QUANTIZATION OF QUASI-LIE BIALGEBRAS

BENJAMIN ENRIQUEZ AND GILLES HALBOUT

Let $k$ be a field of characteristic 0. Unless specified otherwise, “Lie algebra”, “vector space”, etc., mean “Lie algebra over $k$”, etc.

1. INTRODUCTION AND MAIN RESULTS

The main result of this paper is the construction of quantization functors of quasi-Lie bialgebras. We first recall the situation of this problem in the theory of quantum groups.

This theory started, on the mathematical side, with the discovery by Drinfeld and Jimbo of a noncocommutative deformation $U_q\mathfrak{g}$, in the category of Hopf algebras, of the enveloping algebra of a Kac-Moody Lie algebra. This discovery was soon related to important developments in knot theory and representation theory. At the same time, Drinfeld developed a program of formal deformation of enveloping algebras in the category of Hopf algebras (such a deformation is called a quantized universal enveloping, or QUE, algebra). Any QUE algebra leads to Lie algebraic data (more precisely, a Lie bialgebra), its “classical limit”, and Drinfeld asked whether a QUE algebra could be reconstructed from its classical limit; this question was solved by Etingof and Kazhdan, who constructed “quantization” functors from the category of Lie bialgebras to that of QUE algebras.

The introduction of $U_q\mathfrak{g}$ was motivated by mathematical physics, more precisely, the Wess-Zumino-Novikov-Witten model in conformal field theory. One of the mathematical incarnations of this model is the differential system obeyed by its correlation functions, the Knizhnik-Zamolodchikov (KZ) system. The relation between the KZ system and $U_q\mathfrak{g}$ was first made precise by Kohno, who expressed the monodromy representation of the KZ system using the representation theory of $U_q\mathfrak{g}$, when $\mathfrak{g}$ is finite dimensional. This theorem was then reproved by Drinfeld, who developed for this purpose the theory of quasi-Hopf algebras (QHAs). The main novel feature of this theory with respect to that of Hopf algebras is that the coassociativity axiom of the coproduct is weakened: namely the coassociativity identity $(\text{id} \otimes \Delta)(\Delta(x)) = (\Delta \otimes \text{id})(\Delta(x))$ for $x \in A$ is replaced by $(\text{id} \otimes \Delta)(\Delta(x)) = \Phi(\Delta \otimes \text{id})(\Delta(x))\Phi^{-1}$, where $\Phi \in A^{\otimes 3}$ is invertible and subject to a “pentagon” consistency condition. Similarly to Hopf algebras, QHAs lead to tensor categories via their categories of representations; finite-dimensional QHAs play an important role in the ongoing program of classification of finite tensor categories.

Drinfeld also developed a program for constructing a particular class of QHAs (the quasi-Hopf quantum universal enveloping, or QHQUE algebras) using formal
deformation theory. Namely, he showed that such a QHA gives rise to a Lie algebraic object called a quasi-Lie bialgebra (its classical limit). This gives rise to a functor \{QHQUE algebras\} \to \{quasi-Lie bialgebras\} (we recall this theory in Section 2). In [Dr4], Section 5, Drinfeld posed the problem of functorially constructing a QHQUE algebra corresponding to any given quasi-Lie bialgebra, i.e., of constructing a section \(Q\) of this functor, such that the structure maps of \(Q(a)\) can be expressed using the structure maps of a quasi-Lie bialgebra \(a\) using universal acyclic formulas; \(Q\) is then called a quantization functor for quasi-Lie bialgebras. This is the problem which we solve in the present paper.

As in the case of Lie bialgebras, quantization functors of quasi-Lie bialgebras are best defined in the framework of “props” (these are particular symmetric monoidal categories; see [McL] and Section 3.1). In Section 3.2, we introduce a graded prop \(QLBA\) of quasi-Lie bialgebras together with its completion \(\hat{QLBA}\). A quantization functor of quasi-Lie bialgebras is then the same as a QHQUE algebra in \(\hat{QLBA}\), satisfying suitable conditions (see Proposition 3.2); there are natural notions of equivalence and twist equivalence for these QHQUE algebras. In the same way, quantization functors for QUE algebras as in [EK2] may be viewed as certain QUE algebras in the prop \(LBA\) of Lie bialgebras. There is a natural prop morphism \(QLBA \to LBA\), which induces a map \(\{\text{quantization functors for quasi-Lie bialgebras}\} \to \{\text{quantization functors for Lie bialgebras}\}\). Our main result is then (Theorem 4.1):

**Theorem 1.1.** The map \(\{\text{quantization functors of quasi-Lie bialgebras}\}/(\text{equivalence, twist equivalence}) \to \{\text{quantization functors of Lie bialgebras}\}/(\text{equivalence})\) is a bijection.

Together with the results of [EK1, EK2], where is constructed a map \(\{\text{associators over } k\} \to \{\text{quantization functors of Lie bialgebras}\}\), and of [Dr3] on the existence of associators over \(k\), this result implies the existence of quantization functors for quasi-Lie bialgebras.

Let us explain the idea of the proof of Theorem 1.1. According to the Gerstenhaber-Schack deformation theory ([KS]), the obstruction to lifting a given deformation of a (quasi-)bialgebra \(A\) from order \(n\) to \(n+1\) belongs to a cohomology group \(H^4(A)(\tilde{H}^4(A)\) in the quasi case), and when this obstruction vanishes, such lifts modulo equivalence (and twists in the quasi case) form an affine space over \(H^3(A)(\tilde{H}^3(A)\) in the quasi case). When \(A = U(a)\) is an enveloping algebra, these cohomology groups have been computed by Shnider and Sternberg in terms of the Chevalley-Eilenberg cohomology and cocycle groups \(H^p(a, \Lambda^q(a))\) and \(Z^1(a, \Lambda^q(a))\) (see [ShSt]). We develop the categorical analogue of this theory in Sections 2.4, 2.6. In particular, we construct \(N\)-graded groups \(H^\bullet_{(Q)\text{LBA}} = \bigoplus_{n \geq 0} H^\bullet_{(Q)\text{LBA}}[n]\), such that \(H^\bullet_{(Q)\text{LBA}}[n+1]\) contains the obstruction to lifting a quantization functor of (quasi-)Lie bialgebras from order \(n\) to \(n+1\), and \(H^0_{(Q)\text{LBA}}[n+1]\) parametrizes classes of such lifts. This viewpoint is not used in the quantization of Lie bialgebras, since the groups \(H^\bullet_{\text{LBA}}\) are not known (in the same way, it is not known how to construct associators using deformation theory; see Remark 2, p. 854 in [Dr3]). However, this viewpoint can be used in our context. Namely, we construct maps \(H^\bullet_{\text{QLBA}} \to H^\bullet_{\text{LBA}}\), compatible with the map from Theorem 1.1, and prove:

**Theorem 1.2.** The map \(H^i_{\text{QLBA}} \to H^i_{\text{LBA}}\) is an isomorphism of \(N\)-graded vector spaces, for \(i \geq 0\).
Theorem 1.2 then follows immediately (see Section 3). Note that we use Theorem 1.1 only for taking tensor products with vector spaces $\mathbf{LBA}(\mathbf{Z})$ is reduced to the sum of its components, where the intermediate Schur functor be-
mediate Schur functor between a component of $\mathbf{LBA}(\mathbf{Z})$ is an irreducible Schur functor, and the space of cochains $Z$ is an irreducible Schur functor, and the space of cochains is reduced to the sum of its components, where the “intermediate Schur functor between $Z$ and $\Lambda^q$” is $Z$. (This notion is based on the structure theorem of $\mathbf{LBA}$; see Proposition 5.1.)

We say that the intermediate Schur functor between factors of $\mathbf{LBA}(\mathbf{Z})$ $\Lambda^p$ and $\Lambda^q$ is $\mathbf{id}$ (resp., has degree $>1$) and antisymmetric with respect to $S$. This subcomplex decomposes according to the intermediate Schur functors between the factors of $\mathbf{id} \otimes \mathbf{p}''$ and $\Lambda^q$, and these subcomplexes are obtained from the complexes $C^*_{\mathbf{LBA}} = (0 \to LBA(Z \otimes \mathbf{1} \otimes (\mathbf{Z}_i'' \otimes Z_i''), \Lambda^q) \to ... \to LBA(Z \otimes \Lambda^p \otimes (\mathbf{Z}_i'' \otimes Z_i''), \Lambda^q) \to ...)$ with the same differentials (the $Z_i''$ are irreducible Schur functors of degree $>1$) by taking tensor products with vector spaces $LCA(\mathbf{id}, Z_i'')$ and taking anti-invariants under $\mathbf{S}_{\mathbf{p}''}$. We therefore have to show the acyclicity of the complexes $C^*_{\mathbf{LBA}}$.

The proof of the acyclicity of this complex (Theorem 1.2, proof in Section 6) involves several reductions. We first show that in this complex, the spaces of cochains may be modified as follows: $\mathbf{LBA}_n(\mathbf{Z}, \mathbf{LCA}(\mathbf{Z}^2, \mathbf{LCA}^2)) = \mathbf{LBA}(\mathbf{Z} \otimes \mathbf{LCA}, \mathbf{LCA}^2)$, where $\mathbf{Z}$ is an irreducible Schur functor, and the space of cochains is reduced to the sum of its components, where the “intermediate Schur functor between $Z$ and $\Lambda^q$” is $Z$. (This notion is based on the structure theorem of $\mathbf{LBA}$; see Proposition 5.1.)

We say that the intermediate Schur functor between factors of $\mathbf{id} \otimes \mathbf{p}''$ and $\Lambda^q$ which are equal to $\mathbf{id}$. We identify the associated graded complex with a subcomplex of $0 \to \mathbf{LBA}(Z \otimes \mathbf{1} \otimes \mathbf{id} \otimes \mathbf{p}''', \Lambda^q) \to ... \to \mathbf{LBA}(Z \otimes \Lambda^p \otimes \mathbf{id} \otimes \mathbf{p}''', \Lambda^q) \to ...$, where the differential involves Lie brackets between the components of $\mathbf{id} \otimes \mathbf{p}'' \supset \Lambda^p$ and of these components with $Z$, formed by the sums of components, where the intermediate Schur functor between a component $\mathbf{id}$ of $\mathbf{id} \otimes \mathbf{p}'''$ (resp., of $\mathbf{id} \otimes \mathbf{p}''' \supset \Lambda^p$) and $\Lambda^q$ is $\mathbf{id}$ (resp., has degree $>1$) and antisymmetric with respect to $S_{\mathbf{p}''}$. This subcomplex decomposes according to the intermediate Schur functors between the factors of $\mathbf{id} \otimes \mathbf{p}'''$ and $\Lambda^q$, and these subcomplexes are obtained from the complexes $C^*_{\mathbf{Z}''} = (0 \to LBA(Z \otimes \mathbf{1} \otimes (\mathbf{Z}_i''' \otimes \mathbf{Z}_i''''), \Lambda^q) \to ... \to LBA(Z \otimes \Lambda^p \otimes (\mathbf{Z}_i''' \otimes \mathbf{Z}_i'''), \Lambda^q) \to ...)$ with the same differentials (the $Z_i'''$ are irreducible Schur functors of degree $>1$) by taking tensor products with vector spaces $LCA(\mathbf{id}, Z_i''')$ and taking anti-invariants under $S_{\mathbf{p}''}$.
For this, we show that $A^g$ may be replaced by $\text{id}^{\otimes q}$, $Z$ by $\text{id}^{\otimes z}$, and $\bigotimes_{i=1}^{z} Z_i$ by $\text{id}^{\otimes N}$ (where $Z, N$ are suitable integers), and we express the corresponding complex as a sum of tensor products of complexes. This reduces the problem to showing the acyclicity of a complex $0 \rightarrow LA(\text{id}^{\otimes z} \otimes 1 \otimes \text{id}^{\otimes N}, \text{id}) \rightarrow ... \rightarrow LA(\text{id}^{\otimes z} \otimes A^v \otimes \text{id}^{\otimes N}, \text{id}) \rightarrow ...$. The spaces of chains are now spaces of multilinear Lie polynomials. Using Dynkin’s correspondence between free Lie and free associative polynomials, we identify the complex with a complex $A_{\epsilon, N, 1}$, defined in terms of associative polynomials, which we decompose as a direct sum $\bigoplus_{\sigma} A_{\epsilon, N, 1}^\sigma$ of subcomplexes, indexed by permutations. We then identify each summand $A_{\epsilon, N, 1}^\sigma$ with a tensor product of “elementary” complexes. These complexes $E_{\epsilon, \epsilon'}$, $(\epsilon, \epsilon' \in \{0, 1\})$ are 1-dimensional in each degree, and are universal versions of the complexes computing the Lie algebra cohomology of a Lie algebra $g$ in $U(g)$, equipped with one of its trivial, adjoint, left or right $g$-module structures. We show that two of these complexes are acyclic, using the PBW filtration of free associative algebras (when $g$ is a finite-dimensional Lie algebra, the corresponding complexes have 1-dimensional cohomology, concentrated in degree $\dim g$). As $E_{\epsilon, 0, 1}$ necessarily enters the tensor product decomposition of each subcomplex $A_{\epsilon, N, 1}^\sigma$, the Künneth formula implies that each of the $A_{\epsilon, N, 1}^\sigma$ is acyclic, which implies that $A_{\epsilon, N, 1}^\sigma$ is acyclic.

In the final section of the paper, we apply Theorem 4.2 for proving that quantization functors of quasi-Lie bialgebras are compatible with twists (Proposition 7.1). This allows us to generalize our earlier results ([EH]) on compatibility of quantization functors of Lie bialgebras with twists; see Proposition 7.2 (in [EH], this result was established for Etingof-Kazhdan quantization functors, while Proposition 7.2 applies to any quantization functor of Lie bialgebras).

2. The problem of quantization of (quasi-)Lie bialgebras

In this section, we recall the basic results of the theory of quasi-Lie bialgebras and their quantum counterparts, QHQUE algebras. The material is essentially borrowed from [Dr2] [ShSi].

2.1. Quasi-Hopf algebras. A quasi-bialgebra over $k$ is a set $(A, \Delta, \epsilon, \Phi)$, where $A$ is an associative algebra with unit, $\Delta : A \rightarrow A^{\otimes 2}$ and $\epsilon : A \rightarrow k$ are morphisms of algebras with unit, and $\Phi \in (A^{\otimes 3})^\times$, such that \footnote{If $R$ is a ring with unit, we denote by $R^\times$ the group of its invertible elements.}

$$(\text{id} \otimes \Delta)(\Delta(a)) = \Phi(\Delta \otimes \text{id})(\Delta(a))\Phi^{-1}, \quad a \in A,$$

$$(\text{id}^{\otimes z} \otimes \Delta)(\Phi)(\Delta \otimes \text{id}^{\otimes z})(\Phi) = (1 \otimes \Phi)(\text{id} \otimes \Delta \otimes \text{id})(\Phi)(\Phi \otimes 1),$$

$$(\epsilon \otimes \text{id})(\Delta(a)) = a = (\text{id} \otimes \epsilon)(\Delta(a)), \quad a \in A,$$

$$(\text{id} \otimes \epsilon \otimes \text{id})(\Phi) = 1.$$
A quasi-Hopf algebra is a quasi-bialgebra equipped with supplementary data satisfying axioms, which in the bialgebra case reduce to the existence and invertibility of an antipode (see [Dr2]).

We now introduce generalizations of the above notions in symmetric tensor categories. Let \(\mathcal{C}\) be a symmetric tensor category\(^2\) with unit object \(1\).

An algebra with unit in \(\mathcal{C}\) is a triple \((X, m, \eta)\), where \(X \in \text{Ob}(\mathcal{C})\), \(m \in \mathcal{C}(X \otimes X, X)\), \(\eta \in \mathcal{C}(1, X)\), such that \(m \circ (m \otimes \text{id}_X) = m \circ (\text{id}_X \otimes m)\) and \(m \circ (\eta \otimes \text{id}_X) = \text{id}_X = m \circ (\text{id}_X \otimes \eta)\). If \((X_i, m_i, \eta_i)\) are algebras with unit in \(\mathcal{C}\) \((i = 1, 2)\), then a morphism from \(X_1\) to \(X_2\) is an \(f \in \mathcal{C}(X_1, X_2)\), such that \(f \circ m_1 = m_2 \circ f \otimes 2\), \(\eta_2 = f \circ \eta_1\).

If \((X_i, m_i, \eta_i), i = 1, 2\), are algebras with unit in \(\mathcal{C}\), then so is \((X_1 \otimes X_2, m, \eta_1 \otimes \eta_2)\), where \(m = (m_1 \otimes m_2) \circ (\text{id}_X \otimes \beta \otimes \text{id}_{X_2})\), and \(\beta : X_2 \otimes X_1 \to X_1 \otimes X_2\) is the commutativity constraint in \(\mathcal{C}\). In particular, if \(X\) is an algebra with unit in \(\mathcal{C}\), then so is \(X^\otimes n\) for \(n \geq 0\) \((X^\otimes 0 = 1)\).

If \((X, m, \eta)\) is an algebra with unit in \(\mathcal{C}\), then \(\mathcal{C}(1, X)\) is equipped with the structure of a \(k\)-algebra with unit, with product \(f \ast g := m \circ (f \otimes g)\) and unit \(\eta\). Moreover, for any \(Y \in \text{Ob}(\mathcal{C})\), the space \(\mathcal{C}(Y, X)\) is equipped with a \(\mathcal{C}(1, X)\)-bimodule structure, where \(f \ast x \ast g := m^{(2)} \circ (f \otimes x \otimes g)\), and \(m^{(2)} = m \circ (m \otimes \text{id}_X)\).

A quasi-bialgebra in \(\mathcal{C}\) is then defined as a set \((X, \Delta, \epsilon, \Phi)\), where \((X, m, \eta)\) is an algebra in \(\mathcal{C}\), \(\Delta \in \mathcal{C}(X, X^\otimes 2)\) and \(\epsilon \in \mathcal{C}(X, 1)\) are morphisms of algebras with unit in \(\mathcal{C}\), and \(\Phi \in \mathcal{C}(1, X^\otimes 3)\)\(^\times\), such that

\[
\begin{align*}
(id_X \otimes \Delta) \circ \Delta &= \Phi \ast ((\Delta \otimes \text{id}_X) \circ \Delta) \ast \Phi^{-1}, \\
((id_X^\otimes 2 \otimes \Delta) \circ \Phi) \ast ((\Delta \otimes id_X^\otimes 2) \circ \Phi) &= (\eta \otimes \Phi) \ast ((id_X \otimes \Delta \otimes \text{id}_X) \circ \Phi) \ast (\Phi \otimes \eta), \\
(\epsilon \otimes id_X) \circ \Delta &= \text{id}_X = (id_X \otimes \epsilon) \circ \Delta, \\
(id_X \otimes \epsilon \otimes id_X) \circ \Phi &= \eta^\otimes 2.
\end{align*}
\]

When \(\Phi = \eta^\otimes 3\), this definition reduces to that of a bialgebra in \(\mathcal{C}\). As above, the group \(\mathcal{C}(1, X^\otimes 2)\)\(^\times\) acts on the set of quasi-bialgebra structures over \(X\) by \(\Delta = F \ast \Delta \ast F^{-1}\),

\[\tilde{\Phi} := (\eta \otimes F) \ast ((id_X \otimes \Delta) \circ F) \ast \Phi \ast ((\Delta \otimes id_X) \circ F)^{-1} \ast (F \otimes \eta)^{-1}.\]

One can similarly introduce the notion of a (quasi-)Hopf algebra in \(\mathcal{C}\). Similarly to associative algebras with unit, (quasi-)bialgebras, (quasi-)Hopf algebras in \(\mathcal{C}\) form a category.

When \(\mathcal{C} = \text{Vect}\) (the category of \(k\)-vector spaces), one recovers the notion of an associative algebra with unit, of a (quasi-)bialgebra, and of a (quasi-)Hopf algebra over \(k\).

\(^2\)We denote by \(\mathcal{C}(X, Y)\) the set of morphisms between two objects of \(\mathcal{C}\), and by \(\text{End}_\mathcal{C}(X)\) and \(\text{Aut}_\mathcal{C}(X)\) the sets of endomorphisms and automorphisms of an object of \(\mathcal{C}\).
2.2. Quasi-Lie bialgebras. A quasi-Lie bialgebra over \( k \) is a set \((a, \delta, \varphi)\), where \( a \) is a Lie algebra over \( k \), and \( \delta : a \to \Lambda^2(a) \) and \( \varphi \in \Lambda^3(a) \) are such that\(^3\)
\[
\delta([x, y]) = [x \otimes 1 + 1 \otimes x, \delta(y)] + [\delta(x), y \otimes 1 + 1 \otimes y], \quad x, y \in a,
\]
\[
\frac{1}{2} \text{Alt}_3(\delta \otimes \text{id})(\delta(x)) = [x \otimes 1 + 1 \otimes x \otimes 1 + 1 \otimes x, \varphi], \quad x \in a,
\]
\[
\text{Alt}_4(\delta \otimes \text{id} \otimes \text{id})(\varphi) = 0.
\]
Here \( \text{Alt}_k : a^\otimes k \to a^\otimes k \) is the operator \( \sum_{\sigma \in S_k} \text{sgn}(\sigma) \sigma \).

When \( \varphi = 0 \), this definition reduces to that of a Lie bialgebra.

If \( f \in \Lambda^2(a) \), we define the twist of \((a, \delta, \varphi)\) by \( f \) as \((a, \tilde{\delta}, \tilde{\varphi})\), where
\[
\tilde{\delta}(x) = \delta(x) + [x \otimes 1 + 1 \otimes x, f], \quad \tilde{\varphi} = \varphi + \frac{1}{2} \text{Alt}_3((\delta \otimes \text{id})(f) + [f^{12}, f^{23}]).
\]
This defines an action of the additive group \( \Lambda^2(a) \) on the set of quasi-Lie bialgebra structures over the Lie algebra \( a \).

If now \( C \) is a symmetric tensor category, then a quasi-Lie bialgebra in \( C \) is a set \((x, \mu, \delta, \varphi)\), where \( x \in \text{Ob}(C) \), \( \mu \in C(x^{\otimes 2}, x), \delta \in C(x, x^{\otimes 2}), \varphi \in C(1, x^{\otimes 3}) \), such that:
\[
\mu \circ \beta = -\mu, \quad \beta \circ \delta = -\delta, \quad \beta_{\sigma} \circ \varphi = \epsilon(\sigma)\varphi
\]
for \( \sigma \in S_3 \) (here \( \beta \in \text{Aut}_C(x^{\otimes 2}) \) and the morphisms \( S_k \to \text{Aut}_C(x^{\otimes k}) \), \( \sigma \mapsto \beta_{\sigma} \) are induced by the commutativity constraint), and
\[
\mu \circ (\mu \otimes \text{id}_x) \circ \text{Alt}_3 = 0, \quad \delta \circ \mu = \text{Alt}_2(\mu \otimes \text{id}_x) \circ (\text{id}_x \otimes \delta) \circ \text{Alt}_2,
\]
\[
\text{Alt}_3(\delta \otimes \text{id}_x) \circ \delta = \text{Alt}_3(\mu \otimes \text{id}_x^{\otimes 2}) \circ (\text{id}_x \otimes \varphi), \quad \text{Alt}_4(\delta \otimes \text{id}_x^{\otimes 3}) \circ \varphi = 0,
\]
where, as above, \( \text{Alt}_k = \sum_{\sigma \in S_k} \text{sgn}(\sigma) \beta_{\sigma} \in \text{End}_C(x^{\otimes k}) \).

When \( \varphi = 0 \) (resp., \( \varphi = 0 \) and \( \delta = 0 \)), this definition reduces to that of a Lie bialgebra (resp., Lie algebra) in \( C \). When \( C = \text{Vect} \), we recover the notions of (quasi-)Lie (bi)algebra over \( k \).

2.3. QHQUE algebras. Let \( h \) be a formal variable. Topologically free \( k[[h]] \)-modules are modules of the form \( V[[h]] \), where \( V \) is a vector space. We call \( \text{Vect}_h \) the tensor category of topologically free \( k[[h]] \)-modules; then reduction mod \( h \) is a tensor functor \( \text{Vect}_h \to \text{Vect} \).

A QUE (quasi-)bialgebra is a (quasi-)bialgebra \((A, \Delta, \epsilon, \Phi)\) in \( \text{Vect}_h \), whose reduction mod \( h \) is a universal enveloping algebra and such that \( \text{Alt} \Phi \in h^2 A^\otimes 3 \). One similarly defines (quasi-)Hopf QUE algebras. It follows from [Dr2], Theorem 1.6, that a QUE (quasi-)bialgebra is equipped with a unique (quasi-)Hopf structure.

We define \( \{(Q)\text{HQUE algebras over } k\} \) as the full subcategory of \( \{(Q)\text{-Hopf algebras in } \text{Vect}_h\} \) whose objects are the \( (Q)\text{HQUE algebras} \).

We now define the classical limit functor \( \{(Q)\text{HQUE algebras over } k\} \to \{(\text{quasi-})\text{Lie bialgebras over } k\} \). If \( A \) is a \( (Q)\text{HQUE algebra}, \) then its reduction mod \( h \) has the form \( U(a) \), where \( a \) is a Lie algebra. If \( a \in a \) and \( a \in A \) is any lift of \( a \), then \( (h^{-1} \text{Alt} \Delta(\tilde{a}) \mod h) \in \Lambda^2(U(a)) \) in fact belongs to \( \Lambda^2(a) \), and depends only on \( a \). This defines a map \( \delta : a \to \Lambda^2(a) \). Letting \( \varphi := (h^{-2} \text{Alt} \Phi \mod h) \in \Lambda^3(U(a)) \), one proves that in fact \( \varphi \in \Lambda^3(a) \) and that \((a, \delta, \varphi)\) is a quasi-Lie bialgebra. The assignment \( A \mapsto (a, \delta, \varphi) \) is the classical limit functor

\(^3\)We view \( \Lambda^k(a) \) as a subspace of \( a^\otimes k \).
{QHQUE algebras} → {quasi-Lie bialgebras}. It restricts to a functor \{Hopf QUE algebras\} → \{Lie bialgebras\}.

If \((A, m, \Delta, \Phi)\) is obtained from \((A, m, \Delta, \Phi)\) by twisting by \(F \in 1 + hA^{\otimes 2}\), and if \(\Phi, \tilde{\Phi} \in 1 + h^2A^{\otimes 3}\), then \(f := -(h\text{Alt}(F) \mod h) \in \Lambda^2(a)\) and the classical limit \((a, \delta, \phi)\) of \((A, ..., \Phi)\) is obtained from \((a, \delta, \phi)\) by twisting by \(f\).

2.4. Categorical versions of (QH)QUE algebras. Let \((x, \mu)\) be a Lie algebra in a symmetric tensor category \(C_0\). Assume that:

1. for any projector \(p \in Q\text{S}_n\), its image \(p_{x} \in \text{End}_{C_0}(x^{\otimes n})\) admits a kernel and a cokernel; this enables us to define the symmetric and exterior powers \(S^n(x)\) and \(\Lambda^n(x)\) as objects of \(C_0\);

2. the class of objects of \(C_0\) contains the infinite direct sum \(S(x) = \bigoplus_{n \geq 0} S^n(x)\).

Then there exists a unique bialgebra structure on \(S(x)\) in \(C_0\) such that:

(a) the coproduct \(\Delta_0: S(x) \to S(x)^{\otimes 2}\) is the sum of the morphisms \((x^{a+b})_{\Delta}^{(a+b)}(x)\)

(b) the product \(m_{x, \mu}: S(x)^{\otimes 2} \to S(x)\) is such that the composition \(S(x)^{\otimes 2} \otimes S(x) \to S(x)\) coincides with the sum over \(a, b \geq 0\) of the morphisms \(S^n(x) \otimes S^b(x) \to x\), obtained by replacing the Lie bracket by \(\mu\) in the Lie series \(c_{a, b}(x_1, ..., x_n)|_{y_1, ..., y_b}\) defined by the conditions: (i) it is multilinear in \(x_1, ..., y_b\), and symmetric in each group of variables \((x_a)_{a=1}^{n}\) and \((y_b)_{b=1}^{m}\); (ii) \(c_{a, b}(x, ..., x, y, ..., y) = ab!c_{a, b}(x, y)\), where \(c(x, y) = \log(e^x e^y) = \sum c_{a, b}(x, y)\) is the decomposition of the Campbell-Hausdorff series according to the degrees in \(x, y\).

We will call the bialgebra \((S(x), m_{x, \mu}, \Delta_0)\) the universal enveloping (UE) algebra of \((x, \mu)\) and denote it by \(U(x)\).

Now let \(\mathcal{C}\) be an \(N\)-graded symmetric tensor category with a Lie algebra object \(x\) satisfying conditions (1) and (2) (with \(C_0\) replaced by \(\mathcal{C}\)). The \(N\)-grading condition means that \(\mathcal{C}(X, Y) = \bigoplus_{d \geq 0} C(X, Y)[d]\), the composition and tensor product are compatible with the grading, and the commutativity constraints have degree 0. Then \(\mathcal{C}\) gives rise to a completed category \(\hat{\mathcal{C}}(X, Y) = \prod_{n \geq 0} C(X, Y)[n]\), categories \(\mathcal{C}_{\leq d}\) with \(\mathcal{C}_{\leq d}(X, Y) = \bigoplus_{i=0}^{d} C(X, Y)[i]\), and functors \(\ldots \to \mathcal{C}_{\leq d} \to \ldots \to \mathcal{C}_{\leq 0}\).

A (QH)QUE algebra in \(\hat{\mathcal{C}}\) quantizing \(U(x)\) is a (quasi-)bialgebra structure \((m, \Delta, \epsilon, \eta)\) (resp., \((m, ..., \mu)\)) on \(S(x)\) in \(\hat{\mathcal{C}}\), whose image in \(C_{\leq 0}\) is \(U(x)\). In the “quasi” case, one adds the condition that \(\Phi = \eta^{\otimes 3}\) in \(C_{\leq 0}\), and \(\text{Alt}_3 \Phi = 0\) in \(C_{\leq 1}\). Two (QH)QUE algebras \((m, \Delta, \epsilon, \eta)\) and \((m', \Delta', \epsilon', \eta')\) are called equivalent if they are related by some \(i \in \text{Ker}(\text{Aut}_{\mathcal{C}}(S(x))) \to \text{Aut}_{\mathcal{C}_0}(S(x)))\), i.e., \(m' = i \circ m \circ (i^{-1})^{\otimes 2}\), etc. One also defines twists of QHQUE algebras as above.

One recovers the usual notion of a (QH)QUE algebra as follows. First note that \(\text{Vect}_h\) is equivalent to the category \(\text{Vect}[[h]]\), where objects are \(k\)-vector spaces and \(\text{Vect}[[h]](X, Y) = \text{Vect}(X, Y)[[h]]\). Let \(\tilde{\mathcal{C}} := \text{Vect}[[h]]\), the category where objects are vector spaces and morphisms are given by \(\text{Vect}[[h]](X, Y) = \text{Vect}(X, Y)[[h]]\); the grading is given by powers of \(h\). Then \(\tilde{\mathcal{C}} = \text{Vect}[[h]]\). A (QH)QUE algebra quantizing \((a, \mu)\) is then the same as a (QH)QUE algebra in \(\text{Vect}[[h]]\) quantizing \(U(a)\).

2.5. Deformation complexes. In [GS], Gerstenhaber and Schack constructed a deformation theory for bialgebras. It can be summarized as follows. For \((A, m, \Delta)\) a bialgebra, there is a bicomplex \(C(A) = \bigoplus_{p, q \geq 0} C^{p, q}\), with \(C^{p, q} := \text{Vect}(A^{\otimes p}, A^{\otimes q})\)
and differentials $d^{p,q} : C^{p,q} \to C^{p+1,q}$, $d^e_{p,q} : C^{p,q} \to C^{p,q+1}$ given by

$$(d^{p,q}\sigma)(a_1 \otimes \ldots \otimes a_{p+1}) := \Delta^{(q-1)}(a_1) \ast \sigma(a_2 \otimes \ldots \otimes a_{p+1})$$

$$+ \sum_{i=1}^{p} (-1)^i \sigma(a_1 \otimes \ldots \otimes a_i a_{i+1} \otimes \ldots \otimes a_{p+1}) + (-1)^{p+1} \sigma(a_1 \otimes \ldots \otimes a_p) \ast \Delta^{(q-1)}(a_{p+1}),$$

where $\ast$ is the product on $A^{\otimes q}$, $\Delta^{(q-1)} : A \to A^{\otimes q}$ is the $(q-1)$th iterate of $\Delta$, and

$$(d^e_{p,q}\sigma)(a_1 \otimes \ldots \otimes a_p) := (a_1(1) \ast \ldots \ast a_{p(1)}) \otimes \sigma(a_{p(2)} \otimes \ldots \otimes a_{p(2)})$$

$$+ \sum_{j=1}^{q} (-1)^j \Delta_j(\sigma(a_1 \otimes \ldots \otimes a_p)) + (-1)^{q+1} \sigma(a_1(1) \otimes \ldots \otimes a_{p(1)}) \otimes (a_{1(2)} \ast \ldots \ast a_{p(2)}),$$

where $\ast$ is now the product in $A$, $\Delta_j = \text{id}^{\otimes j-1} \otimes \Delta \otimes \text{id}^{\otimes q-j-1}$, and we use Sweedler’s notation $\Delta(a) = a_{(1)} \otimes a_{(2)}$. The total cohomology is denoted by $H^\bullet(A)$. Obstruction to prolongation of a general deformation of $A$ at a given order belongs to $H^4(A)$, and if this obstruction vanishes, the space of possible prolongations, modulo equivalences, is an affine space over $H^3(A)$ (see [ShSt], Props. 10.9.1 and 10.9.2). In [ShSt], Shnider and Sternberg construct a theory for the deformation of a bialgebra $A$ in the category of quasi-bialgebras. The relevant bicomplex is $\tilde{C}(A) = \bigoplus_{p,q \geq 0} C^{p,q}(A)$ with the same differentials as above (only one row has been added to the bicomplex). Obstructions and parametrizations of prolongations of formal deformations of $A$ in the category of quasi-bialgebras (modulo twists and equivalences) then belong to the total cohomologies $\tilde{H}^3(A)$ and $\tilde{H}^4(A)$.

When $a$ is a Lie algebra and $A = U(a)$, these cohomology groups are given by

- $H^n(A) = \bigoplus_{p+q=n; p,q \geq 0} H^{p,q}$, where $H^{p,q} = H^q(a, \Lambda^p(a))$ if $q > 1$, and $H^{p,1} = Z^1(a, \Lambda^p(a))$;
- $\tilde{H}^n(A) = \bigoplus_{p+q=n; p,q \geq 0} \tilde{H}^{p,q}$, where $\tilde{H}^{p,q} = H^q(a, \Lambda^p(a))$; here $a$ acts on $\Lambda^p(a)$ via the adjoint action (see [ShSt], Props. 10.9.1 and 10.9.2).  

2.6. Categorical deformation complexes. Let $C$ be an $\mathbb{N}$-graded symmetric tensor category (so $\tilde{C}(X,Y) = \prod_{d \geq 0} C(X,Y)[d]$). Let $(X, m, \Delta)$ be a bialgebra in $C_{\leq 0}$; we have a functor $C_{\leq 0} \to C$, so it is a bialgebra in $C$. We construct a bicomplex $\tilde{C}(X) = \bigoplus_{p,q \geq 0} C^{p,q}$, with $C^{p,q} := \tilde{C}(X^{\otimes p}, X^{\otimes q})$ and differentials

$$d^{p,q}(\sigma) := m^{\otimes q} \circ \beta_{q,2} \circ (\Delta^{(q-1)} \otimes \sigma) + \sum_{i=1}^{p} (-1)^i \sigma \circ (\text{id}^{\otimes i-1} \otimes m \otimes \text{id}^{\otimes p-1-i})$$

$$+ (-1)^{p+1} m^{\otimes q} \circ \beta_{q,2} \circ (\sigma \otimes \Delta^{(q-1)}),$$

$$d^e_{p,q}(\sigma) := (m^{(q-1)} \otimes \sigma) \circ \beta_{2,p} \circ \Delta^{\otimes p} + \sum_{j=1}^{q} (-1)^j (\text{id}^{\otimes j-1} \otimes \Delta \otimes \text{id}^{\otimes q-j-1}) \circ \sigma$$

$$+ (-1)^{q+1} (\sigma \circ m^{(p-1)}) \circ \beta_{2,p} \circ \Delta^{\otimes p},$$

where $\beta_{n,m} : (X^{\otimes n})^{\otimes m} \to (X^{\otimes m})^{\otimes n}$ is the morphism induced by the natural bijection $\{1, \ldots, n\} \times \{1, \ldots, m\} \to \{1, \ldots, m\} \times \{1, \ldots, n\}$.

These differentials have degree 0 for the $\mathbb{N}$-grading of $C$, so the resulting total cohomology $H^\bullet(X)$ is $\mathbb{N}$-graded. A lifting of $(m, \Delta)$ to a bialgebra structure on $X$ in $C_{\leq n}$ being given, the obstruction to lifting it further to $C_{\leq n+1}$ is a class in $H^4(X)[n+1]$, and when this class vanishes, the set of possible lifts modulo
equivalence (i.e., the natural action of Ker(Aut_C(X) → Aut_{C,<n>}(X))) is an affine space over H^3(C)[n + 1].

The bicomplex controlling the deformations of (X, m, ∆) as a quasi-bialgebra in \( \hat{C} \) is \( \hat{C}(X) := \bigoplus_{p,q \geq 0} C^{p,q} \) with the same differentials. Its cohomology \( \hat{H}^*(X) \) is again \( \mathbb{N} \)-graded. A lifting of \((m, ∆, η^{(3)}) \) in \( C_{\leq n} \) being given, the obstruction to lifting it to \( C_{\leq n+1} \) is a class in \( \hat{H}^4(C)[n + 1] \), and if this class vanishes, the set of possible lifts modulo equivalences and twists is an affine space over \( \hat{H}^3(C)[n + 1] \).

If now \((C_{\leq 0}, x, μ) = \) as in Section 2.4 and \((X, m, ∆) = U(x)\), the cohomology groups \( H^*(X) \) may be computed as follows. Set \( c(X) := \bigoplus_{p,q \geq 0} c^{p,q}(x) \), where \( c^{p,q}(x) := \mathcal{C}(\Lambda^p(x), \Lambda^q(x)) \) (we view \( c^{p,q}(x) \) as a subspace of \( \mathcal{C}(x^{S \rho}, x^{S \eta}) \)).

According to [KS, LR], \( c(X) \) is equipped with a structure of a \( \mathbb{Z}^2 \)-graded Lie superalgebra, where \( c^{p,q}(x) \) has bidegree \( (p - 1, q - 1) \). The bracket is defined by \([a, a'] := a \circ a' - (-1)^{(p+q)(p'+q')} a' \circ a \) for \( a \in c^{p,q}(x) \), \( a' \in c^{p',q'}(x) \), where \( a \circ a' := (-1)^{(p+q)(p'+q'-1)} Alt_{q+q'-1}(characteristics) \circ (id_X^{S \rho-1} \circ a') \circ Alt_{p+q'-1}(characteristics) \) if \( p, q' \geq 1 \) and 0 otherwise. As \( μ \in c^{2,1}(x) \) defines a Lie structure, we have \([μ, μ] = 0\). It follows that for any \( q \geq 0 \), \( c^{p,q}(x) := (\mathcal{C}(\Lambda^p, \Lambda^q), [μ, -]) \) is a complex; its cocycle and cohomology groups are denoted by \( Z^*(U(x)) \) and \( H^*(U(x)) \).

The cohomology groups \( H^*(U(x)) \) and \( \hat{H}^*(U(x)) \) are then computed by the same formulas as in the case of \( A = U(a) \), replacing \( a \) by \( x \); the gradings of these groups are induced by the grading of \( C \).

3. Quantization functors

According to [Dr4], a quantization functor for (quasi-)Lie bialgebras is a section of the classical limit functor \{\( (Q) \)HQ algebra\} → \{(quasi-)Lie bialgebras\}, such that the structure maps of \( Q(a) \) may be expressed by universal acyclic formulas involving the structure maps of the (quasi-)Lie bialgebra \( a \). As was observed in [EK2], the definition of quantization functors is best expressed in the setup of props, which we first recall.

3.1. The theory of props. Recall the definitions of the Schur categories \( Sch \) and \( Sch (\mathbb{E}H) \). These are braided symmetric tensor categories, defined as follows. The objects of \( Sch \) are Schur functors, i.e., finitely supported families \( X = (X_ρ)_ρ \) of finite-dimensional vector spaces, where \( ρ \in \bigsqcup_{n \geq 0} \hat{S}_n \) (\( ρ \) is therefore a pair \((n, π_ρ)\), where \( n \geq 0 \) and \( π_ρ \) is an irreducible representation of \( \hat{S}_n \); \( n \) is called the degree of \( ρ \); by convention, \( \hat{S}_0 \) is the trivial group). The set of morphisms from \( X \) to \( Y \) is \( Sch(X, Y) := \bigoplus_ρ \text{Vect}(X_ρ, Y_ρ) \). The direct sum of objects is \( X \oplus Y = (X_ρ \oplus Y_ρ)_ρ \).

Their tensor product is \( X \otimes Y = (\bigoplus_ρ ρ^p \otimes X_ρ \otimes Y_ρ)_ρ \), where for \( ρ', ρ'' \in \hat{S}_n \), \( ρ' \in \hat{S}_n \), \( ρ'' \in \hat{S}_n \), we set \( M^{p,q}_{ρ,ρ''} = [π_ρ : \text{Ind}\hat{S}_n^{ρ×ρ''}(π_ρ \otimes π_q)] \) if \( n = n' + n'' \) and 0 otherwise. \( Sch \) is defined similarly, dropping the condition that \( X \) is finitely supported.

An object \( X \) of \( Sch \) or \( Sch \) is called homogeneous of degree \( n \) iff \( X_ρ = 0 \) if the degree of \( ρ \) is \( \neq n \). If \( X \) is homogeneous, we denote by \(|X|\) its degree.

We have a bijection \( \text{Irr}(Sch) \simeq \bigsqcup_{n \geq 0} \hat{S}_n \), where \( \text{Irr}(Sch) \) is the set of equivalence classes of irreducible objects in \( Sch \). The unit object of \( Sch \) is \( 1 \), which corresponds to the element of \( \hat{S}_0 \). We also define \( id, S^p, Λ^p \) as the objects corresponding to: the element of \( \hat{S}_1 \), the trivial and the signature character of \( \hat{S}_p \). We set \( T_p := id^{⊗p} \) and \( S := \bigoplus_{p \geq 0} S^p \in \text{Ob}(Sch) \).
A prop (resp., an Sch-prop) is then an additive symmetric monoidal category \( C \), equipped with a tensor functor \( \text{Sch} \rightarrow C \) (resp., \( \text{Sch} \rightarrow C \)), which is the identity on objects.

A prop morphism \( C \rightarrow D \) is a tensor functor, such that the functors \( \text{Sch} \rightarrow C \rightarrow D \) and \( \text{Sch} \rightarrow D \) coincide. An ideal \( I \) of the prop \( C \) is an assignment \( (X,Y) \mapsto I(X,Y) \subset C(X,Y) \), such that \( (X,Y) \mapsto C(X,Y)/I(X,Y) =: C/I(X,Y) \) is a monoidal category; \( C/I \) is then called the quotient prop. If \( f_\alpha \in C(X_\alpha,Y_\alpha) \) are morphisms in \( C \), then the ideal \( \langle f_\alpha \rangle \) is the smallest ideal \( I \) in \( C \) such that \( f_\alpha \in I(X_\alpha,Y_\alpha) \).

Props may be presented by generators and relations. If \( \mathcal{V} = (V_{n,m})_{n,m \geq 0} \) is a collection of vector spaces, there is a unique prop \( \text{Free}(\mathcal{V}) \), such that for any prop \( C \), we have a bijection \( \prod_n \text{Vect}(V_{n,m}, \mathcal{C}(T_n,T_m)) \cong \text{Prop}(\text{Free}(\mathcal{V}),C) \) (where Prop denotes the set of prop morphisms). If \( \mathcal{R} = (R_{n,m})_{n,m \geq 0} \) is a collection of subspaces of the \( \text{Free}(\mathcal{V})(T_n,T_m) \), then the ideal generated by \( \mathcal{V} \) with relations \( \mathcal{R} \) is the quotient prop \( \text{Free}(\mathcal{V})/\langle \mathcal{R} \rangle \).

We say that \( C \) is a topological prop if for any \( X,Y \in \text{Ob}(\text{Sch}) \) we have a filtration \( C(X,Y) = C^{\geq 0}(X,Y) \supset C^{\geq 1}(X,Y) \supset \ldots \), complete and separated, and compatible with the prop operations (i.e., \( C^{\geq b}(Y,Z) \circ C^{\geq a}(X,Y) \subset C^{\geq a+b}(X,Z) \) and \( C^{\geq a}(X,Y) \otimes C^{\geq a'}(X',Y') \subset C^{\geq a+a'}(X \otimes X', Y \otimes Y') \)).

Then \( \text{id} \) is a Lie bialgebra in \( LBA \), and it is an initial object in the category of props equipped with a Lie bialgebra structure on \( \text{id} \).

A prop \( LBA \) of Lie algebras is defined by generators \( \mu \in LBA(\text{id}^{\otimes 2}, \text{id}) \), \( \delta \in LBA(\text{id}, \text{id}^{\otimes 2}) \) and relations \( \mu \circ \beta = -\mu \), \( \beta \circ \delta = -\delta \), \( \mu \circ (\mu \otimes \text{id}_\delta) \circ \text{Alt}_3 = 0 \), \( \text{Alt}_3 \circ (\delta \otimes \text{id}_\mu) \circ \delta = 0 \), \( \delta \circ \mu = \text{Alt}_2 \circ (\mu \otimes \text{id}_\delta) \circ (\text{id}_\delta \otimes \delta) \circ \text{Alt}_2 \).

Then \( \text{id} \) is a Lie bialgebra in \( LBA \), and it is an initial object in the category of props equipped with a Lie bialgebra structure on \( \text{id} \).

A prop \( LBA \) is graded by \( \mathbb{N}^2 \), with \( \mu, \delta \) of degrees \( (1,0), (0,1) \); we denote by \( \text{deg}_\mu, \text{deg}_\delta \) this grading. LBA is then \( \mathbb{N} \)-graded by the total degree \( \text{deg}_\mu + \text{deg}_\delta \). If \( x \in LBA(X,Y) \) and \( X, Y, x \) are homogeneous, then \( \text{deg}_\mu(x) - \text{deg}_\delta(x) = |X| - |Y| \), so \( LBA(X,Y) = LBA^{\geq |X|-|Y|}(X,Y) \). So the total degree completion of \( LBA \) is a topological prop. We denote by \( LBA \) the corresponding Sch-prop.

The prop \( QLBA \) of quasi-Lie bialgebras is defined by generators \( \mu \in QLBA(\text{id}^{\otimes 2}, \text{id}) \), \( \delta \in QLBA(\text{id}, \text{id}^{\otimes 2}) \), \( \varphi \in QLBA(\text{id}, \text{id}^{\otimes 2}) \) and relations \( \mu \circ \beta = -\mu \), \( \beta \circ \delta = -\delta \), \( \beta_\sigma \circ \varphi = \text{sgn}(\sigma) \varphi \), \( \sigma \in S_3 \),

\[
\mu \circ (\mu \otimes \text{id}_\delta) \circ \text{Alt}_3 = 0, \quad \delta \circ \mu = \text{Alt}_2 \circ (\mu \otimes \text{id}_\delta) \circ (\text{id}_\delta \otimes \delta) \circ \text{Alt}_2, \quad \text{Alt}_3 \circ (\delta \otimes \text{id}_\mu) \circ \delta = \text{Alt}_3 \circ (\mu \otimes \text{id}_\delta) \circ (\text{id}_\delta \otimes \varphi), \quad \text{Alt}_4 \circ (\delta \otimes \text{id}_\mu) \circ \varphi = 0.
\]

This prop is graded by \( \{(u,v) \in \mathbb{Z}^2 \mid v \geq 0, 2u + v \geq 0\} \), with \( \mu, \delta, \varphi \) of degrees \( (1,0), (0,1), (-1,2) \); we denote this grading by \( \text{deg}_\mu, \text{deg}_\delta, \text{deg}_\varphi \). QLBA is then \( \mathbb{N} \)-graded by the total degree \( \text{deg}_\mu + \text{deg}_\delta \); the generators then have degree 1. If \( x \in QLBA(X,Y) \) and \( x, X, Y \) are homogeneous, then \( \text{deg}_\mu(x) - \text{deg}_\delta(x) = |X| - |Y| \), so \( QLBA(X,Y) = QLBA^{\geq |X|-|Y|}(X,Y) \), which implies that the total degree
completion of QLBA is a topological prop. We denote by QLBA the corresponding \textbf{Sch}-prop. In the prop QLBA, the object \textit{id} is equipped with a quasi-Lie bialgebra structure, and QLBA is an initial object in the category of props equipped with a quasi-Lie bialgebra structure on \textit{id}.

We have a natural isomorphism LBA \simeq QLBA/\langle \varphi \rangle, and we denote by \( x \mapsto (x \mod \langle \varphi \rangle) \) the projection QLBA \rightarrow LBA; it is such that \( \mu, \delta, \varphi \mapsto \mu, \delta, 0 \).

### 3.3. Quantization functors of Lie bialgebras.

**Definition 3.1.** A quantization functor (QF) of Lie bialgebras is a bialgebra structure \((m, \Delta, \eta, \epsilon)\) on \(S\) in LBA, such that:

(a) its reduction modulo \(\langle \mu, \delta \rangle\) is the standard bialgebra structure on \(S\) in \textbf{Sch} = LBA/\langle \mu, \delta \rangle;

(b1) \(id^{\otimes 2} \to S^{\otimes 2} m \to S \to id) = \mu + \text{terms with total degree } \geq 2, \text{ and}

(b2) \(id \to S \xrightarrow{\Delta} \mu, S^{\otimes 2} \to id^{\otimes 2}) = \delta + \text{terms with total degree } \geq 2.

One checks that \( \text{Ker}(\text{Aut}_{LBA}(S) \to \text{Aut}_{\text{Sch}}(S)) \) (where the map is \( \mu, \delta \mapsto 0 \)) acts on the set of QFs of Lie bialgebras; quantization functors which are related by this action will be called equivalent.

Now view \( C := \text{LBA} \) as graded by \( \deg \). Then \( C_{\leq 0} = \text{LA} \), and \((\text{id}, \mu)\) is a Lie algebra in \( C_{\leq 0} \). We consider QUE algebras in LBA, quantizing \( U(\text{id}_{\text{LA}}) \) (the index emphasizes that this is a bialgebra in LA), and satisfying condition (b2) above. The group \( \text{Ker}(\text{Aut}_{LBA}(S) \to \text{Aut}_{\text{LA}}(S)) \) acts on this set of QUE algebras.

**Proposition 3.1.** The natural map \{quantizations of \( U(\text{id}_{\text{LA}}) \) satisfying (b2)\}/(equivalence) \( \to \) \{QFs of Lie bialgebras\}/(equivalence) is a bijection.

**Proof.** We have:

**Lemma 3.1.** If \( X \) is any Schur functor and \( n \geq 0 \), then the map \( \text{Sch}(S^n, X) \to \text{LA}(S^n, X) \) is bijective.

**Proof.** It suffices to prove this for \( X = T_m \). When \( m = 1 \), we have \( \text{LA}(S^n, \text{id}) = \text{LA}(T_n, \text{id})^{S_n} \) and \( \text{LA}(T_n, \text{id}) \) is the space \( L_n \) of multilinear Lie words in \( n \) letters \( x_1, ..., x_n \); as an \( S_n \)-module, this is a submodule of the space \( A_n \) of multilinear associative words in these letters; as \( A_n \) identifies with the regular representation of \( S_n \), \( A_n^{S_n} \) is 1-dimensional, spanned by \( \sum_{\sigma \in S_n} x_{\sigma(1)} \cdots x_{\sigma(n)} \), which is not in \( L_n \) unless \( n = 1 \); hence

\[
\text{LA}(S^n, \text{id}) = L_n^{S_n} = \left\{ \begin{array}{ll} k & \text{if } n = 1 \\ 0 & \text{else} \end{array} \right\} = \text{Sch}(S^n, \text{id}).
\]

In general,

\[
\text{LA}(S^n, T_m) = \text{LA}(T_n, T_m)^{S_n} = \bigoplus_{(n_1, ..., n_m) : \sum_i n_i = n} \bigotimes_{i=1}^{m} \text{LA}(T_{n_i}, \text{id})^{S_{n_i}} = \text{Sch}(T_{n_i}, \text{id})^{S_{n_i}} = \text{Sch}(S^n, T_m),
\]
where the second equality uses the fact that $\text{LA}(T_n, T_m)$ identifies with

$$\bigoplus_{(n_1, \ldots, n_m) | \sum_i n_i = n} \text{Ind}_{S_{n_1} \times \ldots \times S_{n_m}}^S (\bigotimes_{i=1}^m \text{LA}(T_n, \text{id}))$$

as an $S_n$-module, and the third equality uses the already treated case $m = 1$. □

**Lemma 3.2.** Let $\tilde{m} \in \text{LA}(S^\otimes 2, S)$ be such that $(\tilde{m}, \Delta_0)$ is a bialgebra structure on $S$ in $\text{LA}$. Then for some $s \in k$, $\tilde{m} = s\text{id}, \Delta_0$ (see Section 2.4).

Proof. It follows from its compatibility with $\Delta_0$ that $\tilde{m}$ is uniquely determined by the compositions $\tilde{m}_{ab} = (S^a \otimes S^b \rightarrow S^\otimes 2 \rightarrow S \rightarrow \text{id})$. Each $\tilde{m}_{ab}$ identifies with a multilinear Lie polynomial in two sets of free variables $(x_a)_{a=1}^\mu$, symmetric in each set of variables, hence with a Lie polynomial $p_{a,b}(x, y)$ in two free variables $x, y$, of degree $a$ in $x$ and $b$ in $y$. The associativity condition is translated as $p(p(x, y), z) = p(x, p(y, z))$, where $p(x, y) = \sum_{a,b \geq 0} p_{a,b}(x, y)$. According to [AT], Prop. 2.1, this implies that $p(x, y) = x + y$ or $p(x, y) = s^{-1}c(sx, sy)$ for $s \in k^\times$, which implies that $\tilde{m} = m_{\text{id}, 0}$ in the first case and $\tilde{m} = m_{\text{id}, s}$ in the second case. □

Lemma 3.1 implies that $\text{Aut}_{\text{LA}}(S) \rightarrow \text{Aut}_{\text{Sch}}(S)$ (where the map is induced by $\mu \mapsto 0$) is bijective, so Ker($\text{Aut}_{\text{QLBA}}(S) \rightarrow \text{Aut}_{\text{LA}}(S)$) $\rightarrow$ Ker($\text{Aut}_{\text{QLBA}}(S) \rightarrow \text{Aut}_{\text{Sch}}(S)$) is bijective.

Now let $(m, \Delta)$ be a QF for Lie bialgebras, and let $\tilde{m}, \tilde{\Delta}$ be the reductions of $m, \Delta$ mod $(\delta)$ (these are morphisms in $\text{LA}$). Lemma 3.1 then implies that $\tilde{\Delta} = \Delta_0$, which using Lemma 3.1 and $(\text{id}^\otimes 2 \rightarrow S^\otimes 2 \rightarrow \tilde{m} \rightarrow \text{id} \rightarrow S)$ = $\mu$ implies that $(\tilde{m}, \tilde{\Delta})$ coincides with the morphisms of $U(\text{id}_{\text{LA}})$. So (quantizations of $U(\text{id}_{\text{LA}})$ satisfying (2b)) $\rightarrow$ {QFs of Lie bialgebras} is bijective. This ends the proof of Proposition 3.1. □

**Remark 1.** A QF of Lie bialgebras yields a functor $Q : \{\text{Lie bialgebras over } k\} \rightarrow \{\text{QUE algebras over } k\}$ by $(a, \mu, \delta, \beta) \mapsto (S(a)[[h]],$ the maps obtained from $m, \Delta, ...$ by the substitution $(\mu, \delta) \mapsto (h\mu, h\delta)$). It also yields a functor $Q' : \{\text{Lie bialgebras over } k\} \rightarrow \{\text{quantized formal series Hopf algebras by } a \mapsto (S(a)[[h]],$ the maps obtained by $(\mu, \delta) \mapsto (h\mu, h\delta))$. Then $Q(a)$ and $Q'(a)$ are related by the QUE algebra-QFSh algebra correspondence (Dr1, Gav).

### 3.4. Quantization functors of quasi-Lie bialgebras.

**Definition 3.2.** A QF of quasi-Lie bialgebras is a quasi-bialgebra structure $(m, \Delta, \Phi, \eta, \epsilon)$ on $S$ in $\text{QLBA}$, such that:

(a) its reduction modulo $(\mu, \delta, \phi)$ is the standard quasi-bialgebra structure on $S$ in $\text{Sch}$;

(b1) $(\text{id}^\otimes 2 \rightarrow S^\otimes 2 \rightarrow S \rightarrow \text{id}) = \mu + \text{terms with } \deg_\mu + \deg_\delta \geq 2$;

(b2) $(\text{id} \rightarrow S \rightarrow S^\otimes 2 \rightarrow \text{id}^\otimes 2) = \delta + \text{terms with } \deg_\mu + \deg_\delta \geq 2$;

(b3) $(1 \overset{\text{Alt}^2}{\otimes} S^\otimes 3 \rightarrow S^\otimes 3 \rightarrow \text{id}^\otimes 3) = \phi + \text{terms with } \deg_\mu + \deg_\delta \geq 2$.

As above, one checks that Ker($\text{Aut}_{\text{QLBA}}(S) \rightarrow \text{Aut}_{\text{Sch}}(S)$) acts on the set of QFs of quasi-Lie bialgebras; quantization functors which are related by this action will be called equivalent. A QF for quasi-Lie bialgebras being fixed, one checks that its twist by an element of $\text{LBA}(1, S^\otimes 2)^\times$ is again a QF of quasi-Lie bialgebras.
Now view $\mathcal{C} = \text{QLBA}$ as graded by $\deg$. Then $C_{\leq 0} = \text{LA}$. We consider QHQUE algebras in $\text{QLBA}$ quantizing $U(\text{id}_{\text{LA}})$, and satisfying conditions (b2), (b3) above. Such an element being fixed, its twist by an element of $\text{QLBA}(1, S^{\otimes 2}) \times$ again satisfies (b2), (b3). The group $\text{Ker}(\text{Aut}_{\text{QLBA}}(S) \to \text{Aut}_{\text{LA}}(S))$ acts on this set of QHQUE algebras.

**Proposition 3.2.** The natural map $\{\text{QHQUE algebras quantizing } U(\text{id}_{\text{LA}}) \text{ satisfying (b2), (b3)}\}/(\text{twists, equivalence}) \to \{\text{QFs for quasi-Lie bialgebras}\}/(\text{twists, equivalence})$ is a bijection.

**Proof.** The proof is similar to that of Proposition 3.1. One also has to show that for $(m, \ldots, \Phi)$ a QF of quasi-Lie bialgebras, $(\text{Alt}_3 \circ \Phi) = 0$, where the index 1 means the degree 1 part for $\deg$. Linearizing the pentagon identity satisfied by $\Phi$, we get $(\Delta_1 \circ \text{id}^{\otimes 2} - \text{id} \otimes \Delta_0 \otimes \text{id} + \text{id}^{\otimes 2}) \circ \Phi_1 = \eta \otimes \Phi_1 + \Phi_1 \otimes \eta$. According to [Dr2], Prop. 2.2, this implies that $\text{Alt}_3 \circ \Phi_1$ belongs to the image of $\text{QLBA}(1, \Lambda^3) \to \text{QLBA}(1, S^{\otimes 3})$. We now show that an element of $\text{QLBA}(1, \Lambda^3)$ with $\deg = 1$ necessarily vanishes. More generally, $\text{QLBA}(1, X)_{\leq 1} = 0$ if $|X| \neq 0$, because this space is linearly spanned by compositions of $\mu, \delta, \varphi$, with at least one $\varphi$, as this is the only generator with source 1, and $\deg(\varphi) = 2$. It follows that $(\text{Alt}_3 \circ \Phi_1) = \text{Alt}_3 \circ \Phi_1 = 0$.

**Proposition 3.3.** There is a unique map $\{\text{QFs of quasi-Lie bialgebras}\} \to \{\text{QFs of Lie bialgebras}\}$ such that $(m, \ldots, \Phi) \mapsto (m \mod \langle \varphi \rangle, \ldots, \eta \mod \langle \varphi \rangle)$. It induces a map $\{\text{QFs of quasi-Lie bialgebras}\}/(\text{twists, equivalence}) \to \{\text{QFs of Lie bialgebras}\}/(\text{equivalence})$.

**Proof.** $(m \mod \langle \varphi \rangle, \ldots, \Phi \mod \langle \varphi \rangle)$ clearly satisfies the quasi-bialgebra axioms. Moreover, $\text{LBA}(1, S^{\otimes 3}) = k\eta^{\otimes 3}$, which implies that $(\Phi \mod \langle \varphi \rangle) = \eta^{\otimes 3}$. So $(m \mod \langle \varphi \rangle, \ldots, \eta \mod \langle \varphi \rangle)$ satisfies the bialgebra axioms. The fact that $(m, \ldots, \Phi)$ satisfies (a)-(b2) in Definition 3.1 implies that $(m \mod \langle \varphi \rangle, \ldots, \eta \mod \langle \varphi \rangle)$ satisfies (a)-(b2) in Definition 3.1. We also have $\text{LBA}(1, S^{\otimes 2}) = k\eta^{\otimes 2}$, which implies that the images of twists under $x \mapsto (x \mod \langle \varphi \rangle)$ are trivial.

**Remark 2.** As above, a QF of quasi-Lie bialgebras yields a functor $\{\text{quasi-Lie bialgebras over } k\} \to \{\text{QHQUE algebras}\}$ by $(a, \mu_a, \delta_a, \varphi_a) \mapsto Q(a) := (S(a)[\hbar], \text{the morphisms derived from } m, \ldots, \Phi \text{ by the substitution } (\mu, \delta, \varphi) \mapsto (\mu_a, \delta_a, h^2 \varphi_a))$.

### 3.5. Deformation complexes

Recall that the props $\text{LBA}$ and $\text{QLBA}$ are $\mathbb{N}$-graded by $\deg$. As in Section 2.1 this gives rise to props $\text{LBA}_{\leq n}$, $\text{QLBA}_{\leq n}$.

**Proposition 3.4.** The obstruction to lifting a QUE algebra in $\text{LBA}_{\leq n}$ (resp., a QHQUE algebra in $\text{QLBA}_{\leq n}$) quantizing $U(\text{id}_{\text{LA}})$ to $\text{LBA}_{\leq n+1}$ (resp., to $\text{QLBA}_{\leq n+1}$) belongs to $H^4_{\text{LBA}(n+1)}$ (resp., to $H^4_{\text{QLBA}(n+1)}$). If this obstruction vanishes, possible lifts are parametrized, modulo equivalence (resp., and lifts), by $H^3_{\text{LBA}(n+1)}$ (resp., by $H^3_{\text{QLBA}(n+1)}$). Here

$$H^4_{\text{LBA}} = \bigoplus_{p+q+1} H^q_{\text{C}(\text{id}, \Lambda^p)},$$

for $\mathcal{C} = (\text{Q})\text{LBA}$ (the index $\mathcal{C}$ emphasizes the dependence of the groups defined in Section 2.10 in the ambient symmetric monoidal category), with grading induced by $\deg$.

In particular, the prop morphism $\text{QLBA} \to \text{LBA}$ induces a degree zero linear map $H^4_{\text{QLBA}} \to H^4_{\text{LBA}}$. 

License or copyright restrictions may apply to redistribution; see https://www.ams.org/journal-terms-of-use
Proof. The statement follows from Section 2.6 in the case of the quantization problem in QLBA. In the case of LBA, the relevant cohomology groups are, according to Section 2.6

\[
H^i_{LBA} = \bigoplus_{p+q=i, p>0, q \geq 0} H^p_{LBA}^q, \quad \text{where} \quad H^p_{LBA}^q = \begin{cases} H^p_{LBA}(id, \Lambda^p) & \text{if } q > 1, \\ Z_{LBA}^1(id, \Lambda^p) & \text{if } q = 1, \\ 0 & \text{if } q = 0. \end{cases}
\]

Now \( C^0_{LBA}(id, \Lambda^p) = LBA(1, \Lambda^p) = 0 \) as \( p > 0 \), which implies that \( H^0_{LBA}(id, \Lambda^p) = 0 \) and \( H^1_{LBA}(id, \Lambda^p) = Z^1_{LBA}(id, \Lambda^p) \). Therefore \( H^p_{LBA}^q(id, \Lambda^p) = H^p_{LBA}(id, \Lambda^p) \) for any \( p > 0, q \geq 0 \), as wanted.

\[\square\]

4. THE MAIN RESULT

The main result of our paper is:

Theorem 4.1. The map \( \{\text{QFs of quasi-Lie bialgebras}\}/(\text{twists, equivalence}) \to \{\text{QFs of Lie bialgebras}\}/(\text{equivalence, twists}) \) (see Proposition 3.3) is a bijection.

Its proof is based on

Theorem 4.2. For any \( i \geq 0 \), the map \( H^i_{QLBA} \to H^i_{LBA} \) is a graded isomorphism.

Theorem 4.2 will be proved in Sections 5 and 6. In the rest of the present section, we prove that Theorem 4.2 implies Theorem 4.1.

Set \( Q_n := \{\text{bialgebra structures } (m, \Delta) \text{ on } S \text{ in } LBA_{\geq n} \} \), such that \( m \equiv m_{id,m} \mod LBA_{\geq 1}, \Delta \equiv \Delta_0 \mod LBA_{\geq 1} \), and \( (id \to S) = S \to \Lambda^2 \to \Theta^2 \to \text{id}^2 \equiv \delta \mod LBA_{\geq 2} \). \( Q_n := \{\text{quasi-bialgebra structures } (m, \Delta, \Phi) \text{ on } S \text{ in } QLBA_{\leq n} \}, \) satisfying the same conditions (replacing LBA by QLBA). Here we denote by \( (Q)\text{LBA}_{\geq n+1} \) the proper ideal \( \text{Ker}((Q)\text{LBA} \to (Q)\text{LBA}_{\leq n}) \) and \( m_{id,m} \in \text{LA}(S^2, S) \) is as in Section 2.4.

We have projection maps \( \tilde{Q}_{n+1} \to \tilde{Q}_n \), and the projective limit \( \tilde{Q}_\infty := \lim_{\leftarrow} Q_n \) identifies with \( \{\text{QFs of Lie bialgebras}\}/(\text{equivalence}) \). Similarly, we have natural maps \( \tilde{Q}_{n+1} \to \tilde{Q}_n \). To show that the projective limit \( \tilde{Q}_\infty := \lim_{\leftarrow} \tilde{Q}_n \) identifies with \( \{\text{QFs of quasi-Lie bialgebras}\}/(\text{equivalence, twists}) \), we note that (a) if \( (m, \Delta, \Phi) \in \tilde{Q}_\infty \), then \( \text{Alt}_3 \circ \Phi_1 = 0 \) (see proof of Proposition 4.2), and (b) the pentagon identity then implies that \( \text{Alt}_3 \circ \Phi_2 \in QLBA(1, \Lambda^3) \), so \( \text{Alt}_3 \circ \Phi_2 \) is proportional to \( \varphi \); if now \( \delta := \Delta - \beta \circ \Delta \), then \( \text{Alt}_3 \circ (\beta \circ \text{id}_S) \circ \delta = 2 \text{Alt}_3 \circ (\text{id}_{S^2} - \Phi \circ \text{id}_{S^2} - \Phi^{-1}) \circ \Delta^2 \), restricting to \( \text{id} \) and retaining only the terms in degree 2, we get \( \text{Alt}_3 \circ (\delta \circ \text{id}_{id}) \circ \delta = \text{Alt}_3 \circ (\mu \circ \text{id}_{id}) \circ (\text{id}_{id} \circ (\text{id}_S \circ \varphi)) \), which implies, given that the same identity holds with \( \varphi \) in place of \( \text{Alt}_3 \circ \Phi_2 \), the equality \( \text{Alt}_3 \circ \Phi_2 = \varphi \).

We also have a reduction map \( \tilde{Q}_n \to Q_n \), compatible with the above projections. We will show that for any \( n \geq 0 \), this map is a bijection. When \( n = 0 \), this is clear as \( QLBA_{\leq 0} = LBA_{\leq 0} \). Assume that we have proved that \( \tilde{Q}_n \to Q_n \) is a bijection.

For \( q \in Q_n \), let \( \tilde{q} \) be its preimage in \( \tilde{Q}_n \). The obstruction to lifting \( q \) to \( \tilde{Q}_{n+1} \) (resp., \( \tilde{q} \) to \( \tilde{Q}_{n+1} \)) is a class \( \text{obs}(q) \in H^4_{QLBA}[n+1] \) (resp., \( \text{obs}(\tilde{q}) \in H^4_{QLBA}[n+1] \)). These classes are mapped to each other under \( H^4_{QLBA}[n+1] \to H^4_{QLBA}[n+1] \), so Theorem 4.2 implies that \( \text{obs}(q) = 0 \) iff \( \text{obs}(\tilde{q}) = 0 \); in other terms, the bijection \( \tilde{Q}_n \to Q_n \) restricts to a bijection between \( \text{image}(\tilde{Q}_{n+1} \to Q_n) \) and \( \text{image}(Q_{n+1} \to Q_n) \). To complete the proof, it remains to show that for any \( q \in \text{image}(Q_{n+1} \to Q_n) \), the map \( \tilde{Q}_{n+1} \to Q_{n+1} \) induces a bijection \( \pi_{n+1}^{-1}(\tilde{q}) \to \pi_n^{-1}(q) \). These fibers are affine.
spaces over $H^3_{QLBA}[n+1]$ and $H^3_{LBA}[n+1]$, and the map between them is a morphism of affine spaces, compatible with the natural map $H^3_{QLBA}[n+1] \to H^3_{LBA}[n+1]$. Theorem 4.2 says that this map is an isomorphism; therefore the map $\tilde{\pi}^{-1}_n(\hat{q}) \to \pi_n^{-1}(\hat{q})$ is a bijection, as wanted.

5. Structure of the prop QLBA

In order to establish Theorem 4.2, we study the structure of QLBA.

5.1. Products of ideals in props. If $C$ is a prop and $I_1, ..., I_n$ are ideals of $C$, then the product $I_1 ... I_n$ is the smallest ideal containing the morphisms $f_1 * ... * f_n$, where $f_i$ is a morphism in $I_i$ and $*$ is $\circ$ or $\otimes$. One defines in this way the powers $I^n$ of an ideal.

5.2. Structure of the prop LBA. Define $LA$ (resp., $LCA$) as the prop generated by $\mu \in LA(id^{\otimes 2}, id)$ subject to the antisymmetry and Jacobi relation (resp., $\delta \in LCA(id, id)^{\otimes 2}$ subject to antisymmetry and the co-Jacobi relation). We have prop morphisms $LA, LCA \to LBA$. The structure of LBA is given by

Proposition 5.1. For $(X_i)_{i \in I}$, $(Y_j)_{j \in J}$ finite families of objects in $\text{Ob}(\text{Sch})$, we have an isomorphism

$$\text{LBA}(\bigotimes_{i} X_i, \bigotimes_{j} Y_j) \simeq \bigoplus_{(Z_{ij}) \in \text{Irr}(\text{Sch})} \bigotimes_{i} (\text{LCA}(X_i, \bigotimes_{j} Z_{ij})) \otimes \bigotimes_{j} (\text{LA}(\bigotimes_{i} Z_{ij}, Y_j)),$$

whose inverse is the direct sum of the maps $(\bigotimes, c_i) \otimes (\bigotimes, a_j) \mapsto (\bigotimes, a_j) \circ \beta_1, j \circ (\bigotimes, c_i)$, where $\beta_1, j : \bigotimes_i (\bigotimes_j Z_{ij}) \to \bigotimes_j (\bigotimes_i Z_{ij})$ is the braiding morphism.

This is proved in [E, Pos]; see also Appendix A.

5.3. A filtration on QLBA. Let $\langle \varphi \rangle$ be the prop ideal of QLBA generated by $\varphi$ and denote by $\langle \varphi \rangle^n$ its $n$th power. For $X, Y \in \text{Ob}(\text{Sch})$, we have a decreasing filtration $\text{QLBA}(X, Y) \supset \langle \varphi \rangle(X, Y) \supset \langle \varphi \rangle^2(X, Y) \supset ...$. As $\varphi$ is homogeneous for the $\mathbb{Z}^2$-grading, so are the $\langle \varphi \rangle^n$, i.e., $\langle \varphi \rangle^n(X, Y) = \bigoplus_{\alpha \in \mathbb{Z}^2} \langle \varphi \rangle^n(X, Y)[\alpha]$.

Lemma 5.1. This filtration is complete, i.e., $\bigcap_{n \geq 0} \langle \varphi \rangle^n(X, Y) = 0$.

Proof: Observe that $\langle \varphi \rangle^n(X, Y)$ is supported in $n(-1, 2) + N(1, 0) + N(0, 1) + N(-1, 2) \subset \langle 2n + N \rangle(0, 1) + \mathbb{Z}(1, 0)$. Then $\bigcap_{n \geq 0} \langle \varphi \rangle^n(X, Y)$ is supported in $\bigcap_{n \geq 0} \langle 2n + N \rangle(0, 1) + \mathbb{Z}(1, 0)$, which is empty. So this intersection is zero. \qed

The composition of QLBA restricts to a map $\langle \varphi \rangle^m(G, H) \otimes \langle \varphi \rangle^n(F, G) \to \langle \varphi \rangle^{n+m}(F, H)$, and the tensor product restricts to $\langle \varphi \rangle^n(F, G) \otimes \langle \varphi \rangle^n(F', G') \to \langle \varphi \rangle^{n+n'}(F \otimes F', G \otimes G')$, so $\text{QLBA} \supset \langle \varphi \rangle \supset ...$ is a prop filtration. The associated graded prop is defined by $\text{gr } \text{QLBA}(F, G) := \bigoplus_{n \geq 0} \text{gr}_n \text{QLBA}(F, G)$, where $\text{gr}_n \text{QLBA}(F, G) = \langle \varphi \rangle^n(F, G)/\langle \varphi \rangle^{n+1}(F, G)$.
5.4. **The graded prop** $\text{LBA}_\alpha$. Define $P$ to be the prop with the same generators $\bar{\mu}, \bar{\delta}, \bar{\varphi}$ as $\text{QLBA}$ and the same relations, except for the third, which is replaced by $\text{Alt}_3 \circ (\delta \otimes \text{id}_{\text{id}}) \circ \delta = 0$.

We now construct a prop isomorphic to $P$. The following general construction goes back to [EH]. For $C \in \text{Ob}(\text{Sch})$, we have a prop $\text{LBA}_C$ defined by $\text{LBA}_C(F,G) := \bigoplus_{n \geq 0} \text{LBA}(F \otimes S^n(C), G)$ (the composition is induced by the coproduct $S \to S^{\otimes 2}$). For $D \in \text{Ob}(\text{Sch})$, we set $\text{LBA}_{C,D}(F,G) := \bigoplus_{n \geq 0} \text{LBA}(F \otimes S^n(C) \otimes D, G)$; for $\alpha \in \text{LBA}(C,D)$, we have a map $\text{LBA}(F \otimes S^n(C) \otimes D, G) \to \text{LBA}(F \otimes S^{n+1}(C), G)$, $x \mapsto x \circ (\text{id}_F \otimes S^n(C) \otimes \alpha) \circ (\text{id}_F \otimes \Delta_{n,1})$, where $\Delta_{n,1} : S^{n+1}(C) \to S^n(C) \otimes C$ is the component $n+1 \to (n,1)$ of the coproduct $S(C) \to S(C)^{\otimes 2}$. Then we have commutative diagrams

\[
\begin{align*}
\text{LBA}_{C,D}(F,G) \otimes \text{LBA}_C(G,H) &\rightarrow \text{LBA}_{C,D}(F,H) \\
\oplus \text{LBA}_C(F,G) \otimes \text{LBA}_{C,D}(G,H) &\rightarrow \text{LBA}_C(F,H)
\end{align*}
\]

and

\[
\begin{align*}
\text{LBA}_{C,D}(F,G) \otimes \text{LBA}_C(F',G') &\rightarrow \text{LBA}_{C,D}(F \otimes F', G \otimes G') \\
\oplus \text{LBA}_C(F,G) \otimes \text{LBA}_{C,D}(F',G') &\rightarrow \text{LBA}_C(F \otimes F', G \otimes G')
\end{align*}
\]

induced by the composition and tensor product, which implies that if $\text{LBA}_\alpha(F,G) := \text{Coker}(\text{LBA}_{C,D}(F,G) \to \text{LBA}_C(F,G))$,

then we have a prop morphism $\text{LBA}_C \to \text{LBA}_\alpha$.

In what follows, we will set $C := A^3$, $D := A^4$, $\alpha := \text{pr}_4 \circ \text{Alt}_4 \circ (\delta \otimes \text{id}_{\text{id}}) \circ \text{inj}_3 \in \text{LBA}(A^3,A^4)$, where $\text{inj}_3 : A^3 \to \text{id}^{\otimes 3}$ and $\text{pr}_4 : \text{id}^{\otimes 4} \to A^4$ are the canonical injection and projection.

**Lemma 5.2.** We have a prop isomorphism $\text{LBA}_\alpha \simeq P$.

**Proof.** Let $\tilde{P}$ be the prop with generators $\bar{\mu}, \bar{\delta}, \bar{\varphi}$ and the following relations: Lie bialgebra relations between $\bar{\mu}, \bar{\delta}$, and $\bar{\varphi} = \frac{1}{6} \text{Alt}_3 \circ \bar{\varphi}$. We have a morphism $\tilde{P} \to \text{LBA}_{A^3}$, defined by $\bar{\mu} \mapsto \mu \in \text{LBA}(\text{id}^{\otimes 2} \otimes S^0(\Lambda^3), \text{id}) \subset \text{LBA}_{A^3}(\text{id}^{\otimes 2}, \text{id})$; $\bar{\delta} \mapsto \delta \in \text{LBA}(\text{id} \otimes S^0(\Lambda^3), \text{id}^{\otimes 2}) \subset \text{LBA}_{A^3}(\text{id}, \text{id}^{\otimes 2})$; $\bar{\varphi} \mapsto \text{inj}_3 \in \text{LBA}(1 \otimes S^1(\Lambda^3), \text{id}^{\otimes 3}) \subset \text{LBA}_{A^3}(1, \text{id}^{\otimes 3}$, as $\text{inj}_3 = \frac{1}{6} \text{Alt}_3 \circ \text{inj}_3$. We also have a morphism $\text{LBA}_{A^3} \to \tilde{P}$, defined by $\text{LBA}_{A^3}(F,G) \supset \text{LBA}(F \otimes S^n(\Lambda^3), G) \ni f \mapsto \text{can}(f) \circ (\text{id}_F \otimes S^n(\bar{\varphi})) \in \tilde{P}(F,G)$, where can : $\text{LBA} \to \tilde{P}$ is the prop morphism defined by $\mu, \delta \mapsto \bar{\mu}, \bar{\delta}$.

One proves that these are inverse isomorphisms, which induce an isomorphism $\text{LBA}_\alpha \simeq P$. \hfill \Box

5.5. **A graded prop morphism** $\text{LBA}_\alpha \to \text{gr} \text{QLBA}$.

**Lemma 5.3.** There is a unique prop morphism $\text{LBA}_\alpha \simeq P \to \text{gr} \text{QLBA}$, defined by $P(\text{id}^{\otimes 2}, \text{id}) \ni \bar{\mu} \mapsto \mu \in \text{gr}_0 \text{QLBA}(\text{id}^{\otimes 2}, \text{id}) = \text{gr}_0 \text{QLBA}(\text{id}^{\otimes 2}, \text{id})$, $P(\text{id}, \text{id}^{\otimes 2}) \ni \bar{\delta} \mapsto \delta \in \text{gr}_0 \text{QLBA}(\text{id}, \text{id}^{\otimes 2}) = \text{gr}_0 \text{QLBA}(\text{id}, \text{id}^{\otimes 2})$ (we have $\text{QLBA} / (\bar{\varphi}) = \text{LBA}$, so $\text{gr}_0 \text{QLBA} = \text{LBA}$), $P(1, \text{id}^{\otimes 3}) \ni \bar{\varphi} \mapsto [\varphi] \in \text{gr}_1 \text{QLBA}(1, \text{id}^{\otimes 3})$.

**Proof.** The images in $\text{gr}_0 \text{QLBA}$ of the Jacobi relation for $\mu$, of the cocycle relation between $\mu, \delta$, and of the quasi-co-Jacobi relation between $\mu, \delta, \varphi$ (which hold in
The images in \( \text{gr}_1 \) of the relations \( \varphi = \frac{1}{6} \operatorname{Alt}_3 \circ \varphi \) and \( \operatorname{Alt}_4 \circ (\delta \otimes \text{id}_{id}^2) \circ \varphi = 0 \) (which hold in \( \langle \varphi \rangle \)) are the similar relations, with \( \delta, \varphi \) replaced by \([\delta], [\varphi] \). It follows that we have a prop morphism \( P \to \text{gr} Q\text{LBA}, [\mu], [\delta], [\varphi]. \)

**Theorem 5.1.** The prop morphism \( \text{LBA}_\alpha \to \text{gr} Q\text{LBA} \) is a prop isomorphism.

**Proof.** We say that a prop morphism \( C \to D \) is surjective (resp., injective) if the maps \( C(F, G) \to D(F, G) \) are.

As \( Q\text{LBA} \) is generated by \( [\mu], [\delta], [\varphi] \), the prop \( Q\text{LBA} \) is generated by their classes \( [\mu], [\delta], [\varphi] \), and since the generators of \( P \simeq \text{LBA}_\alpha \) map to these elements, the morphism \( \text{LBA}_\alpha \to \text{gr} Q\text{LBA} \) is surjective.

We now prove the injectivity of \( \text{LBA}_\alpha \to \text{gr} Q\text{LBA} \). Let us first explain the main points of this proof. We construct a filtered prop morphism \( Q\text{LBA} \to L(\text{LCA}_{\Lambda^2}) \); composing the associated graded morphism \( \text{gr} Q\text{LBA} \to L(\text{LCA}_{\Lambda^2}) \) with \( \text{LBA}_\alpha \to \text{gr} Q\text{LBA} \), we obtain a morphism \( \text{LBA}_\alpha \to L(\text{LCA}_{\Lambda^2}) \). This morphism factors as \( \text{LBA}_\alpha \to L(\text{LCA}_\alpha) \to L(\text{LCA}_{\Lambda^2}) \). The injectivity of \( \text{LBA}_\alpha \to L(\text{LCA}_\alpha) \) is a consequence of a general argument (already used in the proof of the structure result for the prop \( \text{LBA} \); see Appendix \( \Lambda \)), while the injectivity of the second morphism follows from that of a morphism \( \text{LCA}_\alpha \to \text{LCA}_{\Lambda^2} \), which is a consequence of Lemma 5.1. This establishes the injectivity of \( \text{LBA}_\alpha \to L(\text{LCA}_\alpha) \) and therefore of \( \text{LBA}_\alpha \to \text{gr} Q\text{LBA} \). Let us now proceed with the details of the proof.

We first define the auxiliary props mentioned above. \( \text{LCA}_{\Lambda^2} \) is the prop with generators \( \delta_{\Lambda^2} : \text{id} \to \text{id} \otimes \text{id}^2, r : 1 \to \text{id} \otimes \text{id}^2 \), and relations: antisymmetry and co-Jacobi for \( \delta_{\Lambda^2} \), and antisymmetry for \( r \). Similarly, \( \text{LCA}_\alpha \) is the prop with generators \( \delta_{\alpha} : \text{id} \to \text{id} \otimes \text{id}^2 \) and \( \tilde{\varphi} : 1 \to \text{id} \otimes \text{id}^3 \), and relations: antisymmetry and co-Jacobi for \( \delta_\alpha \), antisymmetry for \( \tilde{\varphi} \), and \( \operatorname{Alt}_4 \circ (\delta \otimes \text{id}^2_{\text{id}}) \circ \tilde{\varphi} = 0 \). One checks that there are unique \( \text{Sch} \)-props \( \text{LCA}_{\Lambda^2}, \text{LCA}_\alpha \) associated to these props (for example, \( \text{LCA}_{\Lambda^2}(F, G) = \prod_{i,j} \text{LCA}_{\Lambda^2}(F_i, G_j) \) for \( F = \bigoplus_i F_i, G = \bigoplus_j G_j \)). We denote by \( L \in \text{Ob}(\text{Sch}) \) the “free Lie algebra” Schur functor, i.e., if \( V \) is a vector space, then \( L(V) \) is the free Lie algebra generated by \( V \); so \( L = L_1 \oplus L_2 \oplus \ldots \), where \( L_1 = \text{id}, L_2 = \Lambda^2, \) etc.

We now define the prop morphism \( Q\text{LBA} \to L(\text{LCA}_{\Lambda^2}) \). The universal version of the Lie algebra bracket on \( L(V) \) is an element \( \mu_{\text{free}} \in \text{Sch}(L \otimes^2, L) \). The prop morphism \( Q\text{LBA} \to L(\text{LCA}_{\Lambda^2}) \) is then defined by \( \mu \mapsto \mu_{\text{free}}, \delta \mapsto \delta_{\text{free}} + \text{ad}(r), \varphi \mapsto \frac{1}{2} \operatorname{Alt}_3 \circ ((\delta_{\text{free}} \otimes \text{id}_L) \circ \tilde{r} - (\text{id}_L \otimes \mu_{\text{free}}) \circ (\text{id}_L \otimes \delta_{\text{free}} \otimes \text{id}_L) \circ (\tilde{r} \otimes \tilde{r}) ) \) where we identify \( \delta_{\text{free}} \) with its image under \( L(\text{Sch}) \to L(\text{LCA}_{\Lambda^2}) \); we identify \( \delta_{\text{free}} \) with its image under \( L(\text{LCA}) \to L(\text{LCA}_{\Lambda^2}) \) (see Appendix \( \Lambda \)); \( \text{ad}(r) \in \text{LCA}_{\Lambda^2}(L, L \otimes^2) \) is \( (\text{id}_L \otimes \mu_{\text{free}}) \circ (\delta_{\text{free}} \otimes r) \circ (\delta_{\text{free}} \otimes r) \); \( \tilde{r} = \text{inj}_1^2 \circ r \), where \( \text{inj}_1^2 : \text{id} \to L \) is the canonical injection. This morphism is the propic version of the following construction: to a Lie coalgebra \((c, \delta_c)\) and \( r_e \in \Lambda^2(c) \), we associate the quasi-Lie bialgebra defined as the twist by \( \Lambda^2(\text{inj}_1^2)(r_e) \) of the Lie bialgebra \((L(c), \delta_L(c))\), where \( \delta_{L(c)} : L(c) \to L(c) \otimes^2 \) is the unique derivation extending \( \delta_e \) (and \( \text{inj}_1^2 : c \to L(c) \) is the canonical injection).

The powers of the prop ideal \( \langle r \rangle \) define a filtration on the prop \( \text{LCA}_{\Lambda^2} \); the associated graded prop \( \text{gr} \text{LCA}_{\Lambda^2} \) is canonically isomorphic to \( \text{LCA}_{\Lambda^2} \). The prop morphism \( Q\text{LBA} \to L(\text{LCA}_{\Lambda^2}) \) is compatible with the filtrations (as it takes \( \varphi \) to \( \langle r \rangle \)), and the associated graded morphism \( \text{gr} Q\text{LBA} \to L(\text{LCA}_{\Lambda^2}) \) is given by...
\( [\mu] \mapsto \mu_{\text{free}}, \ [\delta] \mapsto \delta_{\text{free}} \) and \( [\varphi] \mapsto \frac{1}{2} \text{Alt}_3 \circ (\delta_{\text{free}} \otimes \text{id}_L) \circ \text{inj}^{\otimes 2}_1 \). The composed morphism

\[
(2) \quad \text{LBA}_\alpha \to \text{grQLBA} \to L(\text{LCA}_{\Lambda^2})
\]

is then given by \( \tilde{\mu} \mapsto \mu_{\text{free}}, \tilde{\delta} \mapsto \delta_{\text{free}} \) and \( \tilde{\varphi} \mapsto \frac{1}{2} \text{Alt}_3 \circ (\delta_{\text{free}} \otimes \text{id}_L) \circ \text{inj}^{\otimes 2}_1 \).

We now define two prop morphisms \( \text{LBA}_\alpha \to L(\text{LCA}_\alpha) \) and \( \text{LCA}_\alpha \to \text{LCA}_{\Lambda^2} \), such that the above morphism \( \text{LBA}_\alpha \to L(\text{LCA}_{\Lambda^2}) \) coincides with \( \text{LBA}_\alpha \to L(\text{LCA}_\alpha) \to L(\text{LCA}_{\Lambda^2}) \).

First define \( \text{LBA}_\alpha \to L(\text{LCA}_\alpha) \). There is a unique morphism \( \text{LBA} \to L(\text{LCA}) \), taking \( \mu, \delta \) to \( \mu_{\text{free}}, \delta_{\text{free}} \) (see Appendix A): this is the propic version of the functor \( \{\text{Lie coalgebras}\} \to \{\text{Lie bialgebras}\}, (\epsilon, \delta) \mapsto (L(\epsilon), \text{free Lie bracket}, \text{unique co-bracket extending } \delta) \). We define \( \text{LBA}_\alpha \to L(\text{LCA}_\alpha) \) by \( \tilde{\mu}, \tilde{\delta} \mapsto \mu_{\text{free}}, \delta_{\text{free}} \) (we identify \( \mu_{\text{free}}, \delta_{\text{free}} \) with their images in \( L(\text{LCA}_\alpha) \)) and \( \tilde{\varphi} \mapsto \text{inj}^{\otimes 2}_1 \circ \tilde{\varphi} \). This morphism is the propic version of \( \{(\epsilon, \delta, \varphi_\epsilon) (| \epsilon, \delta \rangle) \in \Lambda^3(\epsilon), \text{Alt}_4 \circ (\epsilon \otimes \delta \otimes \text{id}_{\Lambda^2}) (\varphi_\epsilon) = 0 \} \to \{(a, \delta, \varphi) (| a, \delta \rangle) \in \Lambda^3(a), \text{Alt}_4 \circ (\delta \otimes \text{id}_{\Lambda^2}) \circ \varphi = 0 \} \). Extending the above functor by \( \varphi_a := \Lambda^1(\text{inj}_1^1)(\varphi_a) \).

We then define the morphism \( \text{LCA}_\alpha \to \text{LCA}_{\Lambda^2} \) by \( \delta \mapsto \delta_{\text{LCA}}, \tilde{\varphi} \mapsto \frac{1}{2} \text{Alt}_3 (\delta_{\text{LCA}} \otimes \text{id}_{\Lambda^2}) \circ r \). One checks that \( (2) \) coincides with \( \text{LBA}_\alpha \to L(\text{LCA}_\alpha) \to L(\text{LCA}_{\Lambda^2}) \).

Let us prove that \( \text{LBA}_\alpha \to L(\text{LCA}_\alpha) \) is injective. Using the symmetric group actions, this is equivalent to proving that for any \( p, q \geq 0 \), the map

\[
(3) \quad \text{LBA}_\alpha(T_p, T_q) \to \text{LCA}_\alpha(L^{\otimes p}, L^{\otimes q})
\]

is injective.

**Lemma 5.4.** The map \( \bigoplus_{Z \in \text{Irr(Sch)}} \text{LCA}_\alpha(T_p, Z) \otimes \text{LA}(Z, T_q) \to \text{LBA}_\alpha(T_p, T_q) \),

induced by the prop morphisms \( \text{LCA}_\alpha, \text{LA} \to \text{LBA}_\alpha \) \( \delta, \tilde{\varphi} \mapsto \delta, \tilde{\varphi}, \mu \mapsto \tilde{\mu} \) and by composition, is an isomorphism of vector spaces.

**Proof of Lemma.** Recall that \( C = \Lambda^3, D = \Lambda^4, \alpha \in \text{LBA}(D, C) \). One may construct as above a prop \( \text{LCAC} \) by \( \text{LCAC}(F, G) := \bigoplus_{n \geq 0} \text{LCAC}(F \otimes S^n(C), G) \); setting \( \text{LCAC}_{\alpha, D}(F, G) := \bigoplus_{n \geq 0} \text{LCAC}(F \otimes S^n(C) \otimes D, G) \), then using the fact that \( \alpha \in \text{LCA}(D, C) \), one constructs a map \( \text{LCAC}_{\alpha, D}(F, G) \to \text{LCAC}(F, G) \) and one then checks that \( \text{LCAC}(F, G) = \text{Coker} (\text{LCAC}_{\alpha, D}(F, G) \to \text{LCAC}(F, G)) \). For \( F, G \in \text{Ob(Sch)} \), we have a commutative diagram

\[
\begin{array}{ccc}
\bigoplus_{Z \in \text{Irr(Sch)}} \text{LCA}_{\alpha, D}(F, Z) \otimes \text{LA}(Z, G) & \xrightarrow{\gamma} & \text{LBA}_{\alpha, D}(F, G) \\
\downarrow & & \downarrow \\
\bigoplus_{Z \in \text{Irr(Sch)}} \text{LCA}_{\alpha}(F, Z) \otimes \text{LA}(Z, G) & \xrightarrow{\gamma} & \text{LBA}_{\alpha}(F, G)
\end{array}
\]

whose vertical cokernel is an isomorphism

\[
\bigoplus_{Z \in \text{Irr(Sch)}} \text{LCA}_{\alpha}(F, Z) \otimes \text{LA}(Z, G) \xrightarrow{\gamma} \text{LBA}_{\alpha}(F, G);
\]

this isomorphism coincides with the map described in the statement of the lemma. \( \square \)
We now consider the composite map

\[ (4) \bigoplus_{Z \in \text{Irr}(\text{Sch})} \text{LCA}_\alpha(T_p, Z) \otimes \text{LA}(Z, T_q) \to \text{LBA}_\alpha(T_p, T_q) \to \text{LCA}_\alpha(L^{\otimes p}, L^{\otimes q}) \to \text{LCA}_\alpha(T_p, L^{\otimes q}), \]

where the first map is described in Lemma 5.3, the middle map is \( \Box \), and the last map is induced by the injection \( T_p = \text{id}^{\otimes p} \to L^{\otimes p} \).

**Lemma 5.5.** The map \( (4) \) coincides with the composite map \( \bigoplus_Z \text{LCA}_\alpha(T_p, Z) \otimes \text{LA}(Z, T_q) \simeq \bigoplus_Z \text{LCA}_\alpha(T_p, Z) \otimes \text{Sch}(Z, L^{\otimes q}) \to \text{LCA}_\alpha(T_p, L^{\otimes q}) \), where the first map is induced by the isomorphism \( \text{LA}(Z, T_q) \simeq \text{Sch}(Z, L^{\otimes q}) \) and the second by composition.

**Proof.** Note that the isomorphism \( \text{LA}(Z, T_q) \simeq \text{Sch}(Z, L^{\otimes q}) \) is proved in Appendix A. By using symmetric group actions, one shows that it suffices to prove the above statement with \( Z \) replaced by \( T_N \). We have composite prop morphisms \( \rho : \text{LCA}_\alpha \to L(\text{LCA}_\alpha) \) and \( \sigma : \text{LA} \to L(\text{LBA}_\alpha) \); actually \( \sigma \) factors through \( \text{LA} \to L(\text{Sch}) \). The map \( (4) \) (with \( Z \) replaced by \( T_N \)) then takes \( f \otimes g \) to \( \sigma(g) \circ \rho(f) \circ \text{inj}_{1_{\otimes p}} \), where \( \text{inj}_{1_{\otimes p}} : \text{id} \to L \) is the canonical morphism, \( f \in \text{LCA}_\alpha(T_p, T_N) \), \( g \in \text{Sch}(T_N, T_q) \), \( \rho(f) \in \text{LCA}_\alpha(L^{\otimes p}, L^{\otimes N}) \), \( \sigma(g) \in \text{Sch}(L^{\otimes N}, L^{\otimes q}) \).

We have \( \rho(f) \circ \text{inj}_{1_{\otimes p}} = \text{inj}_{1_{\otimes N}} \circ f \), as this property can be checked for \( f = \delta_{\text{LCA}, r} \) and is preserved by composition and tensor products. Moreover, \( \sigma(g) \circ \text{inj}_{1_{\otimes N}} \in \text{LA}(T_N, L^{\otimes N}) \) is the image \( \tilde{g} \) of \( g \) under \( \text{LA}(Z, T_q) \simeq \text{Sch}(Z, L^{\otimes q}) \). It follows that \( (4) \) coincides with \( f \otimes g \mapsto \tilde{g} \circ f \), which was to be proved.

According to Lemma A.1 the composite map \( \bigoplus_Z \text{LCA}_\alpha(T_p, Z) \otimes \text{LA}(Z, T_q) \simeq \bigoplus_Z \text{LCA}_\alpha(T_p, Z) \otimes \text{Sch}(Z, L^{\otimes q}) \to \text{LCA}_\alpha(T_p, L^{\otimes q}) \) is an isomorphism, so Lemma 5.5 implies that the composite map \( (4) \) is an isomorphism. The first map in \( (4) \) is thus also an isomorphism by Lemma 5.3 so the map \( \Box \) is injective, which was to be proved.

Let us now prove that \( \text{LCA}_\alpha \to \text{LCA}_{\alpha^2} \) is injective. For this, we outline the structure of these props. We have

\[
\text{LCA}_{\alpha^2}(T_p, T_z) = \bigoplus_{k \geq 0} \left( \bigoplus_{z', z_1, \ldots, z_k | z' + z_1 + \ldots + z_k = z} \text{Ind}_{\text{Sch}_{z', z_1} \times \text{Sch}_{z_1} \times \ldots \times \text{Sch}_{z_k}} \left( \text{LCA}(T_p, T_{z'}) \otimes \bigotimes_{i=1}^{k} \text{LCA}(\Lambda^2, T_{z_i}) \right) \right) \otimes_{\mathbb{S}^k}.
\]

and

\[
\text{LCA}_\alpha(T_p, T_z) = \bigoplus_{z \geq 0} \left( \bigoplus_{z', z_1, \ldots, z_k | z' + z_1 + \ldots + z_k = z} \text{Ind}_{\text{Sch}_{z', z_1} \times \text{Sch}_{z_1} \times \ldots \times \text{Sch}_{z_k}} \left( \text{LCA}(T_p, T_{z'}) \otimes \bigotimes_{i=1}^{k} \text{Coker} \left( \text{LCA}(\Lambda^4, T_{z_i}) \to \text{LCA}(\Lambda^3, T_{z_i}) \right) \right) \right) \otimes_{\mathbb{S}^k}.
\]

The injectivity of \( \text{LCA}_\alpha \to \text{LCA}_{\alpha^2} \) is therefore equivalent to that of \( \text{Coker}(\text{LCA}(\Lambda^4, T_z) \to \text{LCA}(\Lambda^3, T_z)) \) \( \to \text{LCA}(\Lambda^2, T_z) \); in other terms, we have a sequence

\[
\text{LCA}(\Lambda^4, T_z) \to \text{LCA}(\Lambda^3, T_z) \to \text{LCA}(\Lambda^2, T_z)
\]

where the composite map is zero, and we should prove that the homology vanishes.
To prove this, we will prove that the second homology of the complex

\[ \cdots \to \text{LA}(T_z, \Lambda^4) \xrightarrow{\text{Alt}_3 \circ (\mu \otimes \text{id} \otimes \text{id})} \text{LA}(T_z, \Lambda^3) \xrightarrow{\text{Alt}_2 \circ (\mu \otimes \text{id} \otimes \text{id})} \text{LA}(T_z, \Lambda^2) \to 0 \]

vanishes. We will prove more generally:

**Lemma 5.6.** If \( z \geq 2 \), the complex \( 5 \) is cyclic; if \( z = 1 \), its homology is 1-dimensional, concentrated in degree 0.

**Proof.** Let \( \mathcal{L}_z \) (resp., \( \mathcal{A}_z \)) be the free Lie (resp., associative) algebra with generators \( x_1, \ldots, x_z \). These spaces are both graded by \( \bigoplus_{i=1}^\infty \mathbb{N} \delta_i \), where \( |x_i| = \delta_i \). For \( V \) a vector space graded by \( \bigoplus_{i=1}^\infty \mathbb{N} \delta_i \), and \( \mathbf{I} \subset [1, z] \), we denote by \( V_{\mathbf{I}} \) the part of \( V \) of degree \( \sum_{i \in \mathbf{I}} \delta_i \). We have \( \text{LA}(T_z, \Lambda^k) \cong \langle \Lambda^k(\mathcal{L}_z) \rangle_{[1, z]} \). This isomorphism takes the complex \( 5 \) to

\[ \cdots \to \text{LA}(\mathcal{L}_z, \Lambda^4) \xrightarrow{\text{Alt}_3 \circ (\mu \otimes \text{id} \otimes \text{id})} \text{LA}(\mathcal{L}_z, \Lambda^3) \xrightarrow{\text{Alt}_2 \circ (\mu \otimes \text{id} \otimes \text{id})} \text{LA}(\mathcal{L}_z, \Lambda^2) \to 0, \]

where \( \mu_{\mathcal{L}_z} \) is the Lie bracket of \( \mathcal{L}_z \).

Let \( \text{Part}_k(\mathbf{I}) \) be the set of \( k \)-partitions of a set \( \mathbf{I} \), i.e., of the \( k \)-tuples \( (I_1, \ldots, I_k) \) with \( \bigcup_{i=1}^k I_i = I \). The group \( S_k \) acts on \( \text{Part}_k(\mathbf{I}) \), and we have a decomposition

\[ \langle \Lambda^k(\mathcal{L}_z) \rangle_{[1, z]} = \bigoplus_{(I_1, \ldots, I_k) \in \text{Part}_k(\mathbf{I})} \langle \Lambda^k(\mathcal{L}_z) \rangle_{[1, z], \Lambda^z(I_1, \ldots, I_k),} \]

where the summand is the space of antisymmetric tensors in \( \bigotimes_{i \in \mathbf{I}} (\mathcal{L}_z)_{I_i(1)} \otimes \cdots \otimes (\mathcal{L}_z)_{I_i(k)}. \)

We have a bijection \( \{ (I'_1, (I_2, \ldots, I_k)) \mid I'_1 \subset [2, z], (I'_2, \ldots, I_k) \in \text{Part}_{k-1}([2, z] - I'_1) / S_{k-1} \} \to \text{Part}_k(\mathbf{I}) \)

taking \( (I'_1, (I_2, \ldots, I_k)) \) to \( (I'_1 \cup \{1\}, (I_2, \ldots, I_k)) \). The inverse bijection takes \( (I_1, \ldots, I_k) \) to \( (I_1 - \{1\}, (I_1, \ldots, I_{i-1}, I_{i+1}, \ldots, I_k)) \), where \( i \in [1, k] \) is the index such that \( 1 \in I_i \).

For \( (I'_1, (I_2, \ldots, I_k)) \) in the first set, we have an isomorphism

\[ \langle \Lambda^k(\mathcal{L}_z) \rangle_{[(I'_1 \cup \{1\}), I_2, \ldots, I_k]} \cong \langle \mathcal{L}_z \rangle_{I'_1 \cup \{1\}} \otimes \langle \Lambda^{k-1}(\mathcal{L}_z) \rangle_{[I_2, \ldots, I_k]} \]

(where inverse is given by \( \text{Alt}_k \), or, up to a factor, by the sum of all cyclic permutations if \( k \) is odd, and their alternating sum if \( k \) is even), which gives rise to an isomorphism

\[ \langle \Lambda^k(\mathcal{L}_z) \rangle_{[1, z]} \cong \bigoplus_{(I'_1, (I_2, \ldots, I_k))} \langle \mathcal{L}_z \rangle_{I'_1 \cup \{1\}} \otimes \langle \Lambda^{k-1}(\mathcal{L}_z) \rangle_{[I_2, \ldots, I_k]} \]

We have a complex

\[ \cdots \to \langle \mathcal{L}_z \otimes \Lambda^2(\mathcal{L}_z) \rangle_{[1, z]} \to \langle \mathcal{L}_z \otimes \mathcal{L}_z \rangle_{[1, z]} \to \langle \mathcal{L}_z \rangle_{[1, z]} \to 0, \]

where the differential \( \langle \mathcal{L}_z \otimes \Lambda^k(\mathcal{L}_z) \rangle_{[1, z]} \to \langle \mathcal{L}_z \otimes \Lambda^{k-1}(\mathcal{L}_z) \rangle_{[1, z]} \) is induced by \( x_0 \otimes (x_1 \wedge \ldots \wedge x_k) \mapsto \sum_{i=1}^k (-1)^{i+1} [x_0, x_i] \otimes (x_1 \wedge \ldots \wedge \hat{x}_i \ldots \wedge x_k) + \sum_{1 \leq i < j \leq k} (-1)^{i+j} x_0 \otimes (x_1 \wedge \ldots \wedge [x_i, x_j] \wedge \ldots \wedge x_k) \). If \( I, J \subset [1, z] \) are disjoint, we have \( \langle \mathcal{L}_z \rangle_I, \langle \mathcal{L}_z \rangle_J \subset \langle \mathcal{L}_z \rangle_{I \cup J} \), which implies that if

\[ C_k := \bigoplus_{(I_1, (I_2, \ldots, I_k))} \langle \mathcal{L}_z \rangle_{I_1 \cup \{1\}} \otimes \langle \Lambda^{k-1}(\mathcal{L}_z) \rangle_{[I_2, \ldots, I_k]}, \]

\[ 4 \text{We set } [p, q] := \{p, p+1, \ldots, q\}. \]
then

\[ \ldots \to C_2 \to C_1 \to 0 \]

is a subcomplex of (8), isomorphic to (3).

For \( I' \subset [2, z] \), we have an isomorphism \((A_z)_{I'} \to (L_z)_{I' \cup \{1\}}\), given by \( x_1 \ldots x_i \mapsto [[x_1, x_{i_1}], x_{i_2}, \ldots, x_{i_i}]\); the inverse isomorphism is the restriction of the map \((A_z)_{I' \cup \{1\}} \to (A_z)_{I'}\) taking a monomial not starting with \( x_1 \) to 0, and a monomial starting with \( x_1 \) to the same monomial with the \( x_1 \) removed (see [3]).

The compatibility of these isomorphisms with the Lie bracket can be described as follows: for \( I', I \subset [2, z] \) disjoint, we have a commutative diagram

\[
\begin{array}{ccc}
(A_z)_{I'} \otimes (L_z)_{I} & \to & (A_z) \\
\downarrow & & \downarrow \\
(L_z)_{I' \cup \{1\}} \otimes (L_z)_{I} & \to & (L_z)_{I' \cup \{1\}},
\end{array}
\]

where the upper horizontal map is induced by the product in \( A_z \) (\( L_z \) being viewed as a subspace of \( A_z \)) and the lower horizontal map is induced by the Lie bracket of \( L_z \).

We have a complex

\[
\ldots \to (A_z \otimes \Lambda^2(L_z))[2, z] \to (A_z \otimes L_z)[2, z] \to (A_z)[2, z] \to 0,
\]

where the map \((A_z \otimes \Lambda^k(L_z))[2, z] \to (A_z \otimes \Lambda^{k-1}(L_z))[2, z]\) is induced by \( x_0 \otimes (x_1 \wedge \ldots \wedge x_k) \mapsto \sum_{i=1}^k (-1)^{i+1} x_0 \otimes x_1 \wedge \ldots \wedge x_i \wedge \ldots \wedge x_k + \sum_{1 \leq i < j \leq k} (-1)^{i+j} x_0 \otimes x_1 \wedge \ldots \wedge x_i \wedge x_j \wedge \ldots \wedge x_k.\) The isomorphisms \((L_z)_{I' \cup \{1\}} \simeq (A_z)_{I'\cup\{1\}}\) induce isomorphisms \(C_k \simeq \bigoplus_{(I'\cup\{1\},[i_2 \ldots i_k])} (A_z)_{I'} \otimes (L_z)^{(k-1)}_{I_1} = (A_z \otimes \Lambda^{k-1}(L_z))[2, z]\), which are compatible with the differentials. Hence the complex (3) is isomorphic to \( \ldots \to C_2 \to C_1 \to C_0 \to 0. \)

The complex (3) is the degree \( \delta_2 + \ldots + \delta_k \) part of the complex

\[
\ldots \to A_z \otimes \Lambda^2(L_z) \to A_z \otimes L_z \to A_z \to 0,
\]

where the differentials are defined by the same formulas.

Define a complete increasing filtration on (3) by \( \text{Fil}^p(A_z \otimes \Lambda^k(L_z)) = (A_z)_{\leq n-k} \otimes \Lambda^k(L_z)\), where \((A_z)_{\leq n}\) is the part of degree \( \leq n \) of \( A_z \simeq U(L_z) \) (i.e., the span of products of \( \leq n \) elements of \( L_z \)). The associated graded complex is the sum over \( n \geq 0 \) of complexes \( \ldots \to 0 \to \Lambda^n(L_z) \to \ldots \to \Lambda^{n-1}(L_z) \otimes L_z \to \Lambda^n(L_z) \to 0\), which add up to the Koszul complex

\[
\ldots \to S(L_z) \otimes \Lambda^2(L_z) \to S(L_z) \otimes L_z \to S(L_z) \to 0,
\]

where the differential \( S(L_z) \otimes \Lambda^k(L_z) \to S(L_z) \otimes \Lambda^{k-1}(L_z) = f \otimes (x_1 \wedge \ldots \wedge x_k) \mapsto \sum_{i=1}^k (-1)^{i+1} f x_i \otimes (x_1 \wedge \ldots \wedge \hat{x}_i \wedge \ldots \wedge x_k)\).

Now if \( V \) is a vector space, then the Koszul complex

\[
C(V) := (\ldots \to S(V) \otimes \Lambda^2(V) \to S(V) \otimes V \to S(V) \to 0)
\]

is a sum of complexes, indexed by \( \mathbb{N} \) (this index corresponds to \( p + q \) in \( S^p(V) \otimes \Lambda^q(V) \)). It is well known that the homology of this complex is concentrated in homological degree 0 and in degree 0, where it is equal to \( k \). Recall a proof. One checks this directly when \( V \) is one-dimensional; we have isomorphisms \( C(V \oplus W) \simeq C(V) \otimes C(W) \) of \( \mathbb{N} \)-graded complexes, which implies the statement when \( V \) is finite dimensional. It follows that the Koszul complex in \( \text{Sch} \) given by \( \ldots \to S \otimes \Lambda^2 \to S \otimes \text{id} \to S \otimes 0 \) has its homology concentrated in homological degree 0 and degree 0, where it equals 1. This implies the statement in general.
It follows that the homology of (9) is concentrated in degree 0, where it is equal to $k$; a nontrivial homology class is that of $1 \in A_z$. It follows that the degree $\delta_0 + \ldots + \delta_z$ part of this complex is acyclic if $z \geq 2$, i.e., (3) is acyclic if $z \geq 2$. The computation of the homology of (9) is straightforward when $z = 1$. \hfill \Box

This ends the proof of Theorem 5.1. \hfill \Box

6. Comparison of cohomology groups

Theorem 4.2 means that for any $p \geq 0$ and $q > 0$, the canonical map $H^p_{QLBA}(\text{id}, \Lambda^0) \rightarrow H^p_{QLBA}(\text{id}, \Lambda^0)$ is an isomorphism.

Recall that $H^*(QLBA(\text{id}, \Lambda^0)) = H^*(\Lambda^0_{QLBA})$, where $\Lambda^0_{QLBA} = ((Q)LBA(\Lambda^*, \Lambda^0), [\mu, -])$. If $I$ is a prop ideal in QLBA, we also set $C^i_I := I(\Lambda^*, \Lambda^q)$; this is a subcomplex of $C^*_{QLBA}$. We then have an exact sequence of complexes $0 \rightarrow C^*_{QLBA} \rightarrow C^*_{QLBA} \rightarrow 0$, inducing a long exact sequence in cohomology, so Theorem 4.2 will be proved if we show that $(C^*_{QLBA}, [\mu, -])$ is acyclic.

Observe now that we have a decreasing sequence of complexes $C^*_{QLBA} \supset C^*_{QLBA} \supset \ldots$. All these complexes are graded by $d_{\delta z}$ and in each fixed degree, the decreasing filtration is complete (i.e., for any fixed $p, d, C^p_{QLBA}, [d] = 0$ for $n$ large enough, where $[d]$ means the part with $d_{\delta z}$ equal to $d$). It then suffices to prove that the associated graded complex $(\bigoplus_{i=0} C^i_{QLBA})/C^i_{QLBA+1}$, induced differential) is acyclic. This complex coincides with $(\bigoplus_{i>0} LBA_x^i(\Lambda^*, \Lambda^0), [\tilde{\mu}, -])$, where the exponent $(i)$ means the homogeneous part with $d_{\tilde{\delta z}}$ equal to $i$, and $d_{\tilde{\delta z}}$ is the degree on $LBA_x$ such that $(\tilde{\mu}, \tilde{\delta}, \tilde{\varphi}) \mapsto (0, 0, 1)$.

In order to prove that the latter complex is acyclic, we will prove more generally:

**Theorem 6.1.** Let $C, D$ be homogeneous Schur functors of positive degrees; let $\kappa \in LCA(C, D)$. Let $LBA_x(X, Y) := \text{Coker}(LBA(D \otimes X, Y) \rightarrow LBA(C \otimes X, Y))$. Then for any $q \geq 0$, the complex $(LBA_x(\Lambda^p, \Lambda^q), [\mu, -])_{p \geq 0}$ is acyclic.

**Proof.** Let us make this complex explicit. For $Z \in \text{Irr(Sch)}$, define $\mu_Z \in LA(\text{id} \otimes Z, Z)$ and $\tilde{\mu}_Z \in LA(Z \otimes \text{id}, Z)$ as follows: $\mu_p \in LA(\text{id} \otimes T_p, T_p)$ is the universal version of $x \otimes x_1 \otimes \ldots \otimes x_p \mapsto \sum_{i=1}^p x_1 \otimes \ldots \otimes [x, x_i] \otimes \ldots \otimes x_p$; as it is $G_p$-equivariant, it decomposes under $LA(\text{id} \otimes T_p, T_p) \simeq \bigoplus_{p, W, |Z|=|W|=p} LA(\text{id} \otimes Z, W) \otimes \text{Vect}(\pi_Z, \pi_W)$ as $\bigoplus_Z \mu_Z \otimes \text{id}_{\pi_Z}$. We then set $\tilde{\mu}_Z := -\mu_Z \circ \beta_{Z, \text{id}} : Z \otimes \text{id} \rightarrow \text{id} \otimes Z$ is the braiding morphism.

Then $[\mu, -] : LBA(C \otimes \Lambda^p, \Lambda^q) \rightarrow LBA(C \otimes \Lambda^{p+1}, \Lambda^q)$ is the composed map $LBA(C \otimes \Lambda^p, \Lambda^q) \rightarrow LBA(C \otimes \Lambda^p \otimes \text{id}, \Lambda^q) \rightarrow LBA(C \otimes \Lambda^{p+1}, \Lambda^q)$, where the first map is $x \mapsto x \circ (\text{id}_C \otimes \tilde{\mu}_{\Lambda^p})$ and the second map is $y \mapsto y \circ \text{Alt}_{p+1}$. We have a similar differential, with $C$ replaced by $D$, and $\kappa$ induces a commutative diagram

$$
\begin{align*}
\text{LBA}(D \otimes \Lambda^p, \Lambda^q) & \rightarrow \text{LBA}(D \otimes \Lambda^p \otimes \text{id}, \Lambda^q) \rightarrow \text{LBA}(D \otimes \Lambda^{p+1}, \Lambda^q) \\
\downarrow & \downarrow \\
\text{LBA}(C \otimes \Lambda^p, \Lambda^q) & \rightarrow \text{LBA}(C \otimes \Lambda^p \otimes \text{id}, \Lambda^q) \rightarrow \text{LBA}(C \otimes \Lambda^{p+1}, \Lambda^q).
\end{align*}
$$

The cokernel of this diagram is $LBA_x(\Lambda^p, \Lambda^q) \rightarrow LBA_x(\Lambda^p \otimes \text{id}, \Lambda^q) \rightarrow LBA_x(\Lambda^{p+1}, \Lambda^q)$ and the composed map is the differential of our complex.
Recall that for $X_i, Y \in \text{Ob}(\text{Sch})$, $i = 1, \ldots, n$, we have an isomorphism $LBA(X_1 \otimes \cdots \otimes X_n, Y) \simeq \bigoplus_{Z_1, \ldots, Z_n \in \text{Irr}(\text{Sch})} \text{LCA}(X_1, Z_1) \otimes \cdots \otimes \text{LCA}(X_n, Z_n) \otimes \text{LA}(Z_1 \otimes \cdots \otimes Z_n, Y) = \bigoplus_{Z_1, \ldots, Z_n} LBA(X_1 \otimes \cdots \otimes X_n, Y)_{Z_1, \ldots, Z_n}$. The inverse isomorphism is the direct sum of the maps $c_1 \otimes \cdots \otimes c_n \otimes a \mapsto a \circ (c_1 \otimes \cdots \otimes c_n)$. If $X_i$ is homogeneous of positive degree, $\text{LCA}(X_i, 1) = 0$, so the above sum may be restricted by the condition $|Z_i| > 0$.

We now define a complex $0 \to C^0 \xrightarrow{d^0} C^1 \to \cdots$ as follows. The analogue of the above complex $[\mu, -] : LBA(C \otimes \Lambda^p, \Lambda^q) \to LBA(C \otimes \Lambda^{p+1}, \Lambda^q)$ (with $C$ replaced by $Z$) admits a subcomplex, namely $C^p_{Z,q} := \bigoplus_{Z \in \text{Irr}(\text{Sch}), |Z| > 0} LBA(Z \otimes \Lambda^p, \Lambda^q)_{Z,q}$,

$$d^{p,p+1}_{Z,q} : C^p_{Z,q} \to C^{p+1}_{Z,q}$$

is then the restriction of the differential $[\mu, -]$. We then have an isomorphism between the complexes $(LBA(C \otimes \Lambda^p, \Lambda^q), [\mu, -])_{p \geq 0}$ and $\bigoplus_{Z \in \text{Irr}(\text{Sch}), |Z| > 0} LCA(C, Z) \otimes (C^p_{Z,q}, d^{p,p+1}_{Z,q})_{p \geq 0}$. We have a similar isomorphism replacing $C$ by $D$, and these isomorphisms are compatible with the morphisms of complexes induced by $\kappa$. Taking cohomology groups, we get an isomorphism of complexes

$$(LBA_n(\Lambda^p, \Lambda^q), [\mu, -])_{p \geq 0} \simeq \bigoplus_{Z \in \text{Irr}(\text{Sch}), |Z| > 0} \text{Coker} (LCA(D, Z) \to LCA(C, Z)) \otimes (C^p_{Z,q}, d^{p,p+1}_{Z,q})_{p \geq 0}.$$

We now prove the acyclicity of $(C^p_{Z,q}, d^{p,p+1}_{Z,q})_{p \geq 0}$, for any $q \geq 0$ and any $Z \in \text{Irr}(\text{Sch}), |Z| > 0$. To lighten notation, we will denote it by $(C^p, d^{p,p+1})_{p \geq 0}$. We reexpress this complex as follows. View $C^p$ as the antisymmetric part under the action of $\mathfrak{S}_p$ of $\tilde{C}^p := \bigoplus_{Z_1, \ldots, Z_p \in \text{Irr}(\text{Sch})} LBA(Z \otimes \text{id}^{\otimes p}, \Lambda^q)_{Z_1, \ldots, Z_p} \subset LBA(Z \otimes \text{id}^{\otimes p}, \Lambda^q)$ (we may restrict this sum by the condition $|Z_i| > 0$). Define

$$\tilde{d}^{p,p+1} : LBA(Z \otimes \text{id}^{\otimes p}, \Lambda^q) \to LBA(Z \otimes \text{id}^{\otimes p+1}, \Lambda^q)$$

by $\tilde{d}^{p,p+1}(x) := x \circ (\text{id}_Z \otimes \mu \circ \text{id}_{\otimes p+1}^{-1})(-1)^{i+j} \beta_{ij} + \mu_{\text{id}, \otimes} \circ (\text{id}_Z \otimes x) \circ (-1)^{i+j} \beta_{ij}$, where $\beta_{ij}$ is the automorphism of $Z \otimes \text{id}^{\otimes p+1}$, which is the universal version of $z \otimes x_1 \otimes \cdots \otimes x_{p+1} \mapsto z \otimes x_1 \otimes x_{p+1} \mapsto \cdots \mapsto x_{p+1}$, for any $Z \otimes \text{id}^{\otimes p+1} \to \text{id} \otimes Z \otimes \text{id}^{\otimes p}$ is the universal version of $z \otimes x_1 \otimes \cdots \otimes x_{p+1} \mapsto x_1 \otimes z \otimes x_1 \otimes \cdots \otimes x_{p+1}$. Then $\tilde{d}^{p,p+1}$ restricts to $d^{p,p+1} : C^p \to C^{p+1}$.

We now introduce a filtration on $C^p$. Let $(\tilde{C}^p)^{\leq p'} \subset \tilde{C}^p$ be the sum of all terms where $\text{card}\{i | Z_i = \text{id}\} \leq p'$. This subspace is invariant under the action of $\mathfrak{S}_p$, so its totally antisymmetric part is a subspace $(\tilde{C}^p)^{\leq p'} \subset C^p$.

**Lemma 6.1.** $d^{p,p+1}((\tilde{C}^p)^{\leq p'}) \subset (C^{p+1})^{\leq p'+1}$.

**Proof.** To prove this, we will prove that $\tilde{d}^{p,p+1}((\tilde{C}^p)^{\leq p'}) \subset (C^{p+1})^{\leq p'+1}$. If $x \in LBA(Z \otimes \text{id}^{\otimes p}, \Lambda^q)_{Z, Z_1, \ldots, Z_p}$, then $\mu_{\text{id}, \otimes} \circ (\text{id}_Z \otimes x) \circ \beta_i$ is clearly in $LBA(Z \otimes \text{id}^{\otimes p+1}, \Lambda^q)_{Z, Z_1, \ldots, Z_{p+1}}$. Hence $\text{card}\{i | Z_i = \text{id}\}$ has been increased by 1. Moreover, for any $W \in \text{Irr}(\text{Sch})$, the image of $\text{LCA}(\text{id}, W) \to LBA(\text{id}^{\otimes 2}, W)$, $c \mapsto c \circ \mu$ lies in

$$\bigoplus_{W_1, W_2 \in \text{Irr}(\text{Sch}), |W_i| > 0, |W_1| + |W_2| = |W| + 1} \text{LBA}(\text{id}^{\otimes 2}, W)_{W_1, W_2}.$$
Lemma 6.2.

Let \( W_1, W_2 \in \text{Irr}(\text{Sch}) \) be such that \(|W_1| > 0, |W_1| + |W_2| = |Z| + 1, \{i|W_i| = 1\}\) is \( \leq 1 \) if \(|Z_1| > 1\) and \( = 2 \) if \(|Z_1| = 1\). So in the summands of \(|\{\}^1, \text{card}\{i|Z_i| = 1\}\) is increased by at most 1.

It follows that the differential \( d_{p'}^{p+1} \) is compatible with the filtration \( (C^p)^{\leq 0} \subset \ldots \subset (C^p)^{\leq p} = C^p \). To prove that it is acyclic, we will prove that the associated graded complex is acyclic. For this, we first determine this associated graded complex.

For \( p' + p'' = p \), let

\[
\tilde{C}'p'' := \bigoplus_{\text{card}_i|Z_i| > 1} \text{LBA}(Z \otimes \text{id}^{\otimes p'}, \Lambda^q)_{Z_i, \ldots, Z_{i'}, \ldots, Z_{i''}, \ldots}.
\]

Let \( C'p'' \) be the antisymmetric part of this space with respect to the action of \( \mathfrak{S}_{p'} \times \mathfrak{S}_{p''} \).

**Lemma 6.2.** \( (C^p)^{\leq p'}/(C^p)^{\leq p' - 1} = C'p'' \), where \( p'' = p - p' \).

**Proof.** We have

\[
(\tilde{C}'p')^{\leq p'}/(\tilde{C}'p)^{\leq p' - 1} = \bigoplus_{\text{card}_i|Z_i| = \text{id} = p'} \text{LBA}(Z \otimes \text{id}^{\otimes p'}, \Lambda^q)_{Z_i, \ldots, Z_p}.
\]

As a \( \mathfrak{S}_p \)-module, the r.h.s. identifies with \( \text{Ind}_{\mathfrak{S}_{p'} \times \mathfrak{S}_{p''}}^{\mathfrak{S}_p} (\tilde{C}'p'' \cdot \sigma) \). \( (C^p)^{\leq p'}/(C^p)^{\leq p' - 1} \) is then the \( \mathfrak{S}_p \)-anti-invariant part of this space, which identifies with the \( \mathfrak{S}_{p'} \times \mathfrak{S}_{p''} \)-anti-invariant part of \( C'p'' \cdot \sigma \), i.e., \( C'p'' \cdot \sigma \). The isomorphism\(^5\)

\[
\left( \bigoplus_{|Z_1, \ldots, Z_p| > 0, \text{card}_i|Z_i| = \text{id} = p'} \text{LBA}(Z \otimes \text{id}^{\otimes p'}, \Lambda^q)_{Z_i, \ldots, Z_p} \right)^{\mathfrak{S}_p^+} \rightarrow \left( \bigoplus_{|Z_1, \ldots, Z_p'| > 1} \text{LBA}(Z \otimes \text{id}^{\otimes p'}, \Lambda^q)_{Z_i, \ldots, Z_p'} \right)^{\mathfrak{S}_{p'} \times \mathfrak{S}_{p''}}
\]

is given by projection on the relevant components, and the inverse isomorphism is given by the action of \((1/p!) \sum_{\sigma \in \mathfrak{S}_p} \epsilon(\sigma)\sigma \) (or \((p'/p'')! / p! \sum_{\sigma \in \mathfrak{S}_{p'} \times \mathfrak{S}_{p''}} \epsilon(\sigma)\sigma \), where \( \mathfrak{S}_{p'} \times \mathfrak{S}_{p''} \) is the set of \( p', p'' \)-shuffle permutations). \( \quad \square \)

\(^5\)For \( M \) a module over \( \prod_i \mathfrak{S}_p \), we denote by \( M^{(\prod_i \mathfrak{S}_p)^-} \) the component of \( M \) of type \( \otimes_i \epsilon_i \), where \( \epsilon_i \) is the signature character of \( \mathfrak{S}_p \).

Define
\[ \tilde{d}^p : \text{LBA}(Z \otimes \id^p \otimes \Lambda^q) \rightarrow \text{LBA}(Z \otimes \id^{p+1} \otimes \Lambda^q) \]
by \( x \mapsto x \circ (\id_{\Lambda^q} \otimes \Lambda^q) \circ \sum_{1 \leq i < j \leq p+1} (-1)^{i+j+1} \beta_{ij} \).

Lemma 6.3. The map \( \tilde{d}^p \) restricts to maps \( \tilde{d}^p \rightarrow \tilde{d}^{p+1} \) and \( d^p \rightarrow d^{p+1} \), and the map \( (Cp)^{\leq p} / (Cp)^{\leq p-1} \rightarrow (Cp+1)^{\leq p+1} / (Cp+1)^{\leq p} \) induced by \( d^{p+1} \) coincides with \( d^{p+1} \), where \( p \leq p' \).

For each \( p'' \), \( (Cp'' \otimes \Lambda'' \otimes \Lambda^q(a)) \) is a complex.

Proof. If \( x \in \text{LBA}(Z \otimes \id^p \otimes \Lambda^q) \), then one checks that both \( x \circ (\id \otimes \id^p) \circ \beta_{ij} \) and \( x \circ (\id \otimes \id^p) \otimes \beta_{ij} \) lie in \( \text{LBA}(Z \otimes \id^{p+1} \otimes \Lambda^q) \), which implies that \( d^{p+1} \) induces a map \( \tilde{d}^p \rightarrow \tilde{d}^{p+1} \). The map \( d^{p+1} \) maps the \( \id^p \otimes \Lambda^q - \)antisymmetric part of \( \text{LBA}(Z \otimes \id^p \otimes \Lambda^q) \) to its analogue with \( p' \) increased by 1, so it restricts to a map \( (Cp)^{\leq p} / (Cp)^{\leq p-1} \rightarrow (Cp+1)^{\leq p+1} / (Cp+1)^{\leq p} \).

Let us now show that the map \( (Cp)^{\leq p} / (Cp)^{\leq p-1} \rightarrow (Cp+1)^{\leq p+1} / (Cp+1)^{\leq p} \) is induced by \( d^{p+1} \).

Let \( Z_1, ..., Z_p \in \text{Irr}(\text{Sch}) \) be such that \( Z_i \) is \( \id \) for \( i \leq p' \) and \( |Z_i| > 1 \) if \( i > p' \). Let \( y \in \text{LCA}(Z \otimes Z_1 \otimes ... \otimes Z_p) \), where \( c_i \in \text{LCA}(\id, Z_i) \) and \( a \in \text{LA}(Z \otimes Z_1 \otimes ... \otimes Z_p, \Lambda^q) \). Let \( x := y \circ (\id \otimes (\sum c_i \in \text{E}_{p'}(c_i \sigma)) \) and \( \tilde{x} := y \circ (\id \otimes (\sum c_i \in \text{E}_{p'}(c_i \sigma)) \).

We now use the fact that if \( c \in \text{LCA}(\id, Z) \), then
\[ c \circ \mu = \mu \circ (\id \otimes c) + \bar{\mu} \circ (c \otimes \id) \]
where \( \beta : Z_{\sigma(1)} \otimes ... \otimes Z_{\sigma(p)} \rightarrow Z_{\sigma(1)} \otimes ... \otimes Z_p \) is the braiding map.

We now use the fact that if \( c \in \text{LCA}(\id, Z) \), then
\[ c \circ \mu = \mu \circ (\id \otimes c) + \bar{\mu} \circ (c \otimes \id) + \kappa(c), \]
where \( \kappa(c) \) is the correction term.

License or copyright restrictions may apply to redistribution; see https://www.ams.org/journal-terms-of-use
Taking isotypic components under the action of $\delta \otimes \text{id}^{p-2}$, we first prove it when $Z = T_p (p > 0)$ and $c = (\delta \otimes \text{id}^{p-2}) \circ \ldots \circ \delta$ (iterating the use of the cocycle identity); as this element generates the $\mathfrak{g}_p$-module $\text{LCA}(\text{id}, T_p)$, this implies the identity when $Z = T_p$. The case of $Z \in \text{Irr} (\text{Sch})$, $|Z| = p$ is derived from there by taking isotypic components under the action of $\mathfrak{g}_p$.

When $|Z_{\sigma (1)}| > 1$, the contribution of $\kappa (c_{\sigma (1)})$ to (11) belongs to $(\tilde{C}^{p+1})^{p'}$. The class of (11) in $(\tilde{C}^{p+1})^{p' +1}/(\tilde{C}^{p+1})^{p'}$ is then the same as that of (13)

$$
\sum_{1 \leq i < j \leq p+1} (-1)^{i+j} \sum_{\sigma \in \mathfrak{g}_p} a \circ (\text{id}_Z \otimes \beta_\sigma) \circ (\text{id}_Z \otimes (\mu_{Z_{\sigma (1)}} \circ (\text{id}_Z \otimes c_{\sigma (1)})))
\otimes c_{\sigma (2)} \otimes \ldots \otimes c_{\sigma (p)} \circ \beta_{ij}
$$

$$+
\sum_{1 \leq i < j \leq p+1} (-1)^{i+j} \sum_{\sigma \in \mathfrak{g}_p} a \circ (\text{id}_Z \otimes \beta_\sigma) \circ (\text{id}_Z \otimes (\tilde{\mu}_{Z_{\sigma (1)}} \circ (c_{\sigma (1)} \otimes \text{id}_Z)))
\otimes c_{\sigma (2)} \otimes \ldots \otimes c_{\sigma (p)} \circ \beta_{ij}
$$

$$+
\sum_{1 \leq i < j \leq p+1} (-1)^{i+j+1} \sum_{\sigma \in \mathfrak{g}_p, \sigma (1) \in [1,p']}(\epsilon (\sigma) a \circ (\text{id}_Z \otimes \beta_\sigma) \circ (\text{id}_Z \otimes (\nu_{Z_{\sigma (1)}} \circ (\text{id}_Z \otimes c_{\sigma (1)})))
\otimes \ldots \otimes c_{\sigma (p)} \circ \beta_{ij}
$$

The first line may be rewritten as follows. Let $\alpha_j \in \mathfrak{g}_p$ be the cycle $\alpha_j (1) = 2, \ldots, \alpha_j (j - 2) = j - 1, \alpha_j (j - 1) = 1, \alpha_j (j) = j, \ldots, \alpha_j (p) = p$. In terms of $\tau := \sigma \circ \alpha_j$, this line can be expressed as

$$
\sum_{j \in [1,p+1]} \sum_{i < j} \sum_{\tau \in \mathfrak{g}_p} (-1)^i \epsilon (\tau) a \circ (\text{id}_Z \otimes \beta_\tau) \circ (\text{id}_Z \otimes c_{\tau (1)} \otimes \ldots \otimes (\mu_{Z_{\tau (j-1)}} \circ (\text{id}_Z \otimes c_{\tau (j-1)}) \circ \ldots \otimes c_{\tau (p)}) \circ \gamma_{ij},
$$

where $\gamma_{ij} \in \text{Aut} (Z \otimes \text{id}^{\otimes p})$ is the categorical version of $z \otimes x_1 \otimes \ldots \otimes x_{p+1} \mapsto z \otimes x_1 \otimes \ldots \otimes x_i \otimes \ldots \otimes x_{j-1} \otimes x_i \otimes \ldots \otimes x_{j+1} \otimes \ldots \otimes x_{p+1}$. In the same way, one shows that the second line has the same expression, with the condition $i < j$ replaced by $i > j$ and $\gamma_{ij}$ the categorical version of $z \otimes x_1 \otimes \ldots \otimes x_{p+1} \mapsto z \otimes x_1 \otimes \ldots \otimes x_{j-1} \otimes x_i \otimes \ldots \otimes x_j \otimes x_{j+1} \otimes \ldots \otimes x_{p+1}$.

Adding up these lines, and using the identity

$$
\mu_{W} \circ (\text{id}_Z \otimes a) = \sum_{a=1}^{k} a \circ (\text{id}_{W_1} \otimes \ldots \otimes \mu_{W_a} \otimes \ldots \otimes \text{id}_{W_k}) \circ \beta_a,
$$

in $\text{LA} (\text{id} \otimes W_1 \otimes \ldots \otimes W_k, W)$, where $a \in \text{LA} (W_1 \otimes \ldots \otimes W_k, W)$ and $\beta_a$ is the braiding $\text{id} \otimes W_1 \otimes \ldots \otimes W_k \rightarrow W_1 \otimes \ldots \otimes W_{a-1} \otimes \text{id} \otimes W_a \otimes \ldots \otimes W_k$, we express the contribution of (11) as (last line of (13)) $+ \mu_{\lambda \sigma} \circ (\text{id}_Z \otimes \mu_{\lambda \sigma}) \circ (\text{id}_Z \otimes \mu_{\lambda \sigma} \otimes \mu_{\lambda \sigma} \otimes \ldots \otimes \mu_{\lambda \sigma}) \circ \beta_{ij}$. The class of $\text{id}_{p+1}^{\otimes p}$ in $(\tilde{C}^{p+1})^{p' +1}/(\tilde{C}^{p+1})^{p'}$ is therefore the same as that of (last line of (13)) $+ \mu_{\lambda \sigma} \circ (\text{id}_Z \otimes \mu_{\lambda \sigma} \otimes \mu_{\lambda \sigma} \otimes \ldots \otimes \mu_{\lambda \sigma}) \circ (\text{id}_Z \otimes \mu_{\lambda \sigma} \otimes \mu_{\lambda \sigma} \otimes \ldots \otimes \mu_{\lambda \sigma}) \circ \beta_{ij}$. To evaluate its image in $C(p' +1)^{p'}$, we apply the projection of $\bigoplus_{Z_1, \ldots, Z_{p+1}} \text{LBA} (Z \otimes \text{id}^{\otimes p+1}, W) Z, Z, \ldots, Z_{p+1}$ on the sum of the components with $Z_1 = \ldots = Z_{p+1} = \text{id}$, $|Z_{p+1}|, \ldots, |Z_{p+1}| > 1$ along the other components.
We have \( \hat{x} \circ (\mu_Z \otimes \text{id}_\otimes) \circ \hat{\beta}_i = \sum_{\sigma \in \mathfrak{S}_\sigma} \epsilon(\sigma) a \circ (\text{id}_Z \otimes \beta_\sigma) \circ (\mu_Z \otimes c_{\sigma(1)} \otimes \ldots \otimes c_{\sigma(p)}) \circ \hat{\beta}_i \), and the summand corresponding to \( \sigma \) belongs to

\[
\text{LBA}(Z \otimes \text{id}_\otimes \otimes \Lambda^q) Z, Z_{\sigma(1)}, \ldots, Z_{\sigma(n)}, \text{id}, Z_{\sigma(n+1)}, \ldots, Z_{\sigma(p)};
\]

the projection is the identity on the terms such that \( i \in [1, p'+1] \) and \( \sigma \in \mathfrak{S}_\sigma \times \mathfrak{S}_\sigma \) and zero on the other ones. So the projection of \( \hat{x} \circ (\mu_Z \otimes \text{id}_\otimes) \circ (\sum_i^{n+1} \beta_i) \) is \( x \circ (\mu_Z \otimes \text{id}_\otimes) \circ (\sum_i^{n+1} (-1)^{i+1} \beta_i) \).

Let us compute the projection of the last line of (13). The term in this line corresponding to \( i, j, \sigma \) belongs to

\[
\text{LBA}(Z \otimes \text{id}_\otimes \otimes \Lambda^q) Z, Z_{\sigma(1)}, \ldots, Z_{\sigma(n+1)}, \text{id}, Z_{\sigma(n+1)}, \ldots, Z_{\sigma(p)};
\]

the projection is therefore

\[
\text{id} \otimes \text{id} \otimes \Lambda^q.
\]

We now prove that for each \( p'' \geq 0 \), the complex \( (\text{C}_{p'}, \text{d}_{p', p'' + 1}) \) is acyclic. For \( Z'' = (Z'_1, \ldots, Z'_{p''}) \in \text{Irr}(\text{Sch}) \), let

\[
\text{d}^p_{Z''} : \text{LA}(Z \otimes \text{id}_\otimes, \Lambda^q) \to \text{LA}(Z \otimes \text{id}_\otimes, \Lambda^q)
\]

be defined by the same formula as \( \text{d}^p_{p', p'' + 1} \), replacing \( \text{id}_{\otimes_{\sigma}} \) by \( \text{id}_{\otimes_{\sigma}} \) and \( \text{id}_\otimes \) by \( \text{id}_\otimes \). Let \( C^p_{Z''} \) be the antisymmetric part of \( \text{LA}(Z \otimes \text{id}_\otimes \otimes \otimes, \Lambda^q) \) (with respect to the action of \( \mathfrak{S}_\sigma \)). Then \( \text{d}^p_{Z''} \) restricts to a differential \( \text{d}^p_{Z''} : C^p_{Z''} \to C^p_{Z''} \); moreover, we have an isomorphism between \( (\text{C}_{p'} \otimes \otimes, \text{d}_{p', p'' + 1} \vert_{p''}) \) and the antisymmetric part (with respect to the action of \( \mathfrak{S}_\sigma \)) of

\[
\bigoplus_{Z''_{p''}, Z''_{p''} \in \text{Irr}(\text{Sch}), \mid \mid Z''_{p''} \mid \neq 0, 1} \text{LA}(\text{id}, Z''_{p''}) \otimes (C^p_{Z''}, \text{d}^p_{Z''} \vert_{p''} \geq 0, p'' \geq 0).
\]

Since the differential of this complex is \( \mathfrak{S}_\sigma \)-equivariant, it suffices to prove that each complex \( (C^p_{Z''}, \text{d}^p_{Z''} \vert_{p''} \geq 0, p'' \geq 0) \) is acyclic.

Let \( z := |Z|, N := \sum_i |Z_i| \); let

\[
\text{d}^p_{z, n, q} : \text{LA}(\text{id}_\otimes \otimes \text{id}_\otimes \otimes \otimes, \text{id}_\otimes) \to \text{LA}(\text{id}_\otimes \otimes \text{id}_\otimes \otimes \otimes, \text{id}_\otimes)
\]

be defined by the same formula as \( \text{d}^p_{z, n, q} \), replacing \( \otimes_i Z_i \) by \( \text{id}_\otimes \) and \( \mu_Z \) by \( \mu_{\text{id}_\otimes} \). Let \( C^p_{z, n, q} \) be the antisymmetric part of \( \text{LA}(\text{id}_\otimes \otimes \text{id}_\otimes \otimes \otimes, \text{id}_\otimes) \) (with respect to the action of \( \mathfrak{S}_\sigma \)). Then \( \text{d}^p_{z, n, q} \) restricts to a differential \( \text{d}^p_{z, n, q} : C^p_{z, n, q} \to C^p_{z, n, q} \). The complex \( (C^p_{z, n, q}, \text{d}^p_{z, n, q} \vert_{p''} \geq 0) \) is equipped with
a natural action of $\mathfrak{S}_z \times \prod_i \mathfrak{S}_|z_i| \times \mathfrak{S}_q$, and $(C^p_{z,N,q}, d^p_{z,N,q}+1)$ is an isotypic component of this action. It suffices therefore to prove that $(C^p_{z,N,q}, d^p_{z,N,q}+1)_{p \geq 0}$ is acyclic.

In what follows, we denote by $\mathcal{L}(u_1, \ldots, u_s)$ (resp., $\mathcal{A}(u_1, \ldots, u_s)$) the free Lie (resp., associative) algebra generated by $u_1, \ldots, u_s$. These spaces are graded by $\bigoplus_{i \in [1,p]} \mathbb{N} \delta_i$ and for $S \subset [1,p]$, we denote by $\mathcal{L}(u_1, \ldots, u_s)_S, \mathcal{A}(u_1, \ldots, u_s)_S$ the subspaces of degree $\bigoplus_{i \in S} \delta_i$. In the case of two sets of generating variables $(u_1, \ldots, u_s)$ and $(v_1, \ldots, v_t)$, the spaces are graded by $\bigoplus_{i \in [1,s]} \bigoplus_{j \in [1,t]} \mathbb{N} \delta_i$ and we use the same notation for homogeneous subspaces.

**Lemma 6.4.** We have an isomorphism of complexes

\[
C^p_{z,N,q} \simeq \bigoplus_{\{\alpha = i: |I_\alpha| = 1, s\}} \bigotimes_{a=1}^{q} C^p_{|I_{\alpha}|, |I_{\alpha}|, 1}.
\]

**Proof.** Identify $C^p_{z,N,q}$ with $(\mathcal{L}(a_1, \ldots, a_{z+N}, x_1, \ldots, x_{p'})^{\otimes q})_{\otimes p'}^{\otimes z}\otimes (\mathcal{L}(a_1, \ldots, a_{z+N}, x_1, \ldots, x_{p'})^{\otimes q})^{\otimes p'}_{\otimes z'}$, which is the part of the $q$-th tensor power of $\mathcal{L}(a_1, \ldots, x_{p'})$, multilinear in $a_1, \ldots, a_{z+N}, x_1, \ldots, x_{p'}$, and antisymmetric in $x_{1}, \ldots, x_{p'}$ ($a_1, \ldots, a_z$ correspond to the $z$ factors of $\text{id}^{\otimes z}$, $a_{z+1}, \ldots, a_{z+N}$ to the $N$ factors of $\text{id}^{\otimes N}$, and $x_1, \ldots, x_{p'}$ to the $p'$ factors of $\text{id}^{\otimes p'}$).

The differential $d^p_{z,N,q}+1$ can then be expressed as

\[
F(a_1, \ldots, a_{z+N}, x_1, \ldots, x_{p'}) \mapsto \sum_{1 \leq i < j \leq p'+1} (-1)^{i+j+1} F(a_1, \ldots, a_{z+N}, [x_i, x_j], x_1, \ldots, \hat{x}_i, \ldots, \hat{x}_j, \ldots, x_{p'+1})
\]

\[
+ \sum_{1 \leq i \leq p'+1} \sum_{1 \leq i \leq p'} (-1)^{i+j+1} F(a_1, \ldots, [a_i, a_{z'}], \ldots, a_{z+N}, x_1, \ldots, \hat{x}_i, \ldots, x_{p'+1}).
\]

On the other hand, we have an isomorphism

\[
\text{LA}(\text{id}^{\otimes N}, \text{id}^{\otimes q}) \simeq \bigoplus_{I_1 \cup \ldots \cup I_q = [1,N]} \bigotimes_{a=1}^{q} \text{LA}(\text{id}^{\otimes |I_a|}, \text{id}),
\]

with its inverse given by the sum of the maps $a_1 \otimes \ldots \otimes a_q \mapsto (a_1 \otimes \ldots \otimes a_q) \circ \beta_{I_1, \ldots, I_q}$, where $\beta_{I_1, \ldots, I_q} : \text{id}^{\otimes N} \to \bigotimes_{a=1}^{q} \text{id}^{\otimes |I_a|}$ is the braiding induced by the maps $[1, N] \to \prod_{a=1}^{q} [1, |I_a|]$, taking $I_a$ to $[1, |I_a|] \times \{\alpha\}$ by preserving the order. Analyzing the action of $\mathfrak{S}_N$ on the set of $q$-compositions of $[1, N]$, we derive an isomorphism $\text{LA}(\Lambda^N, \text{id}^{\otimes q}) \simeq \bigoplus_{N_1+\ldots+N_q=N} \bigotimes_{a=1}^{q} \text{LA}(\Lambda^{N_a}, \text{id})$, with inverse given by the direct sum of the maps $a_1 \otimes \ldots \otimes a_q \mapsto (a_1 \otimes \ldots \otimes a_q) \circ \beta_{N_1, \ldots, N_q}$, where

---

6For $A_1, \ldots, A_s \subset \mathbb{N}$, we set $\coprod_i A_i := \bigcup_{i \in \{1, \ldots, s\}} A_i \times \{i\} \subset \mathbb{N} \times \{1, \ldots, s\}$. 

License or copyright restrictions may apply to redistribution; see https://www.ams.org/journal-terms-of-use
\[ \beta_{N_1, \ldots, N_q} : \Lambda^N \to \Lambda^{N_1} \otimes \ldots \otimes \Lambda^{N_q} \] is the composite Schur morphism \( \Lambda^N \to \text{id} \otimes^N \simeq \bigotimes_{\alpha} \text{id}^{\otimes N_{\alpha}} \to \bigotimes_{\alpha} \Lambda^{N_{\alpha}} \). One proves similarly that we have an isomorphism

\[ \text{LA}(\text{id} \otimes^z \Lambda^{p'} \otimes \text{id}^{\otimes N_q} : \text{id}^{\otimes q}) \simeq \]

\[ \bigoplus_{\cup_\alpha I_\alpha = [1, z], \cup_\alpha J_\alpha = z + [1, N], \sum_\alpha p_\alpha = p'} \boxtimes \text{LA}(\text{id}^{\otimes |J_\alpha|} \otimes \Lambda^{p_\alpha} \otimes \text{id}^{\otimes |J_\alpha|}, \text{id}), \]

with its inverse induced by the direct sum of the maps \( \bigotimes_{\alpha} \alpha_a \mapsto (\bigotimes_{\alpha} \alpha_a) \circ \beta(I_a), (J_a), (p_\alpha) \), where \( \beta(I_\alpha), (J_\alpha), (p_\alpha) : \text{id}^{\otimes z} \otimes \Lambda^{p'} \otimes \text{id}^{\otimes N_q} \to \bigotimes_{\alpha} (\text{id}^{\otimes |J_\alpha|} \otimes \Lambda^{p_\alpha} \otimes \text{id}^{\otimes |J_\alpha|}) \) is constructed from the above Schur morphisms. It follows that we have the isomorphism \[ \text{identifies with the map} \]

\[ \bigotimes_{\alpha} \mathcal{L}(a_1, \ldots, x_{p'})^{\sigma_\alpha} (I_\alpha, \cup_\alpha J_\alpha) \coprod \ldots \coprod \coprod (p_1 + \ldots + p_{n-1} + [1, p_n]), \]

\[ \to \bigotimes_{\alpha} \mathcal{L}(a_1, \ldots, x_{p'}) (I_\alpha, \cup_\alpha J_\alpha) \coprod \ldots \coprod \coprod (p_1 + \ldots + p_{n-1} + [1, p_n]), \]

(\where the second map is the projection along all other components) restricts to

\[ \bigotimes_{\alpha} \mathcal{L}(a_1, \ldots, x_{p'})^{\sigma_\alpha} (I_\alpha, \cup_\alpha J_\alpha) \coprod \ldots \coprod \coprod (p_1 + \ldots + p_{n-1} + [1, p_n]), \]

\[ \to \bigotimes_{\alpha} \mathcal{L}(a_1, \ldots, x_{p'}) (I_\alpha, \cup_\alpha J_\alpha) \coprod \ldots \coprod \coprod (p_1 + \ldots + p_{n-1} + [1, p_n]), \]

which identifies with the projection \( C^p_{z, N, q} \to \bigotimes_{\alpha} C^{p_\alpha}_{|I_\alpha|, |J_\alpha|, 1} \).

Extending formula \[ \text{identifying } \] defining \( d^p_{z, N, q} \), we define a map

\[ \tilde{d}^p_{z, N, q} : (\mathcal{L}(a_1, \ldots, x_{p'})^{\otimes q})_{[1, z+N]} \coprod \ldots \coprod \coprod (1, p'), \]

\[ \to (\mathcal{L}(a_1, \ldots, a_{z+N}, x_1, \ldots, x_{p'+1})^{\otimes q})_{[1, z+N]} \coprod \ldots \coprod \coprod (1, p'+1), \]
It follows that the map $d_{z,N,q}^{p',p'+1} : C_{z,N,q}^{p'} \to C_{z,N,q}^{p'+1}$ may be identified with the composite map\footnote{We lighten the notation by writing $X_{I_0,J_0,P_0}$ instead of $X_{I_0,J_0 \cup P_0}$.}

$$
\bigoplus_{\substack{\alpha \in [1, z-N] \\
\cup_{\sigma} J_\sigma = \emptyset}} \bigotimes_{\alpha=1}^q (\bigotimes_{\alpha_1=p_1+\ldots+p_{\alpha-1}+1}^{\alpha} \mathcal{L}(a_1, \ldots, a_{p_1})_{I_\alpha,J_\alpha,P_\alpha}) 
$$

As the partitions $(\tilde{I})_0, (J_0)_0, (P_0)_0$ to the summand indexed by \(((I_\alpha)_0, (J_\alpha)_0, (P_\alpha)_0)\), where $(P_\alpha)_0$ is the partition of $[1, p'+1]$ given by $P_\alpha = \left( (P_0 \cap [2,i]) - 1 \cup (P_0 \cap [i+1, p'+1]) \right)$ if $i \notin P_0$, and the union of the same set with $\{i\}$ if $i \in P_0$ (all these unions are disjoint); 

- $d_{z}^{p'}$ takes the summand indexed by \(((I_\alpha)_0, (J_\alpha)_0, (P_\alpha)_0)\) to the summand indexed by \(((I_\alpha)_0, (J_\alpha)_0, (P_\alpha^i)_0)\), where $(P_\alpha^i)_0$ is the partition of $[1, p'+1]$ given by $P_\alpha^i = \left( (P_0 \cap [1,i-1]) \cup ((P_0 \cap [i, p']) + 1) \right)$ if $i \notin P_0$, and the union of the same set with $\{i\}$ if $i \in P_0$ (all these unions are disjoint).

As the partitions $(I_0)_0$ and $(J_0)_0$ of $[1, z]$ and $z + [1, N]$ are not modified, \ref{X_1} is a decomposition of complexes. If $(P_0)_0$ is one of the partitions $(P_\alpha)_0$ or $(P_\alpha^i)_0$, then the sequence $(P_\alpha)_0$ has the form $(p_0 + \delta_{\alpha, \beta})_0$, where $\beta \in [1, q]$ and $p_0 = |P_0|$.

Fix $\beta \in [1, q]$ and set $p_0^\beta := p_0 + \delta_{\alpha, \beta}$. The partition $(P_\alpha)_0$ coincides with $(p_\alpha^\beta + \ldots + p_{\alpha-1}^\beta + [1, p_0^\beta])_0$ if:

(a) $P_0 = 1 + p_1 + \ldots + p_{\alpha-1} + [1, p_0]$ if $\alpha < \beta$, $P_\beta = 1 + p_1 + \ldots + p_{\beta-1} + [1, p_{\beta-1}] \cup \{1\}$, $P_\alpha = p_1 + \ldots + p_{\beta-1} + [1, p_\beta]$ if $\alpha > \beta$ and $p_1 + \ldots + p_{\beta-1} + 1 \leq i \leq j \leq p_1 + \ldots + p_{\beta-1} + 1$; in that case, $(P_\alpha^\beta)_0$ is given by $P_\alpha^\beta = p_1 + \ldots + p_{\alpha-1} + [1, p_\alpha]$ for $\alpha < \beta$, $P_\beta^\alpha = p_1 + \ldots + p_{\beta-1} + [1, p_{\beta-1}] + 1$, and $P_\alpha^\beta = 1 + p_1 + \ldots + p_{\beta-1} + [1, p_\beta]$ if $\alpha > \beta$. In particular, $i < j$ belong to $P_\beta^\alpha$;

(b) $P_0 = p_1 + \ldots + p_{\alpha-1} + [1, p_\alpha]$ for any $\alpha$, $p_1 + \ldots + p_{\beta-1} + 1 \leq i \leq p_1 + \ldots + p_{\beta-1} + 1$ and $z' \in I_{\beta}$; in that case, $(P_\alpha^\beta)_0$ is given by $P_\alpha^\beta = p_1 + \ldots + p_{\alpha-1} + [1, p_\alpha]$ for $\alpha < \beta$, $P_\beta^\alpha = p_1 + \ldots + p_{\beta-1} + [1, p_{\beta-1}] + 1$, and $P_\alpha^\beta = 1 + p_1 + \ldots + p_{\beta-1} + 1 + 1$ if $\alpha > \beta$. In particular, $i \in P_\beta^\alpha$ and $z' \in I_{\beta}$.
Now let $\bigotimes_\alpha F_\alpha(a_1, ..., x_{p'})$ belong to $\bigotimes_\alpha \mathcal{L}(a_1, ..., x_{p'})_{I_{\alpha},J_{\alpha},p_1+...+p_{\alpha-1}+1,p_{\alpha}}$. The image of this element in $\mathcal{L}(a_1, ..., x_{p'})_{[1,z+N][1,p']}$ is $(\sum_{\sigma\in S_{p_1},...,p_q} e(\sigma)\sigma) \ast (\bigotimes_\alpha F_\alpha)$. Let us apply $d^{p'-p+1}$ to this element, and let us project the result to

$$\bigotimes_\beta \mathcal{L}(a_1, ..., x_{p'+1})_{I_{\beta},J_{\beta},p_1+...+p_{\beta-1}+1,p_{\beta}}$$

According to what we have seen, the nontrivial contributions to the summand indexed by $\beta$ are:

- for $i < j$ in $p_1 + ... + p_{\beta-1} + 1, p_{\beta} + 1$, the projection of $d^{i,j}(e(\sigma)\ast (\bigotimes_\alpha F_\alpha))$, where $\sigma$ is the shuffle permutation taking the $p_1 + ... + p_{\alpha-1} + 1, p_{\alpha}$ described in (a) above;
- for $i \in p_1 + ... + p_{\beta-1} + 1, p_{\beta} + 1$ and $z' \in I_{\beta}$, the projection of $d^{i,z'}(\bigotimes_\alpha F_\alpha)$, where $d^{i,z'}$ is the summand of $d^{i}_z \ast d^{p'-p+1}$ corresponding to $(i, z')$.

Let

$$d^{p_\beta,p_{\beta-1}+1}_{\beta} : \mathcal{L}(a_1, ..., x_{p'})_{I_{\beta},J_{\beta},p_1+...+p_{\beta-1}+1,p_{\beta}} \to \mathcal{L}(a_1, ..., x_{p'+1})_{I_{\beta},J_{\beta},p_1+...+p_{\beta-1}+1,p_{\beta}}$$

be the differential of the complex $C^\bullet_{[I_\beta],[J_\beta],1}$ and let $d^{i,j}_{\beta}$, $d^{i,z'}_{\beta}$ be its components. We have $d^{i,j}(e \ast (\bigotimes_\alpha F_\alpha)) = F_1 \otimes ... \otimes d^{j}_{\beta}(F_{\beta}) \otimes ... \otimes F_q$ (to prove this equality, note that the $x_s$ present in the $s$th factor of $e \ast (\bigotimes_\alpha F_\alpha)$ gets replaced by $[x_s, x_s]$ on both sides; the signs coincide since the “usual” indices of the variables $x_s$ are shifts of $i, j$ by the same quantity, and this does not alter $(-1)^{i+j+1}$, while $e(\sigma) = (-1)^{p_1 + ... + p_{\beta-1}}$; on the other hand, $d^{i,z'}(\bigotimes_\alpha F_\alpha) = (-1)^{p_1 + ... + p_{\beta-1}}F_1 \otimes ... \otimes d^{z'}_{\beta}(F_{\beta}) \otimes ... \otimes F_q$ (here the sign is due to the fact that the index of $x_s$ is, in the usual ordering, $i - (p_1 + ... + p_{\beta-1})$). It follows that the contribution to the summand indexed by $\beta$ is $(-1)^{p_1 + ... + p_{\beta-1}}F_1 \otimes ... \otimes d^{p_\beta,p_{\beta-1}+1}_{\beta}(F_{\beta}) \otimes ... \otimes F_q$. So the projection of

$$d^{p'-p+1}(\sum_{\sigma\in S_{p_1},...,p_q} e(\sigma)\sigma) \ast (\bigotimes_\alpha F_\alpha)$$

as was to be proved.

As $z \neq 0$, for each partition $(I_1, ..., I_q)$ of $[1, z]$, there exists $i$ such that $|I_i| \neq 0$. So renaming $|I_i|$, $|I_j|$ by $z, N$, it suffices to prove that if $z \neq 0$, then $C^\bullet_{z,N,1}$ is acyclic.

Recall that $C^\bullet_{z,N,1} \simeq \mathcal{L}(a_1, ..., x_{p'})_{[1,z+N][1,p']} \ast d^{p'-p+1}_{z,N,1}$ is given by (15). On the other hand, the map $a \mapsto \text{ad}(a)(a_1)$ gives rise to an isomorphism

$$A^\bullet_{z,N,1} : \mathcal{L}(a_1, ..., x_{p'})_{[1,z+N][1,p']} \simeq C^\bullet_{z,N,1},$$

where $A(u_1, ..., u_n)$ is the free associative algebra generated by $u_1, ..., u_n$ and $\text{ad} : A(u_1, ..., u_s) \to \text{End}(\mathcal{L}(u_1, ..., u_s))$ is the algebra morphism derived from the adjoint action of $\mathcal{L}(u_1, ..., u_s)$ on itself. The differential $d^{p'-p+1} : A^\bullet_{z,N,1} \to A^\bullet_{z,N,1}$ is given
by
\[ Q(a_2, \ldots, a_{z+N}, x_1, \ldots, x_{p'}) \mapsto \sum_{1 \leq i < j \leq p'+1} (-1)^{i+j+1} Q(a_2, \ldots, a_{z+N}, [x_i, x_j], x_1, \ldots, \tilde{x}_i, \ldots, \tilde{x}_j, \ldots, x_{p'+1}) \]
\begin{align*}
&+ \sum_{i=1}^{p'+1} (-1)^{i+1} \left( Q(a_2, \ldots, a_{z+N}, x_1, \ldots, \tilde{x}_i, \ldots, x_{p'+1}) x_i \\
&\quad + \sum_{z'=2}^{z} Q(a_2, \ldots, [x_i, a_{z'}], \ldots, a_{z+N}, x_1, \ldots, \tilde{x}_i, \ldots, x_{p'+1}) \right),
\end{align*}
(16)
as \( \text{ad}(a)(x, a_1) = \text{ad}(ax)(a_1) \), for any \( x \in \mathcal{L}(a_1, \ldots, x_{p'}) \) and \( a \in \mathcal{A}(a_1, \ldots, x_{p'}) \).

We have an isomorphism
\[ \mathcal{A}_{z,N,1}^{p'} \cong \bigoplus_{\sigma \in \text{Perm}([2,\ldots,z+N])} \mathcal{A}_{\sigma}^{p'}, \]
where \( \mathcal{A}_{\sigma}^{p'} := (\mathcal{A}(x_1, \ldots, x_{p'}) \otimes z+N \mathcal{I})_{[1,p']}^{\mathcal{I}} \), whose inverse is the direct sum of the maps induced by
\[ \bigotimes_{\alpha=1}^{z+N} Q_{\alpha}(x_1, \ldots, x_{p'}) \mapsto Q_1(x_1, \ldots, x_{p'}) a_{\alpha(2)} Q_2(x_1, \ldots, x_{p'}) a_{\alpha(3)} \cdots a_{\alpha(z+N)} Q_{z+N}(x_1, \ldots, x_{p'}). \]
The explicit formula (16) shows that if \( Q(a_1, \ldots, x_{p'}) \) is a multilinear monomial, then the image of \( Q \) by the extension of \( \mathcal{A}_{z,N,1}^{p'} \) given by the same formula is a linear combination of monomials, where the \( a_i \) appear in the same order as in \( Q(a_1, \ldots, x_{p'}) \). It follows that for each \( \sigma \in \text{Perm}([2,\ldots,z+N]) \), \( \mathcal{A}_{\sigma}^{p'} \) is a subcomplex of \( \mathcal{A}_{z,N,1}^{p'} \), and that we have a direct sum decomposition of the complex \( \mathcal{A}_{z,N,1}^{p'} \),
\[ \mathcal{A}_{z,N,1}^{p'} \cong \bigoplus_{\sigma} \mathcal{A}_{\sigma}^{p'}. \]

The acyclicity of \( \mathcal{A}_{z,N,1}^{p'} \) is then a consequence of that of each subcomplex \( \mathcal{A}_{\sigma}^{p'} \), which we now prove. Let us fix \( \sigma \in \text{Perm}([2,\ldots,z+N']) \). There is a unique linear map
\[ \tilde{d}_{\sigma}^{p',p'+1} : (\mathcal{A}(x_1, \ldots, x_{p'}) \otimes z+N)_{[1,p']} \rightarrow (\mathcal{A}(x_1, \ldots, x_{p'+1}) \otimes z+N)_{[1,p'+1]}, \]
given by
\[ \tilde{d}_{\sigma}^{p',p'+1} \left( [x_1, x_j] \right) = \sum_{1 \leq i < j \leq p'+1} (-1)^{i+j+1} \tilde{Q}([x_i, x_j], x_1, \ldots, \tilde{x}_i, \ldots, \tilde{x}_j, \ldots, x_{p'+1}) \]
\[ + \sum_{i=1}^{p'+1} (-1)^{i+1} \left( \tilde{Q}(x_1, \ldots, \tilde{x}_i, \ldots, x_{p'+1})(\sum_{\alpha \in [\sigma^{-1}(2, z)]^{-1}} x_i^{(\alpha)} \bigotimes_{\alpha \in [\sigma^{-1}(2, z)]^{-1}} \tilde{Q}(x_1, \ldots, \tilde{x}_i, \ldots, x_{p'+1})) \right), \]
where \( f^{(\alpha)} = 1 \otimes f \otimes 1 \otimes z+N-\alpha \). If we set \( \epsilon_1 = 0, \epsilon_{z+N+1} = 1 \), and
\[ \epsilon_\alpha = 1 \Leftrightarrow \sigma(\alpha) \in [2, z], \quad \epsilon_\alpha = 0 \Leftrightarrow \sigma(\alpha) \in z+[1, N], \]
(18)
for $\alpha \in [2, z + N]$, then this map is

$$
\tilde{Q}(x_1, \ldots, x_{p'}) \mapsto \sum_{1 \leq i < j \leq p' + 1} (-1)^{i+j+1} \tilde{Q}([x_i, x_j], x_1 \ldots \hat{x}_i \ldots \hat{x}_j \ldots, x_{p'+1})
$$

\[ \alpha \epsilon E \]

The morphisms

$$
\text{Lemma 6.6.}
$$

Proof. For $\epsilon, \epsilon' \in \{0, 1\}$, define the “elementary” complexes $\mathcal{E}_{\epsilon, \epsilon}'$, as follows. We set $\mathcal{E}_{\epsilon, \epsilon}' := A(x_1, \ldots, x_{p'})_{[1, p']}$, and define $d_{\epsilon, \epsilon}'^{p'+1} : \mathcal{E}_{\epsilon, \epsilon}'^{p'} \to \mathcal{E}_{\epsilon, \epsilon}'^{p'+1}$ by

$$
(d^p_{\epsilon, \epsilon}' + 1)E(x_1, \ldots, x_{p'+1}) := \sum_{1 \leq i < j \leq p' + 1} (-1)^{i+j+1} E([x_i, x_j], x_1 \ldots \hat{x}_i \ldots \hat{x}_j \ldots, x_{p'+1})
$$

\[ \alpha \epsilon E \]

\[ \alpha \epsilon E \]

The map $d^p_{\epsilon, \epsilon}'$ then restricts to a linear map between the subspaces of totally antisymmetric tensors (under the actions of $\mathfrak{g}_{p'}$ on the left side and $\mathfrak{g}_{p'+1}$ on the right side), which coincides with $d^p_{\epsilon, \epsilon}'$.

For $\epsilon, \epsilon' \in \{0, 1\}$, define the “elementary” complexes $\mathcal{E}_{\epsilon, \epsilon}'$, as follows. We set $\mathcal{E}_{\epsilon, \epsilon}' := A(x_1, \ldots, x_{p'})_{[1, p']}$, and define $d_{\epsilon, \epsilon}'^{p'+1} : \mathcal{E}_{\epsilon, \epsilon}'^{p'} \to \mathcal{E}_{\epsilon, \epsilon}'^{p'+1}$ by

$$
(d^p_{\epsilon, \epsilon}' + 1)E(x_1, \ldots, x_{p'+1}) := \sum_{1 \leq i < j \leq p' + 1} (-1)^{i+j+1} E([x_i, x_j], x_1 \ldots \hat{x}_i \ldots \hat{x}_j \ldots, x_{p'+1})
$$

\[ \alpha \epsilon E \]

\[ \alpha \epsilon E \]

\[ \alpha \epsilon E \]

Lemma 6.5. For $\epsilon, \epsilon' \in \{0, 1\}$, $\mathcal{E}_{\epsilon, \epsilon}' := (\mathcal{E}_{\epsilon, \epsilon}', d_{\epsilon, \epsilon}'^{p'+1})_{p' \geq 0}$ is a complex.

Proof. Note first that for any $p' \geq 0$, $\mathcal{E}_{\epsilon, \epsilon}'$ is 1-dimensional, spanned by $e_{p'}(x_1, \ldots, x_{p'}) := \sum_{\sigma \in S_{p'}} e(\sigma) x_{\sigma(1)} \ldots x_{\sigma(p')}$. If $\mathfrak{g}$ is a Lie algebra, let $U(\mathfrak{g})_{\epsilon, \epsilon'}$ be the universal enveloping algebra of $\mathfrak{g}$, equipped with the trivial $\mathfrak{g}$-module structure if $(\epsilon, \epsilon') = (0, 0)$, the left (resp., right) regular $\mathfrak{g}$-module structure if $(\epsilon, \epsilon') = (1, 0)$ (resp., $(0, 1)$), and the adjoint $\mathfrak{g}$-module structure if $(\epsilon, \epsilon') = (1, 1)$. Let $(C_{\epsilon, \epsilon}'(\mathfrak{g}), d_{\epsilon, \epsilon}'^{p'+1}(\mathfrak{g}))$ be the cochain complex computing the cohomology of $\mathfrak{g}$ in these modules. We have $C_{\epsilon, \epsilon}'(\mathfrak{g}) = \text{Hom}(\Lambda^{p'}(\mathfrak{g}), U(\mathfrak{g}))$. There is a unique linear map $\mathcal{E}_{\epsilon, \epsilon}' \to C_{\epsilon, \epsilon}'(\mathfrak{g})$, taking $e_{p'}$ to the composite map $\Lambda^{p'}(\mathfrak{g}) \to \mathfrak{g}^\otimes p' \to U(\mathfrak{g})$, where the last map is the product map, and one checks that the diagram

$$
\begin{array}{ccc}
\mathcal{E}_{\epsilon, \epsilon}' & \xrightarrow{d_{\epsilon, \epsilon}'^{p'+1}} & \mathcal{E}_{\epsilon, \epsilon}'^{p'+1} \\
\downarrow & & \downarrow \\
C_{\epsilon, \epsilon}'(\mathfrak{g}) & \xrightarrow{d_{\epsilon, \epsilon}'^{p'+1}(\mathfrak{g})} & C_{\epsilon, \epsilon}'^{p'+1}(\mathfrak{g})
\end{array}
$$

commutes. Since $C_{\epsilon, \epsilon}'(\mathfrak{g})$ is a complex, and there exists a Lie algebra $\mathfrak{g}$ such that the morphisms $\mathcal{E}_{\epsilon, \epsilon}' \to C_{\epsilon, \epsilon}'(\mathfrak{g})$ are injective (for example, $\mathfrak{g}$ is a free Lie algebra with countably many generators), $\mathcal{E}_{\epsilon, \epsilon}'$ is also a complex. □

Lemma 6.6. We have an isomorphism of complexes $\mathcal{A}_{\alpha} \simeq \mathcal{E}_{\epsilon_{2}, \epsilon_{3}} \otimes \mathcal{E}_{\epsilon_{2}, \epsilon_{3}} \otimes \cdots \otimes \mathcal{E}_{\epsilon_{2} + N, 1}$, where $(\epsilon_{2}, \ldots, \epsilon_{z+N})$ is as in $[18]$. 
Proof. The proof is parallel to that of Lemma [6.3]. Let us set
\[ A'(x_1, \ldots, x_{p'}) := (A(x_1, \ldots, x_{p'})^\otimes z + N)_{[1, p']}. \]
If \( p_1 + \ldots + p_{z+N} = p' \), set
\[ A_{p_1, \ldots, p_{z+N}} := \bigotimes_{\alpha=1}^{z+N} A(x_1, \ldots, x_{p'})_{[1, p_1+\ldots+p_{\alpha-1}+1+p_\alpha]} \]
and if \( \bigsqcup_{\alpha=1}^{z+N} P_\alpha = [1, p'] \), set
\[ \tilde{A}_{p_1, \ldots, p_{z+N}} := \bigotimes_{\alpha=1}^{z+N} A(x_1, \ldots, x_{p'}) P_\alpha. \]
We have a decomposition
\[ \bigoplus_{p_1 + \ldots + p_{z+N} = p'} A_{p_1, \ldots, p_{z+N}} \simeq A'(x_1, \ldots, x_{p'}). \]
We will define the support of an element \( x \) of \( A'(x_1, \ldots, x_{p'}) \) as the set of partitions \( (P_1, \ldots, P_{z+N}) \) of \([1, p']\) such that the component \( x(P_1, \ldots, P_{z+N}) \) is nonzero. We also have natural morphisms \( A_{p_1, \ldots, p_{z+N}} \to A' \), given by \( x \mapsto (\sum_{\sigma \in \mathcal{G}_P} \epsilon(\sigma) \sigma) \cdot x \), where \( \star \) is the permutation action of \( \mathcal{G}_P \) on \( x \). The direct sum of these morphisms gives rise to an isomorphism
\[ \bigoplus_{p_1 + \ldots + p_{z+N} = p'} A_{p_1, \ldots, p_{z+N}} \simeq A'(x_1, \ldots, x_{p'}). \]
As the l.h.s. identifies with \( \bigoplus_{p_1 + \ldots + p_{z+N} = p'} E_{\epsilon_{[p_1]} \otimes \ldots \otimes E_{[p_{z+N} + 1, 1]} \epsilon} \), we obtain the identification \( A_* \simeq \bigotimes_{\alpha=1}^{z+N} \bigotimes_{\epsilon \in \mathcal{G}_{p_\alpha}} A'_{\alpha-1} \) at the level of graded vector spaces. We now show that this identification is compatible with the differentials.

The composite map
\[ \bigoplus_{\sum P_{\alpha} = p'} A_{p_1, \ldots, p_{z+N}} \simeq \]
\[ \bigoplus_{\sum P_{\alpha} = p'} A' \xrightarrow{\text{can}} \tilde{A} \xrightarrow{\pi} \bigoplus_{\sum P_{\alpha} = p'} A_{[1, p_1]+[1, p_2], \ldots, [1, p_{z+N}+1]+[1, p_{z+N}]} \]
where the last map is the projection along the components indexed by the other (nonconsecutive) partitions, is the canonical inclusion map. It follows that the map
\[ (\bigotimes_{\alpha} E_{\epsilon_{\alpha, \epsilon_{\alpha+1}}} \epsilon)^{p' + 1} \to (\bigotimes_{\alpha} E_{\epsilon_{\alpha, \epsilon_{\alpha+1}}} \epsilon)^{p' + 1} \]
may be identified with the composite map
\[ \bigoplus_{\sum P_{\alpha} = p'} A_{p_1, \ldots, p_{z+N}} \simeq \]
\[ \bigoplus_{\sum P_{\alpha} = p'} A' \xrightarrow{\text{can}} \tilde{A} \xrightarrow{\pi} \bigoplus_{\sum P_{\alpha} = p'+1} A_{[1, p_1], \ldots, [1, p_{z+N}+1]+[1, p_{z+N}]} \]
Now let \( Q_\alpha \in E_{\epsilon_{\alpha, \epsilon_{\alpha+1}}} \simeq A(x_1, \ldots, x_{p'})_{[1, p_1+\ldots+p_{\alpha-1}+1+p_\alpha]} \) and \( Q := \bigotimes_{\alpha} Q_\alpha \in A_{p_1, \ldots, p_{z+N}} \). The image of this element in \( A' \) is \( (\sum_{\sigma \in \mathcal{G}_P} \epsilon(\sigma) \sigma) \cdot Q \). The summand \( \epsilon(\sigma) \sigma \cdot Q \) belongs to \( \tilde{A}_{p_1, \ldots, p_{z+N}} \), where \( P_{\alpha} := (p_1 + \ldots + p_{\alpha-1} + [1, p_\alpha]) \).
Decompose $\tilde{d}_{\sigma}^p p^\gamma + 1 : \tilde{A}^\prime \rightarrow \tilde{A}^\prime + 1$ as a sum $\tilde{d}_{\sigma}^p p^\gamma + 1 = \sum_{1 \leq i < j \leq p^\gamma + 1} \tilde{d}_{ij} + \sum_{i=1}^{p^\gamma + 1} \sum_{\alpha \in [1,z+N]} \tilde{d}_{\alpha}^p$. If $\bigcup_{P} P_{\alpha} = [1,p']$, then $\tilde{d}_{ij}(\tilde{A}_{P_{\alpha}^{p^\gamma} \cup p^{\gamma + 1}}) \subset \tilde{A}_{P_{\alpha}^{p^\gamma} \cup p^{\gamma + 1}}$, and $\tilde{d}_{\alpha}^p(\tilde{A}_{P_{\alpha}^{p^\gamma} \cup p^{\gamma + 1}}) \subset \tilde{A}_{P_{\alpha}^{p^\gamma} \cup p^{\gamma + 1}}$, where

- $\tilde{d}_{ij}$ gives by $P_{ij}^\alpha := ((P_{\alpha} \cap [2,i]) - 1) \cup (P_{\alpha} \cap [i+1,j-1]) \cup ((P_{\alpha} \cap [j,p']) + 1)$ if $1 \not\in P_{\alpha}$, and the union of the same set with $\{i,j\}$ if $1 \in P_{\alpha}$;
- $\tilde{d}_{\alpha}^p$ gives by $P_{\alpha}^\alpha := (P_{\alpha} \cap [1,i-1]) \cup ((P_{\alpha} \cap [i,p']) + 1)$ if $\gamma \neq \alpha$, and the union of the same set with $\{i\}$ if $\gamma = \alpha$.

Note that the sequences $|P_{ij}^\gamma|, |P_{ij}^\gamma + 1|$ and $|P_{ij}^\alpha|, |P_{ij}^\alpha + 1|$ are necessarily of the form $(p_1^\beta, ..., p_{z+N}^\beta) := (p_1 + \delta_{1\beta}, ..., p_{z+N} + \delta_{z+N,\beta})$, where $\beta \in [1,z+N]$ is the index such that $1 \in P_{\alpha}$ in the first case, and $\alpha$ in the second case. Then:

- For any $i,j (1 \leq i < j \leq p^\gamma + 1)$ and any $\alpha \in [1,z+N]$, $(P_{ij}^\beta)$ coincides with $[1,p_1^\beta] \cdots [1,p_{z+N}^\beta + 1] [1,p_{z+N}^\beta + 1]$ if $P_{\alpha} = 1 + p_1 + \cdots + p_{\alpha-1} + 1, P_{\alpha}$ for $\alpha < \beta$, $P_{\beta} = (1 + p_1 + \cdots + p_{\beta-1} + 1, P_{\beta-1} + 1)$, and $P_{\alpha} = p_1 + \cdots + p_{\alpha-1} + 1, P_{\alpha}$ for $\beta > \alpha$, and $i \in P_{\alpha} + 1, p_{\beta-1} + 1$;
- For any $i \in [1,p^\gamma + 1]$ and $\alpha \in [1,z+N]$, $(P_{ij}^\alpha)$ coincides with $[1,p_1^\beta] \cdots [1,p_{z+N}^\alpha + 1]$ if $P_{\alpha} = p_1 + p_{\alpha-1} + 1, P_{\alpha}$ for any $\alpha$ and $i \in P_{\alpha} + 1, p_{\alpha-1} + 1$.

If $i,j$ are such that $1 \leq i < j \leq p^\gamma + 1$, then the condition on $\sigma = \tilde{d}_{\gamma}^p (\sigma) * Q$ in a consecutive partition of $[1,p^\gamma + 1]$ is therefore: there exists $\beta \in [1,z+N]$ such that $i,j \in p_1 + p_{\beta-1} + 1, P_{\beta} + 1$, and $\sigma$ is the shuffle permutation taking $[1,p_1], [1,p_1] + 1, [1,p_2] + 1, \cdots, [1,p_{z+N} - 1] + 1, [1,p_{z+N}]$ to the partition described in (a) above.

If $i \in [1,p^\gamma + 1]$ and $\alpha \in [1,z+N]$, then the condition on $\sigma = \tilde{d}_{\gamma}^p (\sigma) * Q$ in a consecutive partition of $[1,p^\gamma + 1]$ is therefore: $\sigma = id$ and $i \in p_1 + p_{\alpha-1} + 1, P_{\alpha} + 1$.

In the first case, we have $\epsilon(\sigma) = (-1)^{p_1 + \cdots + p_{\beta-1}}$ and $\pi \circ \tilde{d}_{\beta}^p (Q) = Q_1 \cdots \tilde{d}_{\beta}^p (Q_\beta) \cdots Q_{z+N}$; in the second case, $\pi \circ \tilde{d}_{\beta}^p (Q) = (-1)^{p_1 + \cdots + p_{\beta-1}} Q_1 \cdots \tilde{d}_{\beta}^p (Q_\beta) \cdots Q_{z+N}$. Here

$$\tilde{d}_{\beta}^p : A(x_1, ..., x_{p^\gamma + 1} + [1,p_{\beta}]) \rightarrow A(x_1, ..., x_{p^\gamma + 1} + [1,p_{\beta}])$$

is decomposed as

$$\tilde{d}_{\beta}^p = \sum_{1 \leq i < j \leq p^\gamma + 1} \tilde{d}_{ij} + \sum_{i=1}^{p^\gamma + 1} \tilde{d}_{\alpha}^p.$$  

Then

$$\pi \circ \tilde{d}_{\gamma}^p \circ \text{can}(Q) = \sum_{\beta=1}^{z+N} (-1)^{p_1 + \cdots + p_{\beta-1}} Q_1 \cdots \tilde{d}_{\beta}^p Q_{\beta} \cdots Q_{z+N},$$

which proves our claim.

$$\square$$

**Proposition 6.1.** The complexes $\mathcal{E}_{1,1}$ and $\mathcal{E}_{1,0}$ are acyclic; moreover, for $\epsilon \in \{0,1\}$, $H^p (\mathcal{E}_{\epsilon,\epsilon})$ is zero for any $p' \neq 0$ and $k$ for $p' = 0$.

**Proof.** If $u_1, ..., u_n$ are free variables, let $k = A_{<0}(u_1, ..., u_n) \subset \cdots \subset A_{\leq i}(u_1, ..., u_n)$ be the increasing PBW filtration of $A_{\leq i}(u_1, ..., u_n)$, induced by its identification with $U(\mathcal{L}(u_1, ..., u_n))$. The symmetrization isomorphism $A(u_1, ..., u_n) \simeq S(\mathcal{L}(u_1, ..., u_n))$ identifies $A_{\leq i}(u_1, ..., u_n)$ with
\[ \bigoplus_{i \leq i} S^i(\mathcal{L}(u_1, \ldots, u_n)). \] The graded space associated to this filtration is the free Poisson algebra \( \mathcal{P}(u_1, \ldots, u_n) = S(\mathcal{L}(u_1, \ldots, u_n)) \); its degree \( i \) part is \( \mathcal{P}[i](u_1, \ldots, u_n) = S^i(\mathcal{L}(u_1, \ldots, u_n)). \)

Define a filtration on \( \mathcal{E}_{e,e'} \) by \( F_u(\mathcal{E}_{e,e'}) := A_{\leq u}(x_1, \ldots, x_{p'})_{[1,p']_{e,e'}} \) for \( u \geq 0 \). If \( E(x_1, \ldots, x_{p'}) \in A_{\leq u}(x_1, \ldots, x_{p'})_{[1,p']_{[1,p']_{e,e'}}} \), then:

\[ E([x_i, x_j], x_1, \ldots, \hat{x}_i \ldots \hat{x}_j, \ldots, x_{p'+1}) \in A_{\leq u}(x_1, \ldots, x_{p'+1})_{[1,p']_{[1,p']_{e,e'}}}; \]

\[ x_i E(x_1, \ldots, x_{p'+1}), E(x_1, \ldots, x_{p'+1})x_i \in A_{\leq u+1}(x_1, \ldots, x_{p'+1})_{[1,p']_{[1,p']_{e,e'}}}, \]

while \( [x_i, E(x_1, \ldots, x_{p'+1})] \in A_{\leq u}(x_1, \ldots, x_{p'+1})_{[1,p']_{[1,p']_{e,e'}}}. \) It follows that for \( \epsilon \in \{0, 1\} \), we have

\[ d^{p',p'+1}_{e,e'}(F_u(\mathcal{E}_{e,e'})) \subset F_u(\mathcal{E}_{e,e'}), \]

while for \( \epsilon \neq \epsilon' \) in \( \{0, 1\} \),

\[ d^{p',p'+1}_{e,e'}(F_u(\mathcal{E}_{e,e'})) \subset F_{u+1}(\mathcal{E}_{e,e'}). \]

The associated graded complex is \( \mathcal{P}_{e,e'}^* \), where

\[ \mathcal{P}_{e,e'} = \mathcal{P}(x_1, \ldots, x_{p'})_{[1,p']_{e,e'}} = \bigoplus_{u \geq 0} \mathcal{P}[u][x_1, \ldots, x_{p'})_{[1,p']_{e,e'}}, \]

with differential

\[ \text{gr } d^{p',p'+1}_{e,e'} : \mathcal{P}_{e,e'} \to \mathcal{P}_{e,e'} \]

given by

\[ (\text{gr } d^{p',p'+1}_{e,e'}) P(x_1, \ldots, x_{p'+1}) := \sum_{1 \leq i < j \leq p'+1} (-1)^{i+j+1} P([x_i, x_j], x_1, \ldots, \hat{x}_i \ldots \hat{x}_j, \ldots, x_{p'+1}) + \epsilon \sum_{i=1}^{p'+1} (-1)^i \{x_i, P(x_1, \ldots, x_{p'+1})\} \]

for \( \epsilon \in \{0, 1\} \),

\[ (\text{gr } d^{p',p'+1}_{0,1}) P(x_1, \ldots, x_{p'+1}) := \sum_{i=1}^{p'+1} (-1)^{i+1} x_i P(x_1, \ldots, \hat{x}_i, \ldots, x_{p'+1}), \]

and \( \text{gr } d^{p',p'+1}_{1,0} = -\text{gr } d^{p',p'+1}_{0,1} \) (when \( \epsilon' = \epsilon \), the commutators give rise to brackets in the associated graded differential, while if \( \epsilon \neq \epsilon' \), the only part of the differential with nontrivial contribution to the associated graded differential is the second line of \( (21) \)). The differentials \( \text{gr } d^{p',p'+1}_{e,e'} \) have degree 0, and the differentials \( \text{gr } d^{p',p'+1}_{e,e'} \) have degree 1 (if \( \epsilon' \neq \epsilon \)) with respect to the \( \mathbb{N} \)-grading on \( \mathcal{P}_{e,e'}^* \) induced by \( (21) \). We therefore have direct sum decompositions of complexes

\[ \mathcal{P}_{e,e'} = \bigoplus_{u \in \mathbb{Z}} \mathcal{P}_{e,e'}[u], \quad \mathcal{P}_{e,e'} = \bigoplus_{u \in \mathbb{N}} \mathcal{P}_{e,e'}[u] \quad (\text{if } \epsilon' \neq \epsilon), \]

where for any \( \epsilon, \epsilon' \), we set \( \mathcal{P}_{e,e'}[u] := \mathcal{P}[u](x_1, \ldots, x_{p'})_{[1,p']_{e,e'}} \) and \( \mathcal{P}_{e,e'}[u] := \mathcal{P}_{e,e'}[u+p']. \)
Lemma 6.7. For \( n, u \geq 0 \), \( P_{c,e}^n[u] \) have the following values: \( \bullet \) if \( n = 2m \), \( P_{c,e}^{2m}[m] \) is 1-dimensional, spanned by

\[
p_{2m}(x_1, \ldots, x_{2m}) := \sum_{\sigma \in \mathfrak{S}_{2m}} \epsilon(\sigma) \{x_{\sigma(1)}, x_{\sigma(2)}\} \ldots \{x_{\sigma(2m-1)}, x_{\sigma(2m)}\}
\]

and \( P_{c,e}^{2m}[u] = 0 \) for \( u \neq m \);

\( \bullet \) if \( n = 2m + 1 \), \( P_{c,e}^{2m+1}[m+1] \) is 1-dimensional, spanned by

\[
p_{2m+1}(x_1, \ldots, x_{2m+1}) := \sum_{\sigma \in \mathfrak{S}_{2m+1}} \epsilon(\sigma)x_{\sigma(1)} \{x_{\sigma(2)}, x_{\sigma(3)}\} \ldots \{x_{\sigma(2m)}, x_{\sigma(2m+1)}\},
\]

and \( P_{c,e}^{2m+1}[u] = 0 \) for \( u \neq m + 1 \).

Proof of Lemma. As the category of \( \mathfrak{S}_n \)-modules is semisimple, the \( \mathfrak{S}_n \)-modules \( A(x_1, \ldots, x_n)[{1, 2}] \) and \( P(x_1, \ldots, x_n)[{1, 2}] \) are equivalent. It follows that \( P(x_1, \ldots, x_n)_{\mathfrak{S}_n}^{-}[1, 2] \) is 1-dimensional. Since this space is equal to \( \bigoplus_{u \geq 0} P[u](x_1, \ldots, x_n)_{\mathfrak{S}_n}^{-} \), it follows that exactly one of these summands is 1-dimensional, and the others are zero. It then remains to prove that \( p_n \in P_{c,e}^n[(n + 1)/2] \) and \( p_n \neq 0 \), where \( [x] \) is the integral part of \( x \).

If \( n = 2m \), we have

\[
p_{2m}(x_1, \ldots, x_{2m}) = 2^{-m} \sum_{\sigma \in \mathfrak{S}_{2m}} \epsilon(\sigma) \{x_{\sigma(1)}, x_{\sigma(2)}\} \ldots \{x_{\sigma(2m-1)}, x_{\sigma(2m)}\},
\]

so \( p_{2m} \) is \( \mathfrak{S}_n \)-anti-invariant, so \( p_{2m} \in P_{c,e}^{2m}[m] \); and if \( \Gamma \) is the set of \( \sigma \in \mathfrak{S}_{2m} \), such that \( \sigma(1) < \sigma(3) < \ldots < \sigma(2m-1) \) and \( \sigma(2i+1) < \sigma(2i+2) \) for \( i = 0, \ldots, m-1 \) (this identifies with the set of partitions of \([1, 2m]\) into subsets of cardinality 2, modulo a permutation of the subsets), we have

\[
p_{2m}(x_1, \ldots, x_{2m}) = m! \sum_{\sigma \in \Gamma} \epsilon(\sigma) \{x_{\sigma(1)}, x_{\sigma(2)}\} \ldots \{x_{\sigma(2m-1)}, x_{\sigma(2m)}\},
\]

and as the summands in this expression are linearly independent, \( p_{2m} \neq 0 \).

If \( n = 2m + 1 \), we have similarly

\[
p_{2m+1}(x_1, \ldots, x_{2m+1}) = 2^{-m} \sum_{\sigma \in \mathfrak{S}_{2m+1}} \epsilon(\sigma)x_{\sigma(1)} \{x_{\sigma(2)}, x_{\sigma(3)}\} \ldots \{x_{\sigma(2m)}, x_{\sigma(2m+1)}\},
\]

which implies that \( p_{2m+1} \) is \( \mathfrak{S}_n \)-anti-invariant, and

\[
p_{2m+1}(x_1, \ldots, x_{2m+1}) = m! \sum_{\sigma \in \Gamma} \epsilon(\sigma)x_{\sigma(1)} \{x_{\sigma(2)}, x_{\sigma(3)}\} \ldots \{x_{\sigma(2m)}, x_{\sigma(2m+1)}\},
\]

where \( \Gamma \) is the set of permutations \( \sigma \in \mathfrak{S}_n \) such that \( \sigma(2) < \sigma(4) < \ldots < \sigma(2m) \) and \( \sigma(2i) < \sigma(2i+1) \) for \( i = 1, \ldots, m \), which implies that \( p_{2m+1} \) is nonzero, as the summands in this expression are linearly independent. \( \square \)

End of proof of Proposition 6.1. For \( u \in \mathbb{Z} \), the complex \( P_{0,1}^1\{u\} \) is 0 \( \rightarrow \) \( P_{0,1}^0[u] \rightarrow \) \( P_{0,1}^1[u+1] \rightarrow \ldots \). For \( u > 0 \), the groups of this complex are all zero, so \( P_{0,1}^1\{u\} \) is acyclic. For \( u \leq 0 \), this complex is 0 \( \rightarrow \) \( \ldots \) \( \rightarrow \) \( P_{0,1}^0[m] \rightarrow \) \( P_{0,1}^1[m+1] \rightarrow \) \( 0 \rightarrow \ldots \), where \( m = -u \). The nontrivial map in this complex is \( p_{2m} \mapsto \text{gr} \) \( d_{0,1}^{2m,2m+1}(p_{2m}) = p_{2m+1} \), which is an isomorphism, so \( P_{0,1}^1\{u\} \) is acyclic. It

\[8\] Recall that for \( n_1 + \ldots + n_k = n \), \( \mathfrak{S}_{n_1,\ldots,n_k} = \{\sigma | \forall i \in [1,k], \sigma(n_1 + \ldots + n_{i-1} + 1) < \ldots < \sigma(n_1 + \ldots + n_k)\} \subseteq \mathfrak{S}_n \) is the set of \((n_1,\ldots,n_k)\)-shuffle permutations.
follows that $\mathcal{P}_{0,1}^*$ is acyclic. As the differential of $\mathcal{P}_{1,0}^*$ is the negative of that of $\mathcal{P}_{0,1}^*$, $\mathcal{P}_{1,0}^*$ is acyclic as well.

Let $\epsilon \in \{0,1\}$ and $u \in \mathbb{N}$. The complex $\mathcal{P}_{\epsilon,\epsilon}^*[u]$ is $0 \to \mathcal{P}_{\epsilon,\epsilon}^0[u] \to \mathcal{P}_{\epsilon,\epsilon}^1[u] \to \ldots$; if $i = u$, this complex is $0 \to k \to 0 \to 0 \to \ldots$, whose cohomology is 1-dimensional, concentrated in degree 0; if $u > 0$, this complex is $0 \to \ldots \to 0 \to \mathcal{P}_{\epsilon,\epsilon}^{2u-1}[u] \to \mathcal{P}_{\epsilon,\epsilon}^{2u}[u] \to 0 \to 0 \to \ldots$; the nontrivial map in this complex is $d_{2u-1} \Rightarrow gr d_{2u-1,2u}(p_{2u-1}) = up_{2u}$ if $\epsilon = 0$ and $-up_{2u}$ if $\epsilon = 1$. As this is an isomorphism in both cases, $\mathcal{P}_{\epsilon,\epsilon}^*[u]$ is acyclic for $u > 0$. It follows that the cohomology of $\mathcal{P}_{\epsilon,\epsilon}^*$ is 1-dimensional, concentrated in degree 0.

This implies that $\mathcal{E}_{\epsilon,\epsilon}^*$ is acyclic for $\epsilon \neq \epsilon'$, and that the cohomology of $\mathcal{E}_{\epsilon,\epsilon}^*$ is concentrated in degree 0. As $d_{0,1}^0 = 0$, we have in degree 0, $H^0(\mathcal{E}_{\epsilon,\epsilon}^*) = \mathcal{E}_{\epsilon,\epsilon}^0 \simeq k$. □

**Remark 3.** If $g$ is a Lie algebra, we have natural maps

$$H^*(\mathcal{E}_{\epsilon,\epsilon}^*) \to H^*(g, U(g)_{\epsilon,\epsilon'}).$$

When $(\epsilon, \epsilon') = (0,1)$ and $g$ is finite dimensional, then $H^n(g, U(g)_{0,1}) = k$ if $n = \dim g$, and $= 0$ otherwise. Indeed, if $C^n(g) := \wedge^n g \otimes U(g)$, then the differential $d_{g,n+1}^n : C^n(g) \to C^{n+1}(g)$ is given by $\omega \otimes x \mapsto \delta(\omega) \otimes x + \sum_{n=1}^{\dim g} (\omega \wedge e^n) \otimes (e_\alpha x)$, where $(e^n)_\alpha, (e_\alpha)_n$ are dual bases of $g^*$ and $g$ and $\delta : \wedge^n g^* \to \wedge^{n+1} g^*$ is induced by the Lie coalgebra structure of $g^*$. For $i \in \mathbb{Z}$, set $F_i(C^n(g)) := \wedge^n g^* \otimes U(g)_{<n+i}$ (where the last term is the subspace of elements of degree $\leq n + i$ for the PBW filtration). Then $d_{g,n+1}^n F_i(C^n(g)) \subset F_i(C^{n+1}(g))$, so $\ldots \subset F_i(C^n(g)) \subset \ldots \subset C^n(g)$ is a complete filtration of $C^n(g)$. The associated graded complex is $\hat{C}^n(g) := \wedge^n g^* \otimes S(g)$, with differential $\hat{d}_{g,n+1}^n : \hat{C}^n(g) \to \hat{C}^{n+1}(g)$, $\omega \otimes x \mapsto \sum_{n=1}^{\dim g} (\omega \wedge e^n) \otimes (e_\alpha x)$. This complex only depends on the vector space structure of $g$; if we denote it by $\hat{C}^*(g)$, then we have an isomorphism $\hat{C}^*(g_1 \oplus g_2) \simeq \hat{C}^*(g_1) \otimes \hat{C}^*(g_2)$, so $\hat{C}^*(g) \simeq C^*(k)^{\otimes \dim g}$. As the cohomology of $\hat{C}^*(k)$ is 1-dimensional, concentrated in degree 1, the cohomology of $\hat{C}^*(g)$ is 1-dimensional, concentrated in degree $\dim g$.

It follows that $\hat{C}^n(g)$ is acyclic in degree $\neq \dim g$, and its cohomology in degree $\dim g$ has dimension $\leq 1$. If $\omega \in \wedge^{\dim g} g$ is nonzero, then $\omega \otimes 1 \in C^0(g)$ is a nontrivial cocycle, so the cohomology of $\hat{C}^*(g)$ coincides with that of $\hat{C}^*(g)$. As $U(g)_{1,0} \simeq U(g)_{0,1}$ (using the antipode), we have $H^*(g, U(g)_{1,0}) \simeq H^*(g, U(g)_{0,1})$.

When $\epsilon \neq \epsilon'$, (22) is the zero map. If $\epsilon = \epsilon'$, then the map $k = H^0(\mathcal{E}_{\epsilon,\epsilon}^*) \to H^0(g, U(g)_{\epsilon,\epsilon})$ takes 1 to the class of $1 \in U(g)_{\epsilon,\epsilon}$ (which is invariant, both under the trivial and the adjoint actions of $g$ on $U(g)$).

**End of proof of Theorem 6.1** One of the pairs $(0, \epsilon_2), (\epsilon_2, \epsilon_3), \ldots, (\epsilon_{2+N}, 1)$ necessarily coincides with $(0,1)$; call it $(\epsilon_i, \epsilon_{i+1})$. According to Proposition 6.1, the corresponding complex $\mathcal{E}_{\epsilon_i,\epsilon_{i+1}}^*$ is then acyclic. Lemma 6.3 and the K"unneth formula then imply that $\mathcal{A}_{\epsilon_{i+1},N}^\sigma$ is acyclic. This being valid for any $\sigma$, the decomposition \(17\) then implies that $\mathcal{A}_{\epsilon_i,N,1}^\sigma$ is acyclic, as claimed.

## 7. Compatibility of quantization functors with twists

In this section, we prove the compatibility of quantization functors of quasi-Lie bialgebras with twists; we derive from there the compatibility of quantization functors of Lie bialgebras with twists (a result which was obtained in [EH] in the case of Etingof-Kazhdan quantization functors).
7.1. Twists of quasi-Lie bialgebras. Let $\text{QLBA}_f$ be the prop with the same generators as $\text{QLBA}$ with the additional $f \in \text{QLBA}_f(\Lambda^2, \text{id})$, and the same relations. This prop is $\mathbb{N}^2$-graded if we extend the degree $(\text{deg}_\mu, \text{deg}_\delta)$ of the generators of $\text{QLBA}$ by $f \mapsto (0, 1)$.

We then have $\text{QLBA}_f(X, Y) = \text{QLBA}(S(\Lambda^2) \otimes X, Y)$. The filtration of $\text{QLBA}_f$ induced by the degree $\text{deg}_\mu + \text{deg}_\delta$ is such that

$$\text{QLBA}_f^\geq n(X, Y) = \bigoplus_{k \geq 0} \text{QLBA}_f^{\geq n-k}(S^k(\Lambda^2) \otimes X, Y).$$

It follows that $\text{QLBA}_f(X, Y) \subset \text{QLBA}^{\geq v_f(|X|, |Y|)}(X, Y)$, where $v_f(|X|, |Y|) = \inf\{v(|X| + 2k, |Y| + k, k \geq 0)\}$ and $v(|X|, |Y|) = \frac{1}{2}|X| - |Y|$. As $v_f(|X|, |Y|) \geq v(|X|, |Y|$), $\text{QLBA}_f$ gives rise to a topological prop $\text{QLBA}_f$.

We have two prop morphisms $\kappa_i : \text{QLBA} \to \text{QLBA}_f$, defined by

$$\kappa_1 : \mu, \delta, \varphi \mapsto \mu, \delta, \varphi,$$

$$\kappa_2 : \mu \mapsto \mu, \quad \delta \mapsto \delta + \text{Alt}_2 \circ (\text{id}_\text{id} \otimes \mu) \circ (f \otimes \text{id}_\text{id}),$$

$$\varphi \mapsto \varphi + \frac{1}{2} \text{Alt}_3 \circ ((\delta \otimes \text{id}_\text{id}) \circ f + (\text{id}_\text{id} \otimes \mu \otimes \text{id}_\text{id}) \circ (f \otimes f));$$

this is the universal version of the operation of twisting of a quasi-Lie bialgebra structure. The prop morphisms $\kappa_i$ extend to topological props.

Let $(m, \Delta, \Phi, \eta, \epsilon)$ be a quantization functor for quasi-Lie bialgebras; so this is a quasi-bialgebra structure on $S$ in $\text{QLBA}$ as in Definition 3.2. For $i = 1, 2$, set $(m_i, \Delta_i, \Phi_i, \eta_i, \epsilon_i) := \kappa_i(m, \Delta, \Phi, \eta, \epsilon)$. Then $(m_i, \Delta_i, \Phi_i, \eta_i, \epsilon_i)$ are quasi-bialgebra structures on $S$ in $\text{QLBA}_f$.

**Proposition 7.1.** The quasi-bialgebra structures $(m_i, \Delta_i, \Phi_i, \eta_i, \epsilon_i)$ on $S$ in $\text{QLBA}$ are related by equivalence and twist.

This implies that the quantization functors of quasi-Lie bialgebras take quasi-Lie bialgebra related by a classical twist to quasi-Hopf QUE algebras related by a quantum twist.

**Proof.** The prop $\text{QLBA}_f$ is graded by $\text{deg}_3$. We have a prop morphism $\kappa_0 : \text{QLBA}_f \to \text{QLBA}_f/\langle f \rangle \simeq \text{QLBA}$; this morphism has degree 0 for $\text{deg}_3$.

**Lemma 7.1.** The linear map $H^0_{\text{QLBA}_f}(\text{id}, \Lambda^0) \to H^0_{\text{QLBA}}(\text{id}, \Lambda^0)$ induced by $\kappa_0$ is an isomorphism.

**Proof of Lemma.** The complexes computing these cohomology groups are $C^*_C = (C(\Lambda^*, \Lambda^0), [\mu, -])$ for $C = \text{QLBA}_f, \text{QLBA}$. As $\kappa_0(\mu) = \mu, \kappa_0$ induces a morphism $C^*_\text{QLBA}_f \to C^*_\text{QLBA}$. We will show that the relative complex $\text{Ker}(C^*_\text{QLBA}_f \to C^*_\text{QLBA})$ is acyclic, which implies the statement of the lemma.

If $I$ is a prop ideal in $C^*_\text{QLBA}_f$, we set $C^*_I := (I(\Lambda^*, \Lambda^0), [\mu, -])$. The relative complex is then $C^*_\langle \varphi \rangle_I$, where $\langle \varphi \rangle$ is the prop ideal of $\text{QLBA}_f$ generated by $\varphi$. This complex is graded by $\text{deg}_3$. As before, we have a filtration $C^*_\langle \varphi \rangle_I \supset C^*_\langle \varphi \rangle_{I'} \supset \ldots$, which is total in each degree. It suffices therefore to prove that the associated graded complex is acyclic. We now compute this graded complex.
Recall that if \( \langle \varphi \rangle \) is the ideal of \( \text{QLBA} \) generated by \( \varphi \), then \( \langle \varphi \rangle^0 / \langle \varphi \rangle^1(X, Y) = \text{LBA}(X, Y) \), and if \( k > 0 \), then \( \langle \varphi \rangle^k / \langle \varphi \rangle^{k+1}(X, Y) = \text{LBA}_\kappa(X, Y) \{ k \} = \text{Coker} \left( X \otimes S^{k-1}(\Lambda^3) \otimes \Lambda^4, Y \right) \rightarrow \text{LBA}(X \otimes S^k(\Lambda^3), Y) \), where \( \{ k \} \) means the grading \( (\mu, \delta, \varphi) \mapsto (0, 0, 1) \) on \( \text{LBA}_\kappa \).

Under the identification \( \text{QLBA}_{\kappa}(X, Y) \simeq \text{QLBA}(X \otimes S(\Lambda^2), Y) \), \( \langle \varphi \rangle^k(X, Y) \) identifies with \( \langle \varphi \rangle^k(X \otimes S(\Lambda^2), Y) \). Then if \( k > 0 \), we have \( \langle \varphi \rangle^k / \langle \varphi \rangle^{k+1}(X, Y) \simeq \langle \varphi \rangle^k / \langle \varphi \rangle^{k+1}(X \otimes S^{k-1}(\Lambda^3) \otimes \Lambda^4, Y) \rightarrow \text{LBA}(X \otimes S^k(\Lambda^3), Y) \).

It follows that the complex \( C_n^*(\langle \varphi \rangle^k / C_{n+1}^*(\varphi)^k \) identifies with \( \text{Coker} \left( \text{LBA}(\Lambda^* \otimes S(\Lambda^2) \otimes S^{k-1}(\Lambda^3) \otimes \Lambda^4, \Lambda^*) \right) \), equipped with the differential induced by \([\mu, -]\). Theorem 6.1 then implies that this complex is acyclic, as wanted. \( \square \)

As in Section 2.3, \( \deg_\delta \) gives rise to props \( \text{QLBA}_{\leq n} \), such that \( \text{QLBA}_{\leq 0} = \text{LA} \). The morphisms \( \kappa_i \) \( (i = 1, 2) \) have degree 0 for \( \deg_\delta \).

We define \( Q_n \) (resp., \( Q_n \)) as \{ quasi-bialgebra structures on \( S \) in \( \text{QLBA}_{\leq n} \) (resp., \( \text{QLBA}_{\leq n} \)) quantizing \( U(\text{id}_{\text{LA}}) \} / (\text{equivalence, twists}) \). The prop morphisms \( \kappa_i \) then induce maps \( \kappa_i^n : Q_n \rightarrow Q_n \) for \( i = 1, 2 \).

Lemma 7.2. \( \kappa_1^n = \kappa_2^n \).

Proof of Lemma. Since \( \kappa_0 \) induces \( \kappa_0^n : Q_n \rightarrow Q_n \), and since \( \kappa_0 \circ \kappa_i = \text{id} \), we have \( \kappa_0^n \circ \kappa_i^n = \text{id} \) for \( i = 1, 2 \). We also have a commutative diagram

\[
\begin{array}{ccc}
Q_n & \xrightarrow{\kappa_i^n} & Q_n \\
\pi \downarrow & & \downarrow \pi \\
Q_{n-1} & \xrightarrow{\kappa_{i-1}^n} & Q_{n-1}.
\end{array}
\]

Moreover, \( q_f \in \pi_f(Q_f^n) \) (resp., \( q \in \pi(Q_n) \)) being fixed, \( \pi_f^{-1}(q_f) \) (resp., \( \pi^{-1}(q) \)) is an affine space over \( H^3_{\text{QLBA}}[n] \) (resp., over \( H^3_{\text{QLBA}}[n] \)), and if \( q := \kappa_0^n(q_f) \), then the map \( \pi_f^{-1}(q_f) \rightarrow \pi^{-1}(q) \) is a morphism of affine spaces, compatible with the map \( H^3_{\text{QLBA}}[n] \rightarrow H^3_{\text{QLBA}}[n] \) induced by \( \kappa_0 \). Lemma 7.1 together with the formulas of Proposition 5.2 then imply that this map is bijective. It follows that the restriction of \( \kappa_0^n \) to a nonempty fiber of \( \pi_f \) is injective.

We now prove the statement by induction over \( n \). Let us assume that \( \kappa_i^{n-1} = \kappa_2^{n-1} \). Let \( \tilde{q} \in Q_n \) and let \( \tilde{q}_i := \kappa_i^n(\tilde{q}) \). Then \( \pi_f(\tilde{q}_i) = \kappa_i^{n-1}(\pi(\tilde{q})) = \kappa_2^{n-1}(\pi(\tilde{q})) = \pi_f(\tilde{q}_2) \) as \( \kappa_i^{n-1} = \kappa_2^{n-1} \). It follows that \( \tilde{q}_1, \tilde{q}_2 \) belong to the same fiber of \( \pi_f \). Now \( \kappa_0^n(\tilde{q}_1) = \tilde{q} = k_0^n(\tilde{q}_2) \). The injectivity of the restriction of \( \kappa_0^n \) to fibers of \( \pi_f \) then implies that \( \tilde{q}_1 = \tilde{q}_2 \); hence \( \kappa_1^n = \kappa_2^n \). \( \square \)

End of proof of Proposition 7.1 \[ \text{Now set } Q_\infty := \lim_\leftarrow Q_n, Q_\infty^f := \lim_\leftarrow Q_n^f. \] These sets identify with \{ quasi-bialgebra structures on \( S \) in \( \text{QLBA} \) (resp., \( \text{QLBA}_f \)) quantizing \( U(\text{id}_{\text{LA}}) \} / (\text{equivalence, twists}) \). The morphisms \( \kappa_i \) induce maps \( \kappa_\infty^i : Q_\infty \rightarrow Q_\infty^f \), and as \( \kappa_\infty^i = \lim_\leftarrow \kappa^n_i \), we have \( \kappa_\infty^i = \kappa_\infty^i \). As (class of \( (m, \Delta, \Phi) \)) = \( \kappa_\infty^i \) (class of \( (m, \Delta, \Phi) \)), the classes of \( (m_1, \Delta_1, \Phi_1) \) and \( (m_2, \Delta_2, \Phi_2) \) modulo equivalence and twists are the same. \( \square \)
7.2. Twists of Lie bialgebras. If \((A, m, \Delta)\) is a bialgebra in a symmetric tensor category \(C\), then a twist for \(A\) is an element \(F \in C(1, A^{\otimes 2})^\times\), such that \((\epsilon \otimes id_A) \circ F = (id_A \otimes \epsilon) \circ F = \eta\) and \((F \otimes \eta) \ast ((\Delta \otimes id_A) \circ F) = (\eta \otimes F) \ast ((id_A \otimes \Delta) \circ F)\). Then \((A, m, F \ast \Delta \ast F^{-1})\) is again a bialgebra in \(C\), called the twist of \(A\) by \(F\).

Let \(LBA_f\) be the prop of pairs \((a, f)\), where \(a\) is a Lie bialgebra and \(f \in \Lambda^2(a)\) is a Lie bialgebra twist (see \[EH\]): it has the same generators as \(LBA\) with the additional \(f \in LBA_f(1, \Lambda^2)\) and the same relations with the additional \(Alt_2 \circ ((\delta \otimes id_id) + (id_id \otimes \mu) \otimes id_id) \circ (f \otimes f)) = 0\). This prop is \(\mathbb{N}^2\)-graded if we extend \((\deg, \deg)\) of the generators of \(LBA\) by \(f \mapsto (0, 1)\), and it gives rise to a topological prop \(LBA_f\).

We then have prop morphisms \(\kappa_i^0 : LBA \to LBA_f (i = 1, 2)\), given by \(\kappa_i^0 : \mu, \delta \mapsto \mu, \delta\) and \(\kappa_i^0 : \mu, \delta \mapsto \mu, \delta + Alt_2 \circ (id_id \otimes \mu) \circ (f \otimes f)\), which extend to topological props.

Let \((m, \Delta, \eta, \epsilon)\) be a QF of Lie bialgebras; this is in particular a bialgebra structure on \(S\) in \(LBA\). We set \((m_i, \Delta_i, \eta_i, \epsilon_i) := \kappa_i^0(m, \Delta, \eta, \epsilon)\); these are bialgebra structures on \(S\) in \(LBA_f\).

The following statement was proved in \[EH\] when \((m, \Delta)\) is an Etingof-Kazhdan quantization functor.

**Proposition 7.2.** The bialgebra structures \((m_i, \Delta_i, \eta_i, \epsilon_i)\) are related by equivalence and a bialgebra twist.

**Proof.** Let \(\pi : QLBA \to QLBA / \langle \varphi \rangle \simeq LBA\) be the canonical morphism and \(\pi_f : QLBA_f \to LBA_f\) be the morphism defined by \(\mu, \delta, f, \varphi \mapsto \mu, \delta, f, 0\). We have commutative diagrams for \(i = 1, 2\)

\[
\begin{array}{ccc}
QLBA & \xrightarrow{\kappa_i} & QLBA_f \\
\pi \downarrow & & \pi_f \downarrow \\
LBA & \xrightarrow{\kappa_i^0} & LBA_f
\end{array}
\]

which extend to topological props. According to Theorem \[4.1\], the bialgebra structure \((m, \Delta)\) on \(S\) in \(LBA\) may be lifted to a quasi-bialgebra structure \((\tilde{m}, \tilde{\Delta}, \Phi)\) on \(S\) in \(QLBA\), so \(\pi(\tilde{m}, \tilde{\Delta}, \Phi) = (m, \Delta, \eta^\otimes 3)\). According to Proposition \[6.1\], the quasi-bialgebra structures \((\tilde{m}_i, \tilde{\Delta}_i, \Phi_i) := \kappa_i(\tilde{m}, \tilde{\Delta}, \Phi) (i = 1, 2)\) on \(S\) in \(QLBA_f\) are related by equivalence and twist, i.e., for some \(F \in QLBA_f(1, S^{\otimes 2})^\times\), \((\tilde{m}_2, \tilde{\Delta}_2, \Phi_2)\) is equivalent to \((\tilde{m}_1, \tilde{F} \ast \tilde{\Delta}_1 \ast \tilde{F}^{-1}, (\eta \otimes \tilde{F}) \ast ((id_S \otimes \tilde{\Delta}_1) \circ \tilde{F}) \ast ((\tilde{\Delta}_1 \otimes id_S) \circ \tilde{F})^{-1} \ast (\tilde{F} \otimes \eta)^{-1})\). As \(\pi_f \circ \kappa_i = \kappa_i^0 \circ \pi, \pi_f(\tilde{m}_i, \tilde{\Delta}_i, \Phi_i) = (m_i, \Delta_i, \eta^\otimes 3)\), so applying \(\pi_f\) to the above equivalence, we obtain (with \(F := \pi_f(\tilde{F})\)) that \((m_2, \Delta_2)\) is equivalent to \((m_1, F \ast \Delta_1 \ast F^{-1})\) and that \((\tilde{F} \otimes \eta) \ast ((\tilde{\Delta}_1 \otimes id_S) \circ \tilde{F}) = (\eta \otimes F) \ast ((id_S \otimes \Delta_1) \circ F)\), as wanted.

**Appendix A. Structure of the prop LBA.**

The following structure theorem of the prop \(LBA\) was proved in \[E, Pos\]. We reformulate here this proof using the language of props. In \[EH\], we derived Proposition \[5.1\] from Theorem \[A.1\] below.

**Theorem A.1.** If \(F, G \in Ob(Sch)\), then the map \(\bigoplus_{Z \in Irr(Sch)} LCA(F, Z) \otimes LA(Z, G) \to LBA(F, G)\) induced by composition and the prop morphisms \(LCA \to LA, LBA \to LA\) is a linear isomorphism.
It remains to show that each of the maps is injective.

Proof. It suffices to prove this when \( F, G \in \text{Irr}(\text{Sch}) \), and then (using the action of \( \mathfrak{S}_n, \mathfrak{S}_m \)) for \( F = T_n, G = T_m \). Using the cocycle relation and the isomorphism of the l.h.s. with \( \bigoplus_{z \geq 0} (\text{LA}(T_n, T_z) \otimes \text{LA}(T_z, T_m))_{\mathfrak{S}_z} \), one proves that the morphism is surjective. We now prove that it is injective. We have

\[
\text{LBA}(T_n, T_m) = \bigoplus_{a, b \geq 0 | a - b = n - m} \text{LBA}(T_n, T_m)[a, b]
\]

\[
= \bigoplus_{z \geq \min(n, m)} \text{LBA}(T_n, T_m)[z - m, z - n],
\]

and the morphism is the direct sum over \( z \geq \min(n, m) \) of the maps

\[
\bigoplus_{Z \in \text{Irr}(\text{Sch}) \mid |Z| = z} \text{LCA}(T_n, Z) \otimes \text{LA}(Z, T_m) \to \text{LBA}(T_n, T_m)[z - m, z - n].
\]

It remains to show that each of the maps is injective.

There is a unique morphism \( \text{LBA} \to L(\text{LCA}) \) (the generators of \( \text{LBA} \) are \( \mu, \delta, \) and the generator of \( \text{LCA} \) is \( \delta_{LCA} \)), taking \( \mu \) to \( \mu_{\text{free}} : L^{\otimes 2} \to L \) and \( \delta \) to the unique \( \delta_{\text{free}} : L \to L^{\otimes 2} \) such that \( \text{id} \to L \overset{\mu_{\text{free}}}{\longrightarrow} L^{\otimes 2} \) is \( \delta_{LCA} : \text{id} \overset{\delta_{\text{free}}}{\longrightarrow} L^{\otimes 2} \) and \( \delta \overset{\mu_{\text{free}}}{\longrightarrow} = ((\mu_{\text{free}} \otimes \text{id}_L) \circ (\text{id}_L \otimes \beta_{L,L}) + \text{id}_L \otimes \mu_{\text{free}}) \circ (\delta_{\text{free}} \otimes \text{id}_L) + (\mu_{\text{free}} \otimes \text{id}_L + (\text{id}_L \otimes \mu_{\text{free}}) \circ (\beta_{L,L} \otimes \text{id}_L) \circ (\text{id}_L \otimes \delta_{\text{free}})). \) The prop \( \text{LCA} \) is \( Z \)-graded, with \( \deg \delta_{LCA} = 1 \). Then the morphism \( \text{LBA} \to L(\text{LCA}) \) is compatible with the morphism \( Z^2 \to Z, (1, 0) \mapsto 0, (0, 1) \mapsto 1 \).

We then have maps \( \text{LBA}(T_n, T_m) \to L(\text{LCA})(T_n, T_m) = \text{LCA}(L^{\otimes n}, L^{\otimes m}) \to \text{LCA}(T_n, L^{\otimes m}), \) where the last map is induced by \( \text{id} \to L \), which restrict to \( \text{LBA}(T_n, T_m)[z - m, z - n] \to \text{LCA}(T_n, L^{\otimes m})[z - n] = \text{LCA}(T_n, (L^{\otimes m})_z) \), where the index \( z \) denotes the (Schur functor) degree \( z \) part.

Lemma A.1. If \( X \) is any prop and \( F \in \text{Ob}(\text{Sch}) \), we have an isomorphism \( X(F, (L^{\otimes m})_z) \simeq \bigoplus_{Z \in \text{Irr}(\text{Sch}) \mid |Z| = z} X(F, Z) \otimes \text{LA}(Z, T_m). \)

Proof of Lemma. We have isomorphisms \( \text{LA}(T_z, \text{id}) \simeq \text{multilinear part of the free Lie algebra in } z \text{ ordered generators } \simeq \text{Sch}(T_z, L_z) \). So if \( |Z| = z, \text{LA}(Z, \text{id}) \simeq \text{Sch}(Z, L_z) \), which may be expressed as \( L_z = \bigoplus_{i \mid |Z| = z} \text{LA}(Z, \text{id}) \otimes Z \).

So

\[
X(F, (L^{\otimes m})_z) = \bigoplus_{i \mid |Z_i| = z; \sum |Z_i| = z} \big( \bigoplus_{i \mid |Z_i| = z; \sum |Z_i| = z} X(F, Z_i) \otimes \big( \bigotimes_{i} \text{LA}(Z_i, \text{id}) \big) \big)
\]

\[
= \bigoplus_{i \mid |Z_i| = z; \sum |Z_i| = z} \big( \bigoplus_{i \mid |Z_i| = z; \sum |Z_i| = z} X(F, Z_i) \otimes \text{Sch}(Z, \bigotimes_{i} Z_i) \otimes \big( \bigotimes_{i} \text{LA}(Z_i, \text{id}) \big) \big)
\]

\[
= \bigoplus_{i \mid |Z_i| = z; \sum |Z_i| = z} \big( \bigoplus_{i \mid |Z_i| = z; \sum |Z_i| = z} X(F, Z) \otimes \text{LA}(Z, T_m) \big),
\]

where the last equality follows from

\[
\text{LA}(Z, T_m) = \bigoplus_{Z_1, ..., Z_m \in \text{Irr}(\text{Sch}) \mid \sum_i |Z_i| = z} \text{Sch}(Z, \bigotimes_{i} Z_i) \otimes \big( \bigotimes_{i} \text{LA}(Z_i, \text{id}) \big),
\]

for \( Z \in \text{Ob}(\text{Sch}) \) (see [EH]).

\[\square\]
End of proof of Theorem. We have constructed a map $LBA(T_n, T_m)[z - m, z - n] \to \bigoplus_{Z \in \text{Irr}(\text{Sch})} |z| LCA(T_n, Z) \otimes LA(Z, T_m)$, and one proves that is a section of the morphism $\bigoplus_{Z \in \text{Irr}(\text{Sch})} |z| LCA(T_n, Z) \otimes LA(Z, T_m) \to LBA(T_n, T_m)[z - m, z - n]$, which is therefore injective. □
