - 1)\beta < 0$. Define

$$Q(x) = \beta x^{s-1} + \sum_{i=0}^{s-2} \alpha x^i, \quad R(x) = \alpha + \sum_{i=1}^{s-1} \beta x^i,$$

and note that

$$Q(x) > 0 \quad \forall |x| \leq 1, \quad R(1) < 0 < R(-1).$$

8.1. Proof for $k$ and $n$ even. Suppose that $k$ and $n$ are even. After $k, s, \alpha, \beta$ are fixed, we shall choose $\delta > 0$ sufficiently small, then a large enough integer $r = r(\delta)$, followed by a small enough positive $\epsilon = \epsilon(\delta, r)$, all of which are independent of $n$. Let $r_i$ denote the multiple of $s$ nearest to $r^i$, for $i = 1, \ldots, k$, and let $\rho_n := \max\{5/p_n, (\log n)^{-1/2}\}$ for $p_n \uparrow \infty$ such that $E|a_i|^\rho_n \leq n$ (these choices are slightly different from the ones made in Section 7). Let $m = m_n$ be the multiple of $s$ nearest to $2r_k\rho_n \log n/|\log(1-\delta)|$ and define the polynomials

$$B(x) = \sum_{i=0}^{m-1} b_ix^i := (1 + x^s + x^{2s} + \cdots + x^{r_1-s})Q(x) + (x^{r_1} + x^{r_1+s} + \cdots + x^{r_2-s})R(x) + (x^{r_2} + x^{r_2+s} + \cdots + x^{r_3-s})Q(x) + (x^{r_3} + x^{r_3+s} + \cdots + x^{r_4-s})R(x) + \cdots + (x^{r_k} + x^{r_k+s} + \cdots + x^{m-s})Q(x),$$

$$C(X) = \sum_{i=0}^{m-1} c_i X^i := (1 + X^s + X^{2s} + \cdots + X^{m-s})Q(X).$$

Each coefficient $b_i$ of $B(x)$ equals either $\alpha$ or $\beta$. The same holds for each coefficient $c_i$ of $C(X)$. Let $A_i$ denote the event that the following hold:

A1 $|a_i - b_i| < \epsilon$ for $i = 0, 1, \ldots, m - 1.$
A2 $|a_{n-i} - c_i| < \epsilon$ for $i = 0, 1, \ldots, m - 1.$
A3 $a_m + a_{m+1}x + \cdots + a_{n-m}x^{n-2m} > n^{-1/4}\sigma_{n-2m+1}(x)$ for all $x \in \mathbb{R}.$
A4 $|a_i| < n^{\rho_n}$ for $i = 0, 1, \ldots, n.$

Most of our work shall be to show that the polynomial $B(x)$ has the required behavior in terms of zeros for $|x| \leq (1-\delta)^{1/r_k}$. Conditions A1 and A4 ensure that $f(x)$ is close enough to $B(x)$ on this interval so as to have exactly $k$ simple zeros there. The condition A3 precludes additional zeros of $f(x)$ near $\pm 1$. Moreover,
with \( A2 \) and the positivity of \( C(X) \) for \(|X| \leq 1\), we conclude that \( f(x) > 0 \) when \(|x| > 1\).

The stated lower bound on \( p_{n,k} \) is an immediate consequence of the following two lemmas.

**Lemma 8.1.** For any fixed \( \delta > 0 \), \( \epsilon > 0 \) and an integer \( r \), the probability of the event \( A_n \) is at least \( n^{-b-o(1)} \) for even \( n \to \infty \).

**Lemma 8.2.** Suppose the even integer \( k \) is fixed. There exist small enough \( \delta > 0 \), large enough \( r = r(\delta) \) and a small enough \( \epsilon = \epsilon(\delta, r) \) positive, such that for all sufficiently large even \( n \), any polynomial \( f(x) = \sum_{i=0}^{n} a_i x^i \) whose coefficients are in \( A_n \) has exactly \( k \) real zeros, each of which is a simple zero.

**Proof of Lemma 8.1.** Since all coefficients of \( B(x) \) and \( C(x) \) belong to \( \{\alpha, \beta\} \), our choice of \( \alpha \) and \( \beta \) implies that each coefficient condition in \( A1 \) and \( A2 \) is satisfied with probability at least \( c \) for some \( c > 0 \) depending only on \( \epsilon \). The probability that condition \( A3 \) holds is \( P_{n',\gamma_{n'}} \) of Theorem 1.3 for \( n' = n - 2m + 1 \) odd and \( \gamma_{n'}(x) \equiv n^{-1/4} \) that satisfy the assumptions of this theorem. Consequently, condition \( A3 \) holds with probability of at least \( (n')^{-b-o(1)} = n^{-b-o(1)} \). Since conditions \( A1 \), \( A2 \) and \( A3 \) are independent, the probability that all of them hold is at least

\[
(8.2) \quad c^{2m(n')^{-b+o(1)}} = n^{-b-o(1)}.
\]

(Recall that \( \rho_n \to 0 \), hence also \( m_n/\log n \to 0 \).) By Markov’s inequality and the choice of \( \rho_n \), the probability that condition \( A4 \) fails for a given \( i \) is at most \( n^{-4} \). Hence the probability that this condition fails for any \( i \) in the range \( 0 \leq i \leq n \) is at most \( O(n^{-3}) \). Since \( b \leq 2 \), imposing condition \( A4 \) does not affect the \( n^{-b-o(1)} \) lower bound of \( (8.2) \). \( \square \)

**Proof of Lemma 8.2.** The proof of the lemma is divided into three steps.

**Step 1:** For \( \delta > 0 \) sufficiently small, \( r > (\log \delta)/(\log(1 - \delta)) \) sufficiently large, \( \epsilon > 0 \) sufficiently small and all large even integers \( n \), each polynomial \( f(x) \) with coefficients in \( A_n \) has exactly \( k \) simple zeros in \([0, 1]\).

**Step 2:** Under the same conditions on the parameters, \( f(x) > 0 \) on \([-1, 0] \).

**Step 3:** \( g(X) = X^n f(X^{-1}) > 0 \) on \((-1, 1) \).

**Step 1.** Fixing \( f(x) \) as above, observe that the zeros of \( f(x) \) in \((0, 1) \) are the same as those of \( F(x) := (1 - x^s)f(x) \), so it suffices to prove that:

- \( F(x) > 0 \) for \( x \in [0, \delta^{1/r_1}] \)
- \( F'(x) < 0 \) for \( x \in [\delta^{1/r_1}, (1 - \delta)^{1/r_1}] \)
- \( F(x) < 0 \) for \( x \in [(1 - \delta)^{1/r_1}, \delta^{1/r_2}] \)
- \( F'(x) > 0 \) for \( x \in [\delta^{1/r_2}, (1 - \delta)^{1/r_2}] \)
- \( F(x) > 0 \) for \( x \in [(1 - \delta)^{1/r_2}, \delta^{1/r_3}] \)
- \( F'(x) < 0 \) for \( x \in [\delta^{1/r_3}, (1 - \delta)^{1/r_3}] \)

\vdots

- \( F'(x) > 0 \) for \( x \in [\delta^{1/r_k}, (1 - \delta)^{1/r_k}] \)
- \( F(x) > 0 \) for \( x \in [(1 - \delta)^{1/r_k}, 2^{-1/m}] \)
- \( f(x) > 0 \) for \( x \in [2^{-1/m}, 1] \)

Indeed, the sign changes in \( F(x) \) force at least one real zero in each of the \( k \) gaps between the intervals on which \( F \) is guaranteed positive or negative, and the monotonicity of \( F'(x) \) on these gaps guarantees that each of them contains exactly
one zero and that the zero is simple. Note also that $m = m_n \to \infty$, so per choice of $\delta > 0$ all the intervals of $x$ above are nonempty as soon as $r$ is large enough.

Recall that our choice of $m = m_n$ is such that for any $l < \infty$,

$$m^l n^\rho (1 - \delta)^{m/\rho} \to 0.$$  

Consequently, by conditions $\mathbf{A1}$ and $\mathbf{A4}$ of $A_n$, there exists $c(r, \delta)$ finite, such that for all $\epsilon > 0$, $n$ large enough and $|x| \leq (1 - \delta)^{1/r}$,

$$|F(x) - (1 - x^*)B(x)|$$

$$\leq (1 - x^*) \left[ \epsilon (1 + |x| + \cdots + |x|^{m-1}) + n^\rho (|x|^m + \cdots + |x|^n) \right]$$

$$\leq (1 - |x|)^{-1} \left( \epsilon + n^\rho x^m \right) \leq c(r, \delta) \epsilon.$$

Fix $M$ such that $|Q(x)| \leq M$ and $|R(x)| \leq M$ for all $x \in [0,1]$. By definition of $B(x)$,

$$Q(x) + \sum_{\ell=1}^k (-1)^\ell (Q(x) - R(x)) x^{\ell r} - Q(x)x^m.$$  

Suppose $x \in [0, \delta^{1/r_1}]$. Then, each $x^{\ell r}$ and $x^m$ is at most $\delta$, so

$$(1 - x^*) B(x) \geq Q(x) - (2k+1)M\delta.$$  

Therefore, for all $\delta$ sufficiently small, the positivity of $Q(x)$ on $[0,1]$ (see $\mathbf{S1}$) implies that $(1 - x^*) B(x) \geq \eta$ for some $\eta > 0$ independent of $n$, and all $x \in [0, \delta^{1/r_1}]$. For $\epsilon > 0$ small enough, this in turn implies the positivity of $F(x)$ on this interval (see $\mathbf{S4}$).

Suppose $x \in [(1 - \delta)^{1/r_1}, \delta^{1/r_1+1}]$ for some $j \in \{1, 2, \ldots, k - 1\}$. Then, $x^m \leq x^{\ell r} \leq \delta$ for all $\ell > j$ and $x^{\ell r} \in [1 - \delta, 1]$ for all $\ell \leq j$. In view of the identity

$$Q(x) + \sum_{\ell=1}^j (-1)^\ell (Q(x) - R(x)) = Q(x)1_j \text{ is even } + R(x)1_j \text{ is odd}$$

and $\mathbf{S5}$, it follows that for all $x$ as above,

$$|(1 - x^*) B(x) - [Q(x)1_j \text{ is even } + R(x)1_j \text{ is odd}]| \leq (2k+1)M\delta.$$  

For $\delta$ small enough, the error $(2k+1)M\delta$ is at most $\min(Q(1), -R(1))/3$. Once $\delta$ is chosen, taking $r$ sufficiently large guarantees that $Q(x) \geq Q(1)/2$ and $R(x) \leq R(1)/2$ for all $x \in [(1 - \delta)^{1/r_1}, 1]$. Since $Q(1)$ is positive and $R(1)$ is negative (see $\mathbf{S4}$), we conclude that there exists $\eta > 0$ independent of $n$ such that $(-1)^j (1 - x^*) B(x) \geq \eta$ for all $n$ large enough and all $x \in [(1 - \delta)^{1/r_1}, \delta^{1/r_1+1}]$, $j = 1, \ldots, k - 1$. In view of $\mathbf{S4}$, for all $\epsilon > 0$ small enough, $(-1)^j F(x)$ is then positive throughout the interval $x \in [(1 - \delta)^{1/r_1}, \delta^{1/r_1+1}]$, as needed.

Suppose $x \in [(1 - \delta)^{1/r_1}, 2^{-1/m}]$. Then, $x^{\ell r} \in [1 - \delta, 1]$ for all $\ell \leq k$ and $x^m \leq 1/2$. With $k$ even, it follows from $\mathbf{S5}$ and $\mathbf{S6}$ that

$$(1 - x^*) B(x) \geq \frac{1}{2} Q(x) - 2kM\delta.$$  

So, when $\delta > 0$ is small enough, then for some $\eta > 0$ independent of $n$, it holds that $(1 - x^*) B(x) \geq \eta$ for all $n$ large enough and all $x \in [(1 - \delta)^{1/r_1}, 2^{-1/m}]$. Recall that

$$(1 - x^*) x^m (a_m + a_{m+1} x + \cdots + a_{n-m} x^{n-2m}) \geq 0$$

as above.
by condition A3. So, while \( F(x) - (1 - x^s)B(x) \) is no longer negligible as in (8.4), the positivity of the expression in (8.7) results in
\[
F(x) - (1 - x^s)B(x) \geq -(1 - x^s)(e + \sum_{j=1}^{m-1} j^{|x|^m} + m(a + \epsilon)|x|^{n-m}) \\
\geq -c(\delta, \epsilon)\epsilon
\]
for some finite \( c(\delta, \epsilon) \), all \( \epsilon > 0 \) and large enough \( n \). (This is because \( m_n = o(\log n) \), so \( m_n x^{n-m_n} \to 0 \) as \( n \to \infty \), uniformly on \( x \in [(1-\delta)^{1/r_k}, 2^{-1/m}] \).) Consequently, when \( \epsilon > 0 \) is small enough, the uniform positivity of \( (1 - x^s)B(x) \geq \eta > 0 \) results in the positivity of \( F(x) \) for \( x \in [(1-\delta)^{1/r_k}, 2^{-1/m}] \).

Suppose \( x \in [2^{-1/m}, \delta^{1/n}] \). Using the decomposition \( f = f^L + f^M + f^H \) as in (8.7), note that by condition A1
\[
f^L(x) \geq B(x) - \epsilon \sum_{i=0}^{m-1} |x|^i \geq (x^{r_k} + x^{r_k+s} + \cdots + x^{m-s})Q(x) - r_k M - \epsilon m
\]
\[
\geq \left( \frac{m - r_k}{2} \right) Q(x) - r_k M - \epsilon m.
\]
Note that \( f^M(x) \geq 0 \) by condition A3 and
\[
|f^H(x)| \leq m(a + \epsilon)|x|^{n-m} \leq m(2\alpha)\delta^{1-m/n} \leq 2m\alpha \delta^{1/2}
\]
by condition A2. Since \( m_n \to \infty \) and \( Q(x) \) is strictly positive, we see by combining the above that if \( \delta \) and \( \epsilon \) are small enough then for all \( n \) large enough the “main” term \( m_n Q(x)/(2s) \) dominates, so \( f(x) > 0 \) for all \( x \in [2^{-1/m}, \delta^{1/n}] \).

Suppose \( x \in [\delta^{1/n}, 1] \). In this case, by condition A3,
\[
(8.8) \quad f^M(x) \geq x^m n^{-1/4} \sigma_n - 2m + 1 \geq n - 1/8
\]
as \( n \to \infty \). Condition A1 implies that \( |f^L(x)| \leq (\alpha + \epsilon) n \), whereas condition A2 implies that \( |f^H(x)| \leq (\alpha + \epsilon) n \). Since \( m = o(\log n) \), we conclude that \( f(x) > 0 \) for large \( n \) and all \( x \in [\delta^{1/n}, 1] \).

We turn now to dealing with the sign of \( F'(x) \) in the gaps \( [\delta^{1/r_j}, (1 - \delta)^{1/r_j}] \) for \( j = 1, \ldots, k \). To this end, first note that
\[
F'(x) = \frac{d}{dx} [(1 - x^s)B(x)] + e(x),
\]
where by conditions A1 and A4, there exists \( c(\delta, \epsilon) \) finite, such that for all \( \epsilon > 0 \), \( n \) large enough and \( x \in [0, (1 - \delta)^{1/r_k}] \),
\[
|e(x)| \leq |s x^{s-1} |e(1 + x + \cdots + x^{m-1}) + n^p (x^m + x^{m+1} + \cdots + x^n)| \\
+ |1 - x|^p |e(1 + 2x + \cdots + (m-1)x^{m-2}) + n^p (x^m + x^{m+1} + \cdots + nx^{n-1})|
\]
(8.9) \[
\leq s (1 - x)^{-1} (\epsilon + n^p x^m) + (1 - x)^{-2} (\epsilon + n^p m x^{m-1}) \leq c(\delta, \epsilon)\epsilon
\]
(see (8.3) and (8.4)). Next, using (8.5), we obtain
\[
(8.10) \quad \frac{d}{dx} [(1 - x^s)B(x)]
\]
\[
= Q'(x) + \sum_{\ell=1}^{k} (-1)^\ell \left( [Q'(x) - R'(x)]x^{r_\ell} + (Q(x) - R(x))r_\ell x^{r_\ell-1} \right) - o(1).
\]
(The \(o(1)\) denotes two terms involving \(x^n\), which by (8.3) converge to 0 uniformly on \(x \in [0, (1 - \delta)^{1/r_1}]\).) The sum of the terms involving \(Q'(x)\) or \(R'(x)\) in (8.10) is at most \((2k + 2)M'\), where \(M'\) is such that \(|Q'(x)| \leq M'\) and \(|R'(x)| \leq M'\) for all \(x \in [0, 1]\). Per fixed \(\delta > 0\), if \(r\) is sufficiently large then \(Q(x) - R(x) \geq \eta\) for some \(\eta > 0\) and all \(x \in [\delta^{1/r_1}, 1]\) (see (8.4)). We claim that if \(x \in [\delta^{1/r_1}, (1 - \delta)^{1/r_j}]\) for some \(j \in \{1, 2, \ldots, k\}\), then the term \(h_j := (-1)^j(Q(x) - R(x))r^{-1}_{j}x^{r_j-1}\) dominates the right hand side of (8.10) for all \(r\) large enough. Indeed, \(|h_j| \geq \eta \delta r_j\) for all \(x \in [\delta^{1/r_j}, (1 - \delta)^{1/r_j}]\), whereas for such \(x\) we have that \(|h_\ell| \leq 2Mr_{\ell-1}\) when \(\ell < j\) and \(|h_\ell| \leq 2Mr_\ell(1 - \delta)^{(r_{\ell+1}-1)/r_j}\) when \(\ell > j\). Since \(r_\ell = r^\ell(1 + o(1))\), combining the above we see that for all large enough \(r\),

\[
(-1)^j \frac{d}{dx}[(1 - x^s)B(x)] \\
\geq \frac{\eta}{2} \delta r^j - 3MK(r^j + r^k(1 - \delta)^{\sqrt{T}}) - (2k + 2)M' - o(1) \geq \frac{\eta}{3} \delta r^j.
\]

By (8.3) we then get that for small enough \(\epsilon > 0\), \((-1)^jF'(x)\) also is positive in the \(j\)-th gap.

This completes Step 1.

**Step 2.** As before, define \(F(x) := (1 - x^s)f(x)\). The proof that \(F(x) > 0\) on \([-\delta^{1/r_1}, 0]\) is the same as the proof for \([0, \delta^{1/r_1}]\), now using the positivity of \(Q(x)\) on \([-1, 0]\). For each \(j \in \{1, 2, \ldots, k - 1\}\), the analysis for \([-\delta^{1/r_j+1}, -(1 - \delta)^{1/r_j}]\) is the same as that for \([1 - \delta^{1/r_j}, \delta^{1/r_j+1}]\), the only difference is that \(Q(x)\) and \(R(x)\) are both positive near \(-1\) (whereas they have opposite signs near \(1\)), so the result is that \(F(x) > 0\) on these intervals, independent of the parity of \(\ell\). The analyses for \([-2^{-1/m}, -(1 - \delta)^{1/r_k}]\) for \([-1, -2^{-1/m}]\) are the same as for the symmetric intervals on the positive side.

To complete the proof that \(f(x) > 0\) on \([-1, 0]\), it remains to show that \(F(x) > 0\) on each gap \([-1 - \delta^{1/r_j}, -\delta^{1/r_j}]\) for \(j = 1, \ldots, k\). By (8.3), it suffices to show that on such an interval \((1 - x^s)B(x) \geq \eta\) for some \(\eta > 0\), independent of \(\epsilon\) and \(n\). On the \(j\)-th such interval, \(x^m \leq x^r \leq \delta\) for all \(\ell > j\), whereas if \(r\) is sufficiently large, then \(1 \geq x^r \geq \delta^{r_j/r_j} \geq (1 - \delta)\) for all \(\ell < j\). Hence, it follows from (8.5) and (8.6) that

\[
(8.11) \quad \|(1 - x^s)B(x) - [t(x)Q(x) + (1 - t(x))R(x)]\| \leq (2k - 1)M\delta,
\]

where \(t(x) = 1 - \eta r_j\) for \(j\) even, and \(t(x) = x^r_j\) otherwise. Let \(\eta = \min\{Q(-1), R(-1)\} < 4 > 0\), and take \(\delta\) small enough such that \(2k - 1)M\delta < \eta\). Since \(t(x) \in [0, 1]\), if \(r\) is large enough such that \(\min\{Q(x), R(x)\} > 2\eta\) for all \(x \in [-1, -\delta^{1/r_j}]\), then (8.11) implies that \((1 - x^s)B(x) \geq \eta\) for all \(x \in [-1 - \delta^{1/r_j}, -\delta^{1/r_j}]\), \(j = 1, \ldots, k\). The positivity of \(F(x)\) for small \(\epsilon\) and large \(n\) follows by (8.4).

**Step 3.** To complete the proof of Lemma 8.2 it suffices to show that \(g(X) := X^n f(X^{-1})\) is positive on \((-1, 1)\). For \(\epsilon < \alpha\), conditions A1, A2 and A3 result in

\[
(8.12) \quad \frac{g(X)}{X^n} \geq C(X) - (\epsilon + 2\alpha X^{-m}) \sum_{i=0}^{m-1} |X|^i + X^m n^{-1/4} \sigma_{n-m+1}(X),
\]

for all \(|X| \leq 1\). Since \((1 - X^s)C(X) = (1 - X^m)Q(X)\), we see that for \(n\) large enough and all \(|X| \leq 2^{-1/m}\),

\[
(1 - X^s)g(X) \geq (1 - X^m)Q(X) - (\epsilon + 4\alpha x^{-n/m}) \sum_{i=0}^{m-1} |X|^i \geq \frac{1}{2} Q(X) - 2\kappa
\]
is positive for $\epsilon < \eta/(8s)$, where $\eta = \min\{Q(x), |x| \leq 1\} > 0$. Since $C(X) \geq \frac{\sigma}{2\pi} Q(X)$ when $|X| \in [2^{-1/m}, \delta^{1/n}]$, it follows from (8.12) that

$$g(X) \geq m \left[ \frac{Q(X)}{2s} - \epsilon - 2\alpha \delta^{-m/n} \right]$$

is positive for any such $X$, provided $\epsilon < Q(1)/(8s), 2\alpha \delta^{1/2} < Q(1)/(8s)$ and $n$ is large enough. Finally, for large $n$, if $|X| \in [\delta^{1/n}, 1]$, then $X^m n^{-1/4} \sigma_{n-m+1}(X) \geq n^{1/8}$ (see (8.8)). Since $m = o(\log n)$, the positivity of $g(X)$ for such $X$ is a direct consequence of (8.12).

8.2. Proof for $k$ and $n$ odd. In this section we sketch the modifications to the argument of the previous section that are required for the case where $k$ and $n$ are odd. We will specify an event occurring with probability at least $n^{-b-o(1)}$ that forces $k-1$ simple zeros in $(0, 1)$, one simple zero in $(-\infty, -1)$, and no other real zeros. Fix positive $\delta$, integer $r$ and $\epsilon > 0$, and define $r_i, \rho = \rho_n$ and $m = m_n$ as in Section 8.1. Define the polynomials

$$B(x) = \sum_{i=0}^{m-1} b_i x^i := (1 + x^s + x^{2s} + \cdots + x^{r_1 - s})Q(x)$$

$$+ (x^{r_1} + x^{r_1+s} + \cdots + x^{r_2-s})R(x)$$

$$+ (x^{r_2} + x^{r_2+s} + \cdots + x^{r_3-s})Q(x)$$

$$+ (x^{r_3} + x^{r_3+s} + \cdots + x^{r_4-s})R(x)$$

$$\cdots + (x^{r_k-1} + x^{r_k-1+s} + \cdots + x^{m-s})Q(x),$$

$$C(X) = \sum_{i=0}^{m} c_i X^i := (1 + X^s + X^{2s} + \cdots + X^{r_1 - s})Q(X)$$

$$+ \alpha X^{r_1} + X(X^{r_1} + X^{r_1+s} + \cdots + X^{m-s})Q(X)$$

the coefficients of which are in $\{\alpha, \beta\}$. Let $\mathcal{B}_n$ denote the event that the following hold:

- **B1** $|a_i - b_i| < \epsilon$ for $i = 0, 1, \ldots, m - 1$.
- **B2** $|a_{n-i} - c_i| < \epsilon$ for $i = 0, 1, \ldots, m$.
- **B3** $\alpha_m + a_{m+1}x + \cdots + a_{n-m-1}x^{n-2m-1} > n^{-1/4} \sigma_{n-m}(x)$ for all $x \in \mathbb{R}$.
- **B4** $|a_i| < n^\rho$ for $i = 0, 1, \ldots, n$.

Note that the degree of $C(X)$ is one larger than in Section 8.1. This ensures that the “middle polynomial” in condition 8.3 has even degree, so that Theorem 1.3 applies to it. Hence, similarly to the proof of Lemma 8.1, one has that the event $\mathcal{B}_n$ occurs for odd $n$ with probability exceeding $n^{-b-o(1)}$.

For all small enough $\delta > 0$, large enough $r$ and small enough $\epsilon$, the argument of the proof of Lemma 8.2 using the shape of $B(x)$, shows that if the coefficients of $f(x)$ are in $\mathcal{B}_n$, then $f(x)$ has exactly $k-1$ zeros in $(0, 1)$, all simple, and no zeros in $[-1, 0]$. We next prove that the function $F(X) := (1 - X^s)X^n f(1/X)$ satisfies:

- $F(X) > 0$ for $X \in (0, 1)$
- $F(X) > 0$ for $X \in [-\delta^{1/r_1}, 0)$
- $F'(X) > 0$ for $X \in [-1, -\delta^{1/r_1}]$
- $F(X) < 0$ for $X \in [-2^{-1/m}, -(1 - \delta)^{1/r_1}]$
- $F(X) < 0$ for $X \in (-1, -2^{-1/m})$
These will imply that \( f(x) \) has a simple zero in \((-\infty, -1)\), and no other zeros with \(|x| > 1\). Together with the \( k - 1 \) simple zeros in \([0, 1]\), this will bring the total number of zeros to \( k \).

First, a proof analogous to that of (8.4) shows that there exists \( c(r, \delta) \) finite, such that for \(|X| \leq (1 - \delta)^{1/r_1} \),

\[
(8.13) \quad |F(X) - (1 - X^s)C(X)| \leq c(r, \delta)\epsilon.
\]

The analogue of (8.5) is

\[
(8.14) \quad (1 - X^s)C(X) = (1 - X^{r_1} + X^{r_1+1} - X^{m+1})Q(X) + \alpha X^{r_1}(1 - X^s).
\]

Suppose \( X \in [0, (1 - \delta)^{1/r_1}] \). Then (8.14) implies

\[
(1 - X^s)C(X) \geq (1 - X^{r_1})Q(X) \geq \delta Q(X) > c(r, \delta)\epsilon
\]

if \( \epsilon \) is small enough, so \( F(X) > 0 \) by (8.13).

Suppose \( X \in [-\delta^{1/r_1}, 0] \). Then (8.13) implies

\[
(1 - X^s)C(X) \geq (1 - 3\delta)Q(X)
\]

so \( F(X) > 0 \) by (8.13) assuming suitable \( \delta \) and \( \epsilon \).

Suppose \( X \in [-\delta^{1/r_1}, -\delta^{1/r_1}] \). The analogue of (8.9) and (8.10) is

\[
\left| F'(X) - \frac{d}{dX} ((1 - X^s)C(X)) \right| \leq c(\delta, r)\epsilon
\]

and, with \( r_1, s \) even,

\[
\frac{d}{dX} ((1 - X^s)C(X)) = (1 - X^{r_1} + X^{r_1+1}) Q'(X)
\]

\[
+ \left[ -r_1 X^{r_1-1} + (r_1 + 1) X^{r_1} \right] Q(X)
\]

\[
+ \alpha r_1 X^{r_1-1}(1 - X^s) - \alpha s X^{r_1+s-1} - o(1)
\]

\[
\geq -3M' + r_1 \delta Q(X) - \alpha r_1 (1 - \delta^{s/r_1}) - o(1)
\]

\[
\geq (r_1 \delta/2)Q(X),
\]

in which the last inequality holds for \( r \) sufficiently large. Hence for \( \epsilon \) small enough, \( F'(X) \) will be positive.

Suppose \( X \in [-2^{-1/m}, -(1 - \delta)^{1/r_1}] \). Then, for \( r \) sufficiently large, \( 1 - X^{r_1} + X^{r_1+1} - X^{m+1} \leq -(1/2 - 3\delta)/2 \) and \( \alpha X^{r_1}(1 - X^s) = O(s/r_1) \). For \( \delta \) small and \( r \) large (8.14) thus implies that

\[
(1 - X^s)C(X) \leq -(1/2 - 3\delta)Q(X)/2 + O(s/r_1) \leq -Q(X)/8.
\]

Although (8.13) is no longer valid, we may apply B3 to deduce

\[
F(X) - (1 - X^s)C(X) \\
\leq \epsilon s + (1 - X^s)(a_m X^{n-m} + a_{m+1} X^{n-m-1} + \ldots + a_{n-m-1} X^{m+1}) \\
+ m(\alpha + \epsilon)X^{n-m+1} \\
\leq \epsilon s + m(\alpha + \epsilon)2^{-(n-m+1)/m} \leq 2\epsilon s
\]

since \( m2^{-n/m} \rightarrow 0 \). Hence \( F(X) < 0 \) if we first take \( \delta \) small then \( r \) large and finally \( \epsilon \) small.

Similarly, for \( r \) large enough, if \( X \in [(1 - \delta)^{1/r_1}, 2^{-1/m}] \), then

\[
(1 - X^s)C(X) \geq (1 - X^{m})Q(X) \geq Q(X)/3
\]
and
\[ F(X) - (1 - X^*)C(X) \geq -\varepsilon s - m(\alpha + \varepsilon)X^{n-m+1} \geq -2\varepsilon s , \]
implying that \( F(X) > 0 \) in this interval.

Both the proof that \( F(X) > 0 \) on \([2^{-1/m}, 1]\) and the proof that \( F(X) < 0 \) on \((-1, -2^{-1/m}]\) parallel the proof in Section 3.1 that \( f(x) > 0 \) for \( x \in [2^{-1/m}, 1] \). □

9. PROOF OF PROPOSITION 1.5

In view of the upper bound \( q_{n,k} \leq n^{-b+o(1)} \) of Section 4 it suffices to provide a lower bound on the probability of the event considered in Proposition 1.5. To this end, partitioning and shrinking the \( U_i \), if necessary, we may assume that \( m_1 = \ldots = m_k = 1 \), and that the closures of the \( U_i \) avoid both 1 and -1. Let \( \delta \in (0, 1/3) \) then be such that each of the \( U_i \) is contained either in \((-1 + \delta, 1 - \delta)\) or its image under the map \( \text{inv}(x) = x^{-1} \). Let \( r \) be the number of \( U_i \) of the former type and \( s = k - r \) the number of those of the latter type. Let \( S = (-\eta/2, \eta/2) \) for \( \eta > 0 \) as in the statement of the proposition. Fix the polynomials \( B(x) = \sum_{i=0}^b b_i x^i \in S[x] \) and \( C(X) = \sum_{i=0}^s c_i X^i \in S[X] \) with coefficients in \( S \), such that \( B(x) \) has \( r \) real zeros, one in each of the \( U_i \) that are contained in \((-1, 1)\) whereas \( C(X) \) has \( s \) real zeros, one in \( \text{inv}(U_i) \) for each \( U_i \) contained in \((-\infty, -1) \cup (1, \infty) \). Without loss of generality we can set \( b_r > 0 \) and \( c_s > 0 \). Let \( \rho_n = 5/p_n \) for \( p_n \uparrow \infty \) such that \( E|a_i|^p \leq n \) (these differ from the quantities defined in Section 5). Define the even integer \( m = m_n = 2[p_n \log n/\log(1 - \delta)] \) depending on \( n \). For fixed \( \varepsilon \in (0, \eta/11) \), consider the event \( C_n \) that all of the following are satisfied:

**C1** \( |a_i - b_i| < \varepsilon \) for \( 0 \leq i \leq r \), \( |a_{r+i} - 9\varepsilon 1_{\text{even}}| < \varepsilon \) for \( 0 < i < m \).

**C2** \( |a_{n-i} - c_i| < \varepsilon \) for \( 0 \leq i \leq s \), \( |a_{n-s-i} - 9\varepsilon 1_{\text{even}}| < \varepsilon \) for \( 0 < i < m \).

**C3** \( a_{m+i} + a_{m+r + 1}x + \cdots + a_{n-s-m}x^{n-k-2m} > 0 \) for all \( x \in \mathbb{R} \).

**C4** \( |a_i| < n^{\rho} \) for \( 0 \leq i \leq n \).

Proposition 1.5 is an immediate consequence of the following two lemmas.

**Lemma 9.1.** For any fixed \( B(x) \), \( C(X) \) with coefficients in \( S \) and positive \( \varepsilon \) < \( \eta/11 \), the probability of the event \( C_n \) is at least \( n^{-b+o(1)} \).

**Lemma 9.2.** For fixed \( B(x) \) and \( C(X) \), if \( \varepsilon > 0 \) is sufficiently small and \( n \) sufficiently large, then any polynomial \( f(x) = \sum_{i=0}^n a_i x^i \) satisfying the conditions of \( C_n \) has exactly \( k \) real zeros, one in each of the \( U_i \) intervals.

**Proof of Lemma 9.1.** Note that \( P(a \in G) > 0 \) for any open subset \( G \) of \((-\eta, \eta)\) (by our assumption about the support of the law of \( a_i \)). Hence each coefficient condition in C1 and C2 is satisfied with probability at least \( c \) for some \( c > 0 \) depending only on \( B(x) \), \( C(X) \) and \( \varepsilon \). We continue along the lines of the proof of Lemma 5.1 (taking now \( n' = n - k - 2m + 1 \) and \( \gamma_{n'} = 0 \)). □

**Proof of Lemma 9.2.** Our choice of \( \rho = \rho_n \) and \( m = m_n \) guarantees that for any \( l < \infty \), \( m'n^\rho(1 - \delta)^m \rightarrow_{n \rightarrow \infty} 0 \). Consequently, by C1 and C4, for some \( k_0 = k_0(\delta) \), all \( \varepsilon > 0 \), \( n > n_0 \) for some \( n_0 = n_0(\delta, \varepsilon) \) large enough and \( |x| \leq (1 - \delta) \)

\[
|f(x) - B(x)| \leq 10\varepsilon (1 + |x| + \cdots + |x|^{m+r-1}) + n^\rho (|x|^{m+r} + |x|^{m+r+1} + \cdots)
\leq (10\varepsilon + n^\rho (1 - \delta)^{m+r})/\delta \leq k_0 \varepsilon .
\]

Hence if \( \varepsilon \) is small enough and \( n \) large enough, \( f \) must have at least as many zeros as \( B(x) \) within \((-1 + \delta, 1 - \delta)\). On the other hand, \( B^{(r)}(x) \) is a positive constant,
and for $x \in (-1 + \delta, 1 - \delta)$,
\[
|f^{(r)}(x) - B^{(r)}(x)| \leq 10 \epsilon \sum_{i=r}^{m+r-1} i^r |x|^{i-r} + n^\rho \sum_{i=m+r}^{\infty} i^r |x|^{i-r} \\
\leq 10 \epsilon \sum_{i=r}^{\infty} i^r (1 - \delta)^{(i-r)} + n^\rho \sum_{i=m+r}^{\infty} i^r (1 - \delta)^{(i-r)},
\]
which again can be made arbitrarily small by shrinking $\epsilon$. So, we can and shall assume $f^{(r)}(x) > 0$ in $(-1 + \delta, 1 - \delta)$. By Rolle’s Theorem, this bounds the number of real zeros of $f(x)$ in $(-1 + \delta, 1 - \delta)$ by $r$, so $f(x)$ has exactly $r$ zeros in $(-1 + \delta, 1 - \delta)$. Moreover, taking $\epsilon > 0$ such that $|B(x)| > \kappa_0 \epsilon$ for all $|x| \leq (1 - \delta)$, $x \notin U_i$, $i = 1, \ldots, k$, implies that the constant sign of $f(x)$ between each adjacent pair of intervals $U_i$ that are contained in $(-1 + \delta, 1 - \delta)$ is the same as the sign of $B(x)$ there. Hence $f(x)$ has exactly one zero in each of the $r$ intervals $U_i$ contained in $(-1, 1)$. Similar arguments (using C2 and C4) show that for some $\kappa_1 = \kappa_1(\delta)$ and all $|X| < (1 - \delta)$,
\[
|X^n f(X^{-1}) - C(X)| \leq \kappa_1 \epsilon,
\]
with the $s$-th derivative of the polynomial $X^n f(X^{-1})$ made positive throughout $|X| < (1 - \delta)$ by shrinking $\epsilon$. Recall that $C(X)$ has exactly one zero in each of the intervals inv($U_i$) for the $U_i$ contained in $(-\infty, -1) \cup (1, \infty)$. Thus, for small enough $\epsilon$, the same property holds for the $s$ zeros of $X^n f(X^{-1})$ within $|X| < (1 - \delta)$.

It thus remains to show that $x^r f(x) > 0$ for $(1 - \delta) \leq |x| \leq (1 - \delta)^{-1}$. Since $2r + m$ is an even integer, we have by condition C3 that for all $x \in \mathbb{R}$,
\[
x^r \left( \sum_{i=m+r}^{n-s-m} a_i x^i \right) = x^{2r+m} \left( \sum_{i=0}^{n-2m} a_{m+r+i} x^i \right) \geq 0.
\]
It is easy to check that
\[
h_m(x) := 8x^2 \sum_{j=0}^{(m-4)/2} x^{2j} - |x| \sum_{j=0}^{(m-2)/2} x^{2j} \geq 0,
\]
for all even $m \geq 4$ and $2/3 \leq |x| \leq 3/2$. Consequently, for $(1 - \delta) \leq |x| \leq (1 - \delta)^{-1}$ and $\delta < 1/3$, by condition C1,
\[
x^r \left( \sum_{i=r+1}^{m+r-1} a_i x^i \right) = x^{2r} \left( \sum_{i=1}^{m-1} a_{r+i} x^i \right) \geq \epsilon x^{2r} h_m(x) \geq 0,
\]
whereas for $r + (n-s) = 2r + n - k$ an even integer, by condition C2,
\[
x^r \left( \sum_{i=n-s-m+1}^{n-s-1} a_i x^i \right) = x^{r+(n-s)} \left( \sum_{i=1}^{m-1} a_{n-s-i} x^{-i} \right) \geq \epsilon x^{2r+n-k} h_m(x^{-1}) \geq 0.
\]
Next note that for sufficiently small $\epsilon > 0$, the polynomial $\sum_{i=0}^{r} a_i x^i$ has a positive leading coefficient and no zeros for $|x| \geq (1 - \delta)$, so $x^r \left( \sum_{i=1}^{r} a_i x^i \right) > 0$ for all $|x| \geq (1 - \delta)$. Similarly, $x^{-(n-s)} \sum_{i=n-s}^{n} a_i x^i$ is then a polynomial with positive constant coefficient and no zeros for $|x| \leq (1 - \delta)^{-1}$. With $r + (n-s)$ an even integer, it follows that $x^r \left( \sum_{i=n-s}^{n} a_i x^i \right) \geq 0$ for $|x| \leq (1 - \delta)^{-1}$. In view of (9.1)–(9.3), we find that $x^r f(x) > 0$ for $(1 - \delta) \leq |x| \leq (1 - \delta)^{-1}$. \qed
