**p-Adic Periods and Derived de Rham Cohomology**

A. BEILINSON

To Irene

**Introduction**

For a smooth variety $X$ over a base field of characteristic 0 we have its algebraic de Rham cohomology $H^\dR(X) := H^\cdot(X_{\text{Zar}}, \Omega^\cdot_X)$; for nonsmooth $X$, one defines $H^\dR(X)$ using cohomological descent as in Deligne [D]. If the base field is $\mathbb{C}$, then one has the Betti cohomology $H^\cdot_B(X) := H^\cdot(X_{\text{cl}}, \mathbb{Q})$ and a canonical period isomorphism (“integration of algebraic differential forms over topological cycles”)  

$$
\rho : H^\dR(X) \xrightarrow{\sim} H^\cdot_B(X) \otimes \mathbb{C}
$$

compatible with the $\text{Gal}(\mathbb{C}/\mathbb{R})$-conjugation. To define $\rho$, consider the analytic de Rham cohomology $H^\dR_an(X)$. There are evident maps

$$
H^\dR(X) \xrightarrow{\alpha} H^\dR_an(X) \xleftarrow{\beta} H^\cdot_B(X) \otimes \mathbb{C}.
$$

Then $\beta$ is an isomorphism due to the Poincaré lemma, and $\rho := \beta^{-1}\alpha$ (the fact that $\rho$ is an isomorphism was established by Grothendieck [Gr]).

Suppose our base field is an algebraic closure $\bar{K}$ of a $p$-adic field $K$ (say, $K = \mathbb{Q}_p$). The role of $H^\cdot_B(X)$ is now played by the $p$-adic étale cohomology $H^\cdot_\eth(X, \mathbb{Q}_p)$, and Fontaine conjectured in [F1] the existence of a natural $p$-adic period isomorphism

$$
\rho : H^\dR(X) \otimes_{\mathbb{K}} B^{\dR} \xrightarrow{\sim} H^\cdot_\eth(X, \mathbb{Q}_p) \otimes B^\dR.
$$

Here $B^\dR$ is Fontaine’s $p$-adic periods field ([F1], [F3]). Recall that it is a complete discretely-valued field whose ring of integers $B^+_\dR$ contains $\bar{K}$, the residue field $B^\dR/m^\dR$ is Tate’s field $\mathbb{C}_p$, the cotangent line $m^\dR/m^2\dR$ is the Tate twist $\mathbb{C}_p(1)$. Both sides of (0.3) carry natural filtrations (coming from the filtration of $B^\dR$ by powers of $m^\dR$ and the Hodge-Deligne filtration on $H^\dR(X)$), and $\rho$ is compatible with them and with the $\text{Gal}(\bar{K}/K)$-conjugation. Moreover, as was envisioned by Fontaine and Jannsen ([F4], [J]), the matrix coefficients of $\rho$ lie in the subring $KB_{\text{st}}$ of $B^\dR$ and $\rho$ is compatible with the extra symmetries of log crystalline cohomology.
The \( p \)-adic period map was defined in three different ways in works of, respectively, Faltings, Niziol, and Tsuji (with prior crucial input of Bloch, Fontaine, Hyodo, Kato, Kurihara, and Messing: the nonproper setting was treated by Yamashita [Y]), see [Fa1, Fa2, N1, N2, Ts1, Ts2]; the three \( \rho \)'s coincide by [N3].

In the article we give another construction of \( \rho \) which is fairly direct and has the same flavor as the classical picture (0.2). The tools are derived de Rham cohomology of Illusie [H2] Ch. VIII] and de Jong’s alterations. The companion paper [B] treats the Fontaine-Jannsen side of the story; another approach was developed by Bhattacharya [Bh2]. It would be very interesting to see if these methods can help to understand the Riemann-Hilbert correspondence in the \( \rho \)-topology.

An outline of the construction: First we realize \( \mathrm{B}^+_{dR} \) as the ring of de Rham \( p \)-adic constants in the sense of derived algebraic geometry. Namely, let \( \Lambda_{dR} \) be the derived de Rham algebra \( L\Omega^\cdot \hat{\otimes}_{\hat{O}_K} \) completed with respect to the Hodge filtration \( F^- \); see [H2] Ch. VIII (2.1.3.3)]. Here \( O_K, \hat{O}_K \) are the rings of integers in \( K, \hat{K} \). Now \( \mathrm{B}^+_{dR} \) identifies canonically with \( \Lambda_{dR} \hat{\otimes} \hat{Q}_p \), where \( \hat{\otimes} \) is the derived completed tensor product, so that \( \mathfrak{m}_{dR}^- \sim F^1\Lambda_{dR} \hat{\otimes} \hat{Q}_p \). This fact was observed independently by Fargues [Far].

Let \( \mathcal{V} \) be the category of varieties over a field \( F \), and \( \mathcal{V}_{dR} \) be the category of regular \( F \)-varieties \( U \) equipped with a regular compactification \( \bar{U} \) with normal crossings divisor at infinity. As follows from de Jong’s theorem [dJ1], the forgetful functor \( \mathcal{V}_{dR} \to \mathcal{V}, (U, \bar{U}) \mapsto U \), makes \( \mathcal{V}_{dR} \) a base for the \( \eta \)-topology on \( \mathcal{V} \), so \( \hat{\mathcal{V}} \)-sheaves on \( \mathcal{V}_{dR} \) are the same as \( \hat{\mathcal{V}} \)-sheaves on \( \mathcal{V}_{dR} \) for the induced topology. For \( F = \hat{K} \) as above, there is a finer category \( \mathcal{V}_{dR}^{ss} \) of ss-pairs \((V, \bar{V})\), i.e., smooth \( \hat{K} \)-varieties \( V \) equipped with a semi-stable compactification \( \bar{V} \) (that includes compactification in the arithmetic direction). Again by de Jong [dJ1], \( \mathcal{V}_{dR}^{ss} \) is a base for the \( \eta \)-topology on \( \mathcal{V}^{\hat{K}} \).

Consider the presheaf on \( \mathcal{V}_{dR}^{ss} \) which assigns to \((V, \bar{V})\) the derived de Rham algebra with log singularities \( R\hat{\Gamma}(\bar{V}, L\Omega^\cdot_{(\hat{V}, V)/\hat{O}_K}) \) (see [Ol]). Its \( \hat{\mathcal{V}} \)-sheafification \( \mathcal{A}_{dR}^{\hat{K}} \) is an \( \hat{\mathcal{V}} \)-sheaf of filtered dg algebras on \( \mathcal{V}_{dR}^{\hat{K}} \) that contains the constant subsheaf \( \Lambda_{dR} \). The key \( p \)-adic Poincaré lemma says that the map \( \Lambda_{dR} \hat{\otimes} \mathbb{Z}/p^n \to A_{dR}^{\hat{K}} \hat{\otimes} \mathbb{Z}/p^n \) is a filtered quasi-isomorphism. It comes from the next assertion: The \( \hat{\mathcal{V}} \)-sheafification of the presheaf \((V, \bar{V}) \mapsto H^h(V, \Omega^\cdot_{(V,V)/\hat{O}_K})\), where \( \Omega^\cdot_{(V,V)/\hat{O}_K} \) is the usual locally free \( \hat{O}_V \)-module of forms with log singularities, is an \( \hat{\mathcal{V}} \)-sheaf of \( \mathbb{Q} \)-vector spaces for \((a, b) \neq (0, 0)\). The case \( a = 0 \) is essentially theorem 8.0.1 from Bhattacharya’s thesis [Bh1]; the general result is obtained by a similar method (which uses coverings of families of stable curves that come from the multiplication by \( p \) isogeny of the generalized Jacobians).

Set \( R\hat{\Gamma}_{dR}^{\hat{K}}(X) := R\hat{\Gamma}(X_\h, \mathcal{A}_{dR}^{\hat{K}}) \); this is the arithmetic de Rham complex of \( X \). By the above, \( H^h(R\hat{\Gamma}_{dR}^{\hat{K}}(X) \hat{\otimes} \hat{Q}_p) \) is a \( \hat{\mathcal{B}}_{dR}^{+} \)-algebra. One has a diagram

\[
\begin{align*}
H^h_{dR}(X) \xrightarrow{\alpha} H^h(R\hat{\Gamma}_{dR}^{\hat{K}}(X) \hat{\otimes} \hat{Q}_p) & \xrightarrow{\beta} H_{et}(X, \hat{Q}_p) \hat{\otimes} \hat{\mathcal{B}}_{dR},
\end{align*}
\]

where \( \alpha \) is the composition \( H^h_{dR}(X) \xrightarrow{\sim} H^h(R\hat{\Gamma}_{dR}^{\hat{K}}(X) \hat{\otimes} \hat{Q}_p) \) \( \xrightarrow{\sim} H^h(R\hat{\Gamma}_{dR}^{\hat{K}}(X) \hat{\otimes} \hat{Q}_p) \) and \( \beta \) is the \( \hat{\mathcal{B}}_{dR}^{+} \)-linear extension of the evident map (which comes from the embeddings \( \mathbb{Z}/p^n \to A_{dR}^{\hat{K}} \hat{\otimes} \mathbb{Z}/p^n \) and the fact that the \( \eta \)-topology is stronger than the étale one). Since the étale and \( \eta \)-cohomology with torsion coefficients coincide, the Poincaré lemma implies that \( \beta \) is an isomorphism. Now the \( p \)-adic period map \( \rho \) is
the $B_{dR}$-linear extension of $\beta^{-1}\alpha$. An explicit computation for $X = \mathbb{G}_m$ followed by usual tricks of the trade shows that $\rho$ is a filtered isomorphism.

1. A derived de Rham construction of $B_{dR}$

1.1. The derived $p$-adic completion. Throughout the article we use (not too heavily) $E_\infty$ algebras, for which we refer to, say, [HS]. Recall that $E_\infty$ algebras are dg algebras whose product is commutative and associative up to coherent higher homotopies (more formally, $E_\infty$ algebras are dg algebras for a resolution of the commutative algebra operad). A key fact: for any commutative (more generally, $E_\infty$) cosimplicial dg algebra the corresponding total complex is naturally an $E_\infty$ algebra. Thus the homotopy limit of a diagram of $E_\infty$ algebras is an $E_\infty$ algebra.

For a projective system of complexes of abelian groups $\ldots \rightarrow C_2 \xrightarrow{\partial_2} C_1$, one has $\operatorname{holim} C_n = \operatorname{Cone}(\operatorname{id} - \phi : \Pi C_n \rightarrow \Pi C_n)[-1]$, where $\phi(\{c_n\}) = (\phi_n(c_n+1))$. There is an embedding $\lim C_n = \operatorname{Ker}(\operatorname{id} - \phi) \hookrightarrow \operatorname{holim} C_n$. If all $\phi_n$'s are surjective, then $\operatorname{id} - \phi$ is surjective; hence $\rightarrow$ is a quasi-isomorphism. So $\operatorname{holim}$, being an exact functor, is the right derived functor of $\lim$.

If $C$ is a projective system of dg algebras, then $\operatorname{holim} C_n$ is naturally a dg algebra (and the above embedding is an embedding of algebras); if the $C_n$ are commutative (or, more generally, $E_\infty$) algebras, then $\operatorname{holim} C_n$ is an $E_\infty$ algebra.

Let $p$ be a prime. Consider the projective system of commutative dg algebras $C_n := \operatorname{Cone}(\Z \xrightarrow{p} \Z)$. It is a resolution of the projective system $\ldots \rightarrow \Z/p^2 \rightarrow \Z/p$, so $Z^p := \operatorname{holim} C_n$ is an $E_\infty$ algebra with $H^0 Z^p = \Z_p$ and acyclic in nonzero degrees.

Set $\Q^p := Z^p \otimes \Q$. For any complex $F$ of abelian groups set

$$(1.1.1) \quad F \hat{\otimes} Z_p := \operatorname{holim}(F \otimes C_n), \quad F \hat{\otimes} \Q_p := (F \otimes Z_p) \otimes \Q.$$ 

These are dg $Z_p$ and $\Q_p$-modules, so their cohomology groups are $Z_p$- and $\Q_p$-modules, and $F \rightarrow F \hat{\otimes} Z_p, F \hat{\otimes} \Q_p$ are exact functors. If $F$ is an $(E_\infty)$ dg algebra, then so are $F \hat{\otimes} Z_p$ and $F \hat{\otimes} \Q_p$.

Remark. One has an evident projective system $F_p[1] \rightarrow F \otimes C_n \rightarrow F/p^n F$ of exact triangles; applying holim, we get a canonical exact triangle $\operatorname{holim} F_p[1] \rightarrow F \hat{\otimes} Z_p \rightarrow \operatorname{holim}(F/p^n F)$. Let $\tilde{F} := \operatorname{holim} F/p^n F$ be the $p$-adic completion of $F$ and $T_p F := \operatorname{holim} F_p$ be the Tate module of $F$. By above, we have a quasi-isomorphism $\tilde{F} \sim \operatorname{holim}(F/p^n F)$. Thus if $F$ has no $p$-torsion, then $F \hat{\otimes} Z_p \sim \tilde{F}$. Similarly, if all components of $F$ are $p$-divisible, then one has quasi-isomorphisms $T_p F \sim \operatorname{holim} F_p$ and $T_p F[1] \sim F \hat{\otimes} Z_p$. We see that $\cdot \hat{\otimes} Z_p$ is the left derived functor of the $p$-adic completion functor and the right derived functor of $T_p[1]$.

Example. For a scheme $X$, its étale $Z_p$- and $\Q_p$-cohomology are $\Gamma_{\et}(X, Z_p) := \operatorname{holim} \Gamma(X_{\et}, Z/p^n) = \Gamma(X_{\et}, Z) \hat{\otimes} Z_p, \Gamma_{\et}(X, \Q_p) := \Gamma(X_{\et}, Z) \hat{\otimes} \Q_p$.

1.2. The derived de Rham algebra. For a morphism of commutative rings $A \rightarrow B$ we denote by $\Omega_{B/A}$ the relative de Rham complex of $B$ over $A$. This is a commutative dg $A$-algebra with components $\Omega^i_{B/A} = \Lambda^i_B \Omega_{B/A}$, where $\Omega_{B/A}$ is the $B$-module of relative Kähler differentials; it carries a ring filtration $F^n = \Omega^n_{B/A}$.

\footnote{In loc. cit. $E_\infty$ algebras are called “May algebras”.}

\footnote{Since $\Gamma(X_{\et}, Z/p^n) = \Gamma(X_{\et}, Z) \otimes^L Z/p^n$.}
We will use the $F$-completed version $L\Omega^i_{B/A}$ of Illusie’s derived de Rham algebra defined in [II12 Ch. VIII, (2.1.3.3)]. To construct it, consider the canonical simplicial resolution $P = P_1(B)$ of $B$ from [III Ch. I,(1.5.5.6)]. This is a simplicial commutative $A$-algebra such that each $P_i$ is a polynomial $A$-algebra. The de Rham complexes $\Omega^B_{P/A}$ form a simplicial filtered commutative dg $A$-algebra, so the corresponding total complex $L\Omega^i_{B/A}$ is a filtered commutative dg $A$-algebra (see [III Ch. I, 3.1.3]). Now $L\Omega^i_{B/A}$ is its completion with respect to the filtration $F^i$. Here “completion” is understood as a mere projective system of quotients modulo $F^i$. One has a natural identification gr$_i^pL\Omega^i_{B/A} \sim (L\Omega^i_{B/(L_{B/A})})[-i]$ compatible with the product; here $L_{B/A} := \Omega^B_{P/A} \otimes_P B$ is the relative cotangent complex and $L\Lambda^i_B$ is the nonabelian left derived functor of the exterior power functor (see Ch. II and Ch. I of [III]). For $A$-flat $B$’s, the construction is compatible with base change. It is compatible with direct limits. If in the above definition we replace $\Lambda^i_B$ by any simplicial $A$-algebra resolution of $B$ whose terms are polynomial $A$-algebras, then the output is naturally quasi-isomorphic to $L\Omega^i_{B/A}$.

The next lemma is a particular case of [III Ch. I, 4.3.2.1(ii)]. For a flat $B$-module $T$ we denote by $B(T)$ its divided powers symmetric algebra.

**Lemma.** The complex $L\Lambda^i_B(T[1])$ is acyclic outside degree $-i$. There is a canonical isomorphism of graded $B$-algebras compatible with base change

\[
H^{-j}L\Lambda^i_B(T[1]) \sim B(T^i).
\]

1.3. Let $K$ be a $p$-adic field, i.e., a complete discretely-valued field of characteristic zero with perfect residue field $\bar{k}$ of characteristic $p > 0$, $\bar{K}$ be an algebraic closure of $K$, and $O_K$, $O_{\bar{K}}$ be rings of integers in $K$, $\bar{K}$. Let $K_0 \subset K$ be the field of fractions of the Witt vectors $W(k) = O_{\bar{k}}$, and let $a$ be the fractional ideal in $\bar{K}$ generated by $p^{-\infty}D_{K/K_0}^{-1}$, where $D{K/K_0}$ is the different. For an $O_K$-algebra $B$ we often write $\Omega_B := \Omega_{B/O_K}$, $L_1B := L\Omega_B^{[O_K]}$, $L_B = L_{B/O_K}$, etc.

The next key result is due to Fontaine [F2 Th 1]: we include a proof for completeness sake. Consider the map $\mu_p \subset O^{\leq}_{\bar{K}} \xrightarrow{\frac{d\log}{\log}} O_{\bar{K}}$ and its $O_{\bar{K}}$-linear extension

\[
(\bar{K}/O_{\bar{K}})(1) = O_{\bar{K}} \otimes \mu_p \rightarrow O_{\bar{K}}.
\]

**Theorem.** One has $L_{O_K} \rightarrow O_{\bar{K}}$, and (1.3.1) is surjective with kernel $(a/O_{\bar{K}})(1)$.

**Proof.** If $K'/K$ is a finite extension, then $O_{K'}/O_K$ is a complete intersection. So, if $\pi$ is a generator of $O_{K'}/O_K$, $f(t)$ its minimal polynomial, then $L_{O_{K'}}$ is the cone of multiplication by $f'(\pi)$ endomorphism of $O_{K'}$; hence $L_{O_{K'}} \rightarrow O_{K'}$. Passing to the limit, we get the first assertion. Let us prove the second one.

(i) By the above, $\Omega_{O_{K'}} \sim O_{K'} \otimes K'/K$. If $K''/K'$ is another finite extension, then the standard exact triangle of the cotangent complexes reduces to a short exact sequence $0 \rightarrow O_{K''} \otimes O_{K'}/O_K \rightarrow \Omega_{O_{K''}/O_K} \rightarrow \Omega_{O_{K''}/O_{K'}} \rightarrow 0$.

(ii) Replacing $K'$, $K$ by $K$, $K_0$ and passing to the limit, we get a short exact sequence $0 \rightarrow O_{\bar{K}} \otimes O_K \rightarrow \Omega_{O_{\bar{K}}/O_K} \rightarrow \Omega_{O_{\bar{K}}/O_{K_0}} \rightarrow 0$. Thus it suffices to prove the theorem for $K = K_0$, which we now assume.

(iii) Set $T := \text{Ker}(\bar{K}/O_{\bar{K}})(1) \rightarrow \Omega_{\bar{K}}$, $\tilde{T} := K(\mu_p)$. The set of $O_{\bar{K}}$-submodules of $(\bar{K}/O_{\bar{K}})(1)$ is totally ordered by inclusion. Thus, since $O_{\bar{K}} \otimes O_F \subset O_{\bar{K}}$ is a nonzero $O_{\bar{K}}$-module generated by $d\log(\mu_p)$, one has $T \subset (p^{-1}O_{\bar{K}}/O_{\bar{K}})(1) = O_{\bar{K}} \otimes \mu_p$. Since $\Omega_{O_F}$ is isomorphic to $O_F/p^{1-\frac{1}{p}}O_{\bar{K}}$, one has $T = (p^{-1}O_{\bar{K}}/O_{\bar{K}})(1)$.
(iv) It remains to prove surjectivity of \((\hat{K}/O_{\hat{K}})(1) \to \Omega_{O_{\hat{K}}}\). Let \(K' \subset \hat{K}\) be any finite extension of \(K\); we want to check that \(\Omega_{O_{K'}} \subset \Omega_{O_{\hat{K}}}\) lies in \(O_{\hat{K}}d\log(\mu_{p^n})\). Suppose \(p^n\) kills \(\Omega_{O_{K'}}\). Let us show that \(\Omega_{O_{K'}} \subset O_{\hat{K}}d\log(\mu_{p^{n+1}})\). Set \(K' := K'(\mu_{p^{n+1}})\). The set of \(O_{K'}\)-submodules of \(\Omega_{O_{K'}}\) is totally ordered. Thus, since \(p^n d\log(\mu_{p^{n+1}}) \neq 0\) by (iii), \(\Omega_{O_{K'}}\) lies in \(O_{\hat{K}}d\log(\mu_{p^{n+1}})\), q.e.d. 

1.4. For a complex \(P\) acyclic in degrees \(\neq 0\), we often write \(P\) instead of \(H^0P\).

Consider the filtered commutative dg \(O_K\)-algebra \(A_{dR} = A_{dR,\hat{K}/K} := L\Omega_{\hat{K}}O_K\) and the corresponding filtered \(E_{\infty}\) \(O_K\)-algebra \(A_{dR} \hat{\otimes} \mathbb{Z}_p\) (see §1.1). Let us describe the graded \(O_K\)-algebras \(gr^X_{\hat{P}}A_{dR}\), \(gr_{\hat{P}}A_{dR} \hat{\otimes} \mathbb{Z}_p\).

**Proposition.** (i) The complexes \(gr^X_{\hat{P}}A_{dR} \hat{\otimes} \mathbb{Z}_p\) are acyclic in nonzero degrees, and there is a canonical isomorphism of graded algebras

\[
gr^X_{\hat{P}}A_{dR} \hat{\otimes} \mathbb{Z}_p \cong O_{\hat{K}}(\hat{a}(1)) .
\]

(ii) One has \(gr^0_{\hat{P}}A_{dR} = A_{dR}/F^1 = O_K\), and the complexes \(gr^i_{\hat{P}}A_{dR}\) for \(i > 0\) are acyclic in degrees \(\neq 1\). There are natural isomorphisms of \(O_K\)-modules

\[
\Omega^{(i)} := H^1gr^i_{\hat{P}}A_{dR} \hat{\cong} (\hat{K}/i!\cdot1^{\hat{a}}(1)) \circ \Omega_{O_{\hat{K}}}(1) = (\mathbb{Q}_p/\mathbb{Z}_p) \otimes i!\cdot1^{\hat{a}}(1).
\]

**Proof.** (i) By the theorem in §1.3, one has \(L \Omega_{O_K/O_K} \hat{\cong} \Omega_{O_{\hat{K}}}(1) = (\mathbb{Q}_p/\mathbb{Z}_p) \otimes (a(1))\); hence \(gr^i_{\hat{P}}A_{dR} \hat{\cong} LA^1_{L_p}(\mathbb{Q}_p/\mathbb{Z}_p)[i] \otimes \mathbb{Z}p^n\), which identifies with \(i!\cdot1^{\hat{a}}(1)\) in a way compatible with the product by (1.2.1). Therefore \(gr^X_{\hat{P}}A_{dR} \hat{\otimes} \mathbb{Z}_p \cong (\mathbb{Q}_p/\mathbb{Z}_p)(\hat{a}/p^n(1))^{\hat{a}}\), which yields (1.4.1).

(ii) follows from (i) by the next observation (applied to \(C = gr^X_{\hat{P}}A_{dR}\), with (1.4.2) defined by the condition that \(T_p(1.4.2) = (1.4.1)\)): If a complex \(C\) of abelian groups has \(p\)-torsion cohomology and \(H^p(C \otimes \mathbb{Z}_p) = 0\), then \(H^1C\) is \(p\)-divisible and \(H^pC = 0\).

1.5. By 1.4(i), the algebras \((A_{dR}/F^i) \hat{\otimes} \mathbb{Z}_p\), hence \((A_{dR}/F^i) \hat{\otimes} \mathbb{Q}_p\), are acyclic in nonzero degree. By loc. cit., \((A_{dR}/F^{i+1}) \hat{\otimes} \mathbb{Q}_p\) is an \(i\)-truncated dvr with residue field \(\mathbb{C}_p := \hat{O}_K \otimes \mathbb{Q}\), so \(A_{dR} \hat{\otimes} \mathbb{Q}_p := \varprojlim(A_{dR}/F^i) \hat{\otimes} \mathbb{Q}_p\) is a dvr. Let \(m_{\text{dR}}\) be its maximal ideal; (1.4.1) yields a canonical identification \(m_{\text{dR}}/m_{\text{dR}}^2 = gr^{1}_{\hat{P}}A_{dR} \hat{\otimes} \mathbb{Q}_p \hat{\cong} \mathbb{C}_p(1)\).

**Proposition.** There is a canonical ring isomorphism of filtered rings

\[
u_Q : B_{dR}^{+} \hat{\cong} \mathcal{A}_{dR} \hat{\otimes} \mathbb{Q}_p.
\]

**Proof.** The ring \((A_{dR}/F^{i+1}) \hat{\otimes} \mathbb{Z}_p\) is an infinitesimal \(p\)-adic \(O_K\)-thickening of \(\hat{O}_K = (A_{dR}/F^i) \hat{\otimes} \mathbb{Z}_p\) of order \(\leq i\) (see [F3] 1.1). Let \(A_{inf}/F^{i+1}\) be the universal thickening [F3 1.3]; we have a canonical map \(u_i : A_{inf}/F^{i+1} \to (A_{dR}/F^{i+1}) \hat{\otimes} \mathbb{Z}_p\). Since \(B_{dR}^{+}/F^{i+1} := (A_{inf}/F^{i+1}) \otimes \mathbb{Q}\) is an \(i\)-truncated dvr and \(u_i\) is an isomorphism by [F3] 1.4.3, \(u_Q : B_{dR}^{+}/F^{i+1} \hat{\cong} (A_{dR}/F^{i+1}) \hat{\otimes} \mathbb{Q}_p\). Set \(u_Q := \varprojlim u_{iQ}\).

**Remarks.** (i) The map \(A_{dR} \to A_{dR}/F^1 = O_K\) yields an isomorphism \(A_{dR} \hat{\otimes} \mathbb{Q} \hat{\cong} \hat{K}\). Thus the morphism \(A_{dR} \otimes \mathbb{Q} \to A_{dR} \hat{\otimes} \mathbb{Q}_p\) equals the usual embedding \(K \hookrightarrow B_{dR}^{+}\).

\[\text{Use the fact that every complex of abelian groups splits, i.e., is quasi-isomorphic to a complex with zero differential.}\]
(ii) For a finite extension $K'/K$, $K'\subset \hat{K}$, the evident map $A_{\text{dR}}K/\hat{K} \to A_{\text{dR}}K/K'$ yields an isomorphism $A_{\text{dR}}K/\hat{K} \hat{\otimes}_{p} \hat{\otimes}Q_p \simeq A_{\text{dR}}K/\hat{K} \hat{\otimes}Q_p$ compatible with (1.5.1).

1.6. The next result, which will not be used in the rest of the article, is a reinterpretation of Colmez’s theorem [Col]. It would be nice to find a simpler direct proof.

**Proposition.** The complexes $A_{\text{dR}}/F^i$ are acyclic in nonzero degrees; the maps $H^0(A_{\text{dR}}/F^{i+1}) \to H^0(A_{\text{dR}}/F^i)$ are injective. Set $O^{(i)} := H^0(A_{\text{dR}}/F^{i+1})$; thus $O_K = O^{(0)} \supset O^{(1)} \supset \ldots$ and $(A_{\text{dR}}/F^{i+1}) \hat{\otimes}Z_p$ is equal to the $p$-adic completion $\hat{O}^{(i)}$ of $O^{(i)}$.

**Proof.** By 1.4(ii), the exact cohomology sequence for $0 \to \text{gr}^i_{F}A_{\text{dR}} \to A_{\text{dR}}/F^{i+1} \to A_{\text{dR}}/F^i \to 0$ reduces to $0 \to O^{(i)} \to O^{(i-1)} \xrightarrow{d^{(i)}} \Omega^{(i)} \to H^1(A_{\text{dR}}/F^{i+1}) \to H^1(A_{\text{dR}}/F^i) \to 0$. So $O_K = O^{(0)} \supset O^{(1)} \supset \ldots$, and the vanishing of $H^1(A_{\text{dR}}/F^{i+1})$ amounts to that of $H^1(A_{\text{dR}}/F^i)$ combined with surjectivity of $d^{(i)} : O^{(i-1)} \to \Omega^{(i)}$.

It remains to prove that all $d^{(i)}$ are surjective.

Recall that Colmez [Col] considers a sequence of subalgebras $O_K = O^{(0)} \supset O^{(1)} \supset \ldots$ and derivations $d^{(i)} : O^{(i-1)} \to \Omega^{(i)}$ defined by induction: $d^{(i)}$ is a universal $O_K$-linear derivation with values in an $O_K$-module, and $O^{(i)} := \text{Ker} d^{(i)}$. An induction by $i$ shows that $O^{(i)} \supset O^{(i)}$: Indeed, $\Omega^{(i)}$ are $O_K$-modules and $d^{(i)} : O^{(i-1)} \to \Omega^{(i)}$ is a derivation; so, if $O^{(i-1)} \supset O^{(i-1)}$, then $d^{(i)}|_{O^{(i-1)}} = a^{(i)}d^{(i)}$ for some $O_K$-linear map $a^{(i)} : \Omega^{(i)} \to O^{(i)}$; thus $O^{(i)} \supset O^{(i)}$.

Let $i$ be the smallest number such that $d^{(i)}$ is not surjective. Since $E := \Omega^{(i)}/d^{(i)}(O^{(i-1)})$ is $p$-torsion $p$-divisible, one has $E \hat{\otimes}Z_p = T_pE \otimes Q \neq 0$. Applying $\hat{\otimes}Z_p$ to the exact triangle $O^{(i)} \to A_{\text{dR}}/F^{i+1} \to E[-1]$, we get a short exact sequence $0 \to O^{(i)} \to (A_{\text{dR}}/F^{i+1}) \hat{\otimes}Z_p \to T_pE \to 0$. By [Col], $A_{\text{inf}}/F^{i+1} = \hat{O}^{(i)}$.

By universality, the map $u_i : A_{\text{inf}}/F^{i+1} \to (A_{\text{dR}}/F^{i+1}) \hat{\otimes}Z_p$ equals the composition $\hat{O}^{(i)} \to \hat{O}^{(i)} \to (A_{\text{dR}}/F^{i+1}) \hat{\otimes}Z_p$, so its composition with the projection onto $T_pE$ vanishes. This cannot happen since $u_iQ$ is an isomorphism (see §1.5), q.e.d. □

2. **H-topology and semi-stable compactifications**

2.1. A **topological digression.** The next proposition is a generalization of [V2, 4.1].

Let $V$ be an essentially small site. As in [V1], we denote by $V^{-1}$ the corresponding topos (the category of sheaves of sets on $V$).

For us, a **base for $V$** is a pair $(B, \phi)$, where $B$ is an essentially small category and $\phi : B \to V$ is a faithful functor, that satisfies the next property:

(*). For any $V \in V$ and a finite family of pairs $(B_\alpha, f_\alpha)$, $B_\alpha \in B$, $f_\alpha : V \to \phi(B_\alpha)$, there exists a set of objects $B'_\beta \in B$ and a covering family $\{\phi(B'_\beta) \to V\}$ such that every composition $\phi(B'_\beta) \to V \to \phi(B_\alpha)$ lies in $\text{Hom}(B'_\beta, B_\alpha) \subset \text{Hom}(\phi(B'_\beta), \phi(B_\alpha))$.

**Remarks.** (i) Property (*) for an empty set of $(B_\alpha, f_\alpha)$'s means that every $V \in V$ has a covering by objects $\phi(B)$, $B \in B$. If $\phi$ is fully faithful, then (*) amounts to this assertion.

(ii) If $B$ admits finite products and $\phi$ commutes with finite products, then it suffices to check (*) for families $(B_\alpha, f_\alpha)$ having $\leq 1$ element.

---

The proposition below in this situation amounts to [V2, 4.1].
(iii) In the general case, it suffices to check (*) for families \((B_\alpha, f_\alpha)\) having \(\leq 2\) elements.

Suppose \((B, \phi)\) is a base for \(\mathcal{V}\). Define a covering sieve in \(B\) as a sieve whose \(\phi\)-image is a covering family in \(\mathcal{V}\).

**Proposition.** (i) Covering sieves in \(B\) form a Grothendieck topology on \(B\).

(ii) The functor \(\phi : B \to \mathcal{V}\) is continuous (see [V2 1.1]).

(iii) \(\phi\) yields an equivalence of the toposes: one has \(\mathcal{B}^- \overset{\sim}{\to} \mathcal{V}^-\).

We call the above topology on \(B\) the \(\phi\)-induced topology.\(^7\)

**Proof.** (i) Let us check that covering sieves in \(B\) are stable with respect to pullback; the rest of the axioms from [V1 1.1] are evident. For a morphism \(g : B' \to B\) in \(B\) and a covering sieve \(s\) on \(B\), let us find a covering family on \(B'\) that belongs to the \(g\)-pullback of \(s\). The \(\phi(g)\)-pullback of \(\phi(s)\) is a covering sieve in \(\mathcal{V}\), so there is a covering family \(\{\pi_\gamma : V_\gamma \to \phi(B')\}\) such that every composition \(V_\gamma \to \phi(B') \to \phi(B)\) can be factored as \(V_\gamma \xrightarrow{g_\gamma} \phi(B_\gamma) \xrightarrow{\phi(p_\gamma)} \phi(B)\), where \(p_\gamma : B_\gamma \to B\) belongs to \(s\). Applying (*) to \(V_\gamma\) and \((B', \pi_\gamma)\), we find a covering family \(\{\phi(B'_\gamma) \to V_\gamma\}\) as in (*). The composite covering \(\{\phi(B'_\beta) \to \phi(B')\}\) comes then from a covering family \(\{B'_\beta \to B'\}\) in \(B\) which lies in the \(g\)-pullback of \(s\).

(ii) We know that \(\phi\) sends covering families to covering families, so it suffices to show that for any given \(p_\alpha : B_\alpha \to B\) in \(B\) and \(f_\alpha : V \to \phi(B_\alpha)\), \(\alpha = 1, 2\), such that \(\phi(p_1) \cdot f_1 = \phi(p_2) \cdot f_2\) there is a covering \(\{\pi_\beta : V_\beta \to V\}\) and morphisms \(\xi_{\alpha\beta} : B'_\beta \to B_\alpha\), \(g_\beta : V_\beta \to \phi(B'_\beta)\) such that \(p_1 \xi_{1\beta} = p_2 \xi_{2\beta}\) and \(\phi(\xi_{\alpha\beta}) g_\beta = f_\alpha \pi_\beta\). Such a datum (with \(g_\beta\) the identity map) comes from (*) applied to \(V\) and \((B_1, f_1), (B_2, f_2)\).

(iii) By (ii), one has the usual adjoint functors between the categories of sheaves \((\phi^*, \phi_*) : \mathcal{B}^- \sto \mathcal{V}^-\). To prove that they are mutually inverse equivalences, we will check that for \(\mathcal{F} \in \mathcal{B}^-\) and \(\mathcal{G} \in \mathcal{V}^-\) the adjunction maps \(a_{\mathcal{F}} : \mathcal{F} \to \phi_* \phi^* \mathcal{F}, b_{\mathcal{G}} : \phi^* \phi_! \mathcal{G} \to \mathcal{G}\) are isomorphisms.

Recall that \(\phi^* \mathcal{F} = (\phi^\circ \mathcal{F})^\circ\), where \(\phi^\circ\) is the pullback of presheaves and \(\circ\) is the sheafification functor. For \(V \in \mathcal{V}\) one has \((\phi^\circ \mathcal{F})(V) = \text{colim}_{(V, p_\gamma)} \mathcal{F}\), where \(\mathcal{C}(V)\) is the category of pairs \((B, f)\), \(B \in B, f : V \to \phi(B)\), with \(\text{Hom}_{\mathcal{C}(V)}((B, f), (B', f')) := \{g \in \text{Hom}(B', B) : \phi(g) f' = f\}\), and we set \(\mathcal{F}(B, f) := \mathcal{F}(B)\).

(a) To show that \(a_{\mathcal{F}}\) is an isomorphism, we check that it is injective and surjective:

- \(a_{\mathcal{F}}\) is injective: Suppose we have \(B \in B\) and \(\xi_1, \xi_2 \in \mathcal{F}(B)\) such that \(a_{\mathcal{F}}(\xi_1) = a_{\mathcal{F}}(\xi_2)\); let us show that \(\xi_1\) coincides. One has
  \[
  a_{\mathcal{F}}(\xi_1) \in (\phi_\alpha \phi^* \mathcal{F})(B) = (\phi^* \mathcal{F})(\phi(B)),
  \]
  and the equality means that there is a covering \(\{\pi_\gamma : V_\gamma \to \phi(B)\}\) such that the images of \(\xi_1\) in \((\phi^\circ \mathcal{F})(V_\gamma) = \text{colim}_{(V_\gamma, p_\gamma)} \mathcal{F}\) coincide. Thus for some finite subdiagram \(\mathcal{C}(V_\gamma') \subset \mathcal{C}(V_\gamma)\) that contains \((B, p_\gamma)\) the images of \(\xi_1\) in \(\text{colim}_{(V_\gamma', p_\gamma')} \mathcal{F}\) coincide. Applying (*) to \(V_\gamma\) and pairs from \(\mathcal{C}(V_\gamma')\), we get a covering \(\{\phi(B'_\gamma) \to V_\gamma\}\) such that the image of \(\mathcal{C}(V_\gamma')\) in each \(\mathcal{C}(\phi(B'_\gamma))\) comes from a diagram in \(B'_\gamma / B'_\beta\). The composite covering \(\{\phi(B'_\beta) \to \phi(B)\}\) comes then from a covering \(\{B'_\beta \to B\}\) in \(B\), and the images of \(\xi_1\) in \(\mathcal{F}(B'_\beta)\) coincide. Then \(\xi_1 = \xi_2\) since \(\mathcal{F}\) is a sheaf, q.e.d.

\(^7\)The terminology is compatible with that of [V2 3.1].
\( a_F \) is surjective: For \( B \in \mathcal{B} \), \( \chi \in (\phi_\ast \phi^\ast F)(B) \) we look for a covering \( \{ B_\alpha' \to B \} \) in \( \mathcal{B} \) such that \( \chi|_{V_\alpha'} \) lies in the image of \( F(B_\alpha') \to (\phi_\ast \phi^\ast F)(B_\alpha') \). To find it, consider \( \chi \) as an element of \( (\phi^\ast F)(\phi(B)) \). There is a covering \( \{ \pi_\gamma : V_\gamma \to \phi(B) \} \) such that \( \chi|_{V_\gamma} \) lies in the image of \( (\phi^\ast F)(V_\gamma) \to (\phi^\ast F)(\phi(B_\gamma)) \); i.e., one has \( f_\gamma : V_\gamma \to \phi(B_\gamma) \) such that \( \chi|_{V_\gamma} \) lies in the image of the composition \( F(B_\gamma) \to (\phi^\ast F)(\phi(B_\gamma)) \to (\phi^\ast F)(V_\gamma) \), where the second arrow comes from \( f_\gamma \). Applying \((*)\) to \( V_\gamma \) and \( (B_\gamma, \pi_\gamma) \), \( (B_\gamma, f_\gamma) \), we find a covering \( \{ \phi(B_\alpha') \to V_\gamma \} \) as in \((*)\); the composite covering \( \phi(B_\alpha') \to \phi(B) \) comes then from a covering \( \{ B_\alpha' \to B \} \) that satisfies the promised property.

(b) \( b_\gamma \) is an isomorphism: Since \( a_\gamma (b_\gamma) a_{\phi, \gamma} = \text{id}_{\phi_\ast \gamma} \) and we already know that \( a_{\phi, \gamma} \) is an isomorphism, we see that \( \phi_\gamma (b_\gamma) : \phi_\gamma \phi^\ast \phi_\gamma (\gamma) \to \phi_\gamma \gamma \) is an isomorphism. Thus \( b_\gamma (B) : \phi^\ast \phi_\gamma \gamma (\gamma) \to \gamma (\gamma) \) is an isomorphism for every \( B \in \mathcal{B} \). Since every \( V \in \mathcal{V} \) admits a covering by objects \( \phi(B), B \in \mathcal{B} \), this implies that \( b_\gamma \) is both injective and surjective, hence an isomorphism, q.e.d.

Exercises. (i) For any presheaf \( J \) on \( \mathcal{V} \) one has \( \phi_\gamma (J) = (\phi, J)^\gamma \).

(ii) Suppose \((\mathcal{B}, \phi)\) is a base for \( \mathcal{V} \) and \((\mathcal{B}', \phi')\) is a base for the \( \phi \)-induced topology on \( \mathcal{B} \). Then \((\mathcal{B}', \phi')\) is a base for \( \mathcal{V} \).

2.2. For a field \( K \), let \( \mathcal{V}_{ar}^K \) be the category of \( K \)-varieties, i.e., reduced separated \( K \)-schemes of finite type. We will consider categories \( \mathcal{B} \) formed by varieties equipped with appropriate compactifications, referred to as pairs:

(a) Geometric setting: Let \( j : U \hookrightarrow \bar{U} \) be an open embedding such that \( \bar{U} \) is proper and \( U \) is dense in \( \bar{U} \). We call such a datum a geometric pair over \( K \), or geometric \( K \)-pair, and denote it by \((U, \bar{U})\). We say that \((U, \bar{U})\) is a regular normal crossings pair, nc-pair for short, if \( U \) is a regular scheme and \( \bar{U} \setminus U \) is a divisor with normal crossings in \( \bar{U} \); it is a strict nc-pair if the irreducible components of \( \bar{U} \setminus U \) are regular. A morphism \( f : (U', \bar{U}') \to (U, \bar{U}) \) of pairs is a map \( U' \to U \) which sends \( U' \) to \( U \). We denote the category of geometric \( K \)-pairs by \( \mathcal{V}_{ar}^K \); let \( \mathcal{V}_{ar}^{nc} \) be the full subcategory of nc-pairs.

(b) Arithmetic \( K \)-setting: Suppose \( K \) is a \( p \)-adic field as in §1.3. An arithmetic pair over \( K \), a.k.a. arithmetic \( K \)-pair, is an open embedding \( j : U \hookrightarrow \bar{U} \) with dense image of a \( K \)-variety \( U \) into a reduced proper flat \( O_K \)-scheme \( \bar{U} \).

For such a \((U, \bar{U})\) we set \( O_{K_U} := \Gamma(\bar{U}, \mathcal{O}_U) \), \( K_U := \Gamma(U_K, \mathcal{O}_U) \). Then \( K_U \) is the product of several finite extensions of \( K \) (labeled by the connected components of \( U_K \); if \( \bar{U} \) is normal, then \( O_{K_U} \) is the product of the corresponding rings of integers. The closed fiber \( U_s \) of \( \bar{U} \) is the union of fibers over the closed points of \( O_{K_U} \).

We say that \((U, \bar{U})\) is a semi-stable pair, or simply ss-pair, if (i) \( \bar{U} \) is a regular scheme, (ii) \( U \setminus \bar{U} \) is a divisor with normal crossings on \( U \), and (iii) the closed fiber \( U_s \) is reduced. Our ss-pair is strict if the irreducible components of \( U \setminus \bar{U} \) are regular. Arithmetic \( K \)-pairs form a category \( \mathcal{V}_{ar}^{nc}_K \); let \( \mathcal{V}_{ar}^{ss}_K \) be the full subcategory of ss-pairs.

(c) Arithmetic \( \bar{K} \)-setting: For \( K \) as in (b), let \( \bar{K} \) be its algebraic closure. An arithmetic pair over \( \bar{K} \), a.k.a. arithmetic \( \bar{K} \)-pair, is an open embedding \( j : \bar{V} \hookrightarrow \bar{V} \) with dense image of a \( \bar{K} \)-variety \( \bar{V} \) into a reduced proper flat \( O_{\bar{K}} \)-scheme \( \bar{V} \). A connected \((V, \bar{V})\) is said to be semi-stable, a.k.a. ss-pair, if there exists an ss-pair \((U, \bar{U})\) over \( K \) and a \( \bar{K} \)-point \( \alpha : K_\bar{K} \to \bar{K} \) (see (b)) such that \((V, \bar{V})\) is isomorphic to \((U, \bar{U})_\alpha = (U_\bar{K}, \bar{U}_{O_{K_\bar{K}}}) := (U \otimes_{O_{K_\bar{K}}} \bar{K}, \bar{U} \otimes_{O_{K_\bar{K}}} \bar{O}_{\bar{K}}) \). Then \( \bar{V} \) is normal (say, by Serre’s criterion). An arbitrary \((V, \bar{V})\) is semi-stable if such are all its connected
components. Denote by $\mathcal{V}ar_{\bar{K}}^{\text{ss}}$ the category of all arithmetic pairs over $\bar{K}$, and by $\mathcal{V}ar_{K}^{\text{ss}} = \mathcal{V}ar_{\bar{K}/K}^{\text{ss}}$, its full subcategory of ss-pairs.

**Remark.** If $K'$ is a finite extension of $K$ contained in $\bar{K}$, then $\mathcal{V}ar_{K'/K}^{\text{ss}} \subset \mathcal{V}ar_{\bar{K}/K}^{\text{ss}}$. For all the constructions below the difference between them is irrelevant.

These categories are connected by commutative diagrams of functors

$$
\begin{aligned}
\mathcal{V}ar_{\bar{K}}^{\text{ss}} & \rightarrow \mathcal{V}ar_{\bar{K}}^{\text{nc}} \rightarrow \mathcal{V}ar_{\bar{K}}, & \mathcal{V}ar_{\bar{K}}^{\text{ss}} & \rightarrow \mathcal{V}ar_{\bar{K}}^{\text{nc}} \rightarrow \mathcal{V}ar_{\bar{K}}, \\
\uparrow & & \uparrow & \uparrow \\
\mathcal{V}ar_{K}^{\text{ss}} & \rightarrow \mathcal{V}ar_{K}^{\text{nc}} \rightarrow \mathcal{V}ar_{K}, & \mathcal{V}ar_{K}^{\text{ss}} & \rightarrow \mathcal{V}ar_{K}^{\text{nc}} \rightarrow \mathcal{V}ar_{K},
\end{aligned}
$$

(2.2.1)

where the vertical arrows are the fully faithful embeddings, and the upper horizontal lines are faithful forgetful functors of passing to the generic fiber and $(U, \bar{U}) \mapsto U$. The $K$- and $\bar{K}$-settings are connected by base change functors

$$
\begin{aligned}
\mathcal{V}ar_{\bar{K}}^{\text{ss}} & \rightarrow \mathcal{V}ar_{K}^{\text{nc}} \rightarrow \mathcal{V}ar_{K}, & \mathcal{V}ar_{\bar{K}}^{\text{ss}} & \rightarrow \mathcal{V}ar_{K}^{\text{nc}} \rightarrow \mathcal{V}ar_{K}, \\
\uparrow & & \uparrow & \uparrow \\
\mathcal{V}ar_{\bar{K}}^{\text{ss}} & \rightarrow \mathcal{V}ar_{\bar{K}}^{\text{nc}} \rightarrow \mathcal{V}ar_{\bar{K}}.
\end{aligned}
$$

Here the two right vertical arrows are the evident base change $\otimes_{K} \bar{K}$, and the left one assigns to a semi-stable $K$-pair $(U, \bar{U})$ the disjoint sum of pairs $(U, \bar{U})_{\alpha}$ for all $\bar{K}$-points $\alpha : K_{\bar{U}} \rightarrow \bar{K}$.

2.3. A morphism $f : (V, \bar{V}) \rightarrow (U, \bar{U})$ of pairs in either of the settings of §2.2 is called an alteration (of $(U, \bar{U})$) if $f^{-1}(U) = V$, the generic fibers of $f$ are zero-dimensional, and their union is dense in $V$. In setting (a), $f$ is a (strict) nc-alteration if $(V, \bar{V})$ is a (strict) nc-pair; in settings (b), (c), $f$ is a (strict) ss-alteration if $(V, \bar{V})$ is a (strict) ss-pair.

If $f$ is an alteration, then $f|_{V} : V \rightarrow U$ is proper and surjective; the composition of alterations is an alteration.

Here is a key result of de Jong [dJ1, 4.1, 6.5]:

**Theorem.** Every geometric pair admits a strict nc-alteration. Every arithmetic pair, either over $K$ or over $\bar{K}$, admits a strict ss-alteration. The alterations can be chosen so that $\bar{V}$ is projective.

**Remark.** Our conventions slightly differ from de Jong’s: he understands varieties to be irreducible and semi-stable $K$-pairs $(U, \bar{U})$ to have property $K_{\bar{U}} = K$; his notation for $(U, \bar{U})$ is $(U, \bar{Z})$, $Z := \bar{U} \setminus U$.

2.4. For a field $K$, the $h$-topology (see [SV]) on $\mathcal{V}ar_{K}$ is generated by the pretopology whose coverings are finite families of maps $\{Y_{\alpha} \rightarrow X\}$ such that $Y := \amalg Y_{\alpha} \rightarrow X$ is a universal topological epimorphism. It is stronger than the étale and proper topologies. We denote the $h$-site of $\mathcal{V}ar_{K,h}$; the $h$-site of $X$ is denoted by $X_{h}$.

**Exercise.** Let $f : Y \rightarrow X$ be a morphism in $\mathcal{V}ar_{K}$.

(i) $f$ is an h-covering if (and only if) for every irreducible curve $C \subset X$ the base change $Y_{\bar{C}} \rightarrow \bar{C}$, where $\bar{C}$ is the normalization of $C$, is an h-covering.

---

8This means that a subset of $X$ is Zariski open if (and only if) its preimage in $Y$ is open, and the same is true after any base change.

9The latter is generated by a pretopology whose coverings are proper surjective maps.

10Hint: For an open $V \subset Y$, its image in $X$ is constructible (EGA IV 1.8.4), so to show that $f(V)$ is open it suffices to check that for any curve $C \subset X$ the intersection $C \cap f(V)$ is open in $C$. 

---

License or copyright restrictions may apply to redistribution; see http://www.ams.org/journal-terms-of-use
(ii) If $X$ is a regular curve, then $f$ is an h-covering if (and only if) the closure of the generic fiber of $f$ maps onto $X$, or, equivalently, $f$ is a covering for the flat topology.

**Remark.** By [SV, 10.4], every h-covering is a Zariski covering locally in proper topology. Therefore (see [D], [SD], or [Con]) h-coverings are morphisms of universal cohomological descent for torsion étale sheaves; if $K = \mathbb{C}$, then h-coverings are morphisms of universal cohomological descent for arbitrary sheaves on the classical topology. In particular, for any h-hypercovering $Y$ of $X$ and an abelian group $A$ the canonical map $R\Gamma(X_{\text{ét}}, A) \to R\Gamma(Y_{\text{ét}}, A)$ (:= the total complex of the cosimplicial system of complexes $R\Gamma(Y_{i\text{ét}}, A)$) is a quasi-isomorphism if $A$ is a torsion group. Passing to the limit, we see that $R\Gamma_{\text{ét}}(X, \mathbb{Z}_p) \simeq R\Gamma_{\text{ét}}(Y, \mathbb{Z}_p)$. If $K = \mathbb{C}$, then $R\Gamma(X_{\text{cl}}, A) \simeq R\Gamma(Y_{\text{cl}}, A)$ for any $A$. Since h-topology is stronger than the étale one, we see that $R\Gamma(X_{\text{ét}}, A) \simeq R\Gamma(X, A)$ if $A$ is a torsion group (see [SV], 10.7 for a direct proof).

2.5. Let $\phi$ be the forgetful functor $(U, \bar{U}) \to U$ on any of the categories $\mathcal{V}ar^2$ in \S 2.2.

**Proposition.** If $\mathcal{V}ar^2$ is either of the categories $\mathcal{V}ar_K^c$, $\mathcal{V}ar_K^{nc}$, $\mathcal{V}ar_K^{cc}$, $\mathcal{V}ar_K^{ss}$, then $(\mathcal{V}ar^2, \phi)$ is a base for $\mathcal{V}ar_{K^h}$. If $\mathcal{V}ar^2$ is $\mathcal{V}ar_K^{cc}$ or $\mathcal{V}ar_K^{ss}$, then $(\mathcal{V}ar^2, \phi)$ is a base for $\mathcal{V}ar_{K^h}$.

**Proof.** We consider the arithmetic $K$-setting, leaving the other two settings for the reader. Let us show that $(\mathcal{V}ar_K^{cc}, \phi)$ satisfies condition $(\star)$ from \S 2.1. Our datum is a $K$-variety $V$ and a finite collection of arithmetic $K$-pairs $(U_\alpha, \bar{U}_\alpha)$ and maps $f_\alpha : V \to U_\alpha$. We need to find an h-covering $\pi : V' \to V$ and an arithmetic pair $(V', \bar{V}')$ such that $f_\alpha \pi$ extend to maps $(V', \bar{V}') \to (U_\alpha, \bar{U}_\alpha)$. First we find an h-covering $V' \to V$ such that $V'$ sits in some arithmetic $K$-pair $(V', \bar{V}')$; let $V'/V$ be a quasi-projective modification of $V$ provided by the Chow lemma, and take for $\bar{V}'$ the closure of $V'$ in a projective space. Then take $\bar{V}'$ to be the closure of the image of $V'$ by the embedding $V' \hookrightarrow \bar{V}' \times \Pi \bar{U}_\alpha$, and we are done.

To show that $(\mathcal{V}ar_{K}^{ss}, \phi)$ is a base for $\mathcal{V}ar_{K^h}$, it suffices to check that $(\mathcal{V}ar_{K}^{ss}, \iota)$, where $\iota$ is the embedding $\mathcal{V}ar_{K}^{ss} \hookrightarrow \mathcal{V}ar_{K}^{cc}$, is a base for the $\phi$-induced topology on $\mathcal{V}ar_{K}^{cc}$ (see Exercise (ii) in \S 2.1). Since $\iota$ is fully faithful, it suffices to check that for every $(U, \bar{U}) \in \mathcal{V}ar_{K}^{cc}$ there exists a map $(U', \bar{U}') \to (U, \bar{U})$ such that $U' \to U$ is an h-covering and $(U', \bar{U}')$ is semi-stable. Such a datum is provided by the de Jong theorem in \S 2.3, and we are done.

We call the $\phi$-induced topology on either of the categories $\mathcal{V}ar^2$ the h-topology.

**Remarks.** (i) Any h-covering of $(U, \bar{U}) \in \mathcal{V}ar_{K}^{ss}$ has a refinement with terms of the same dimension as $U$ (indeed, the same assertion in $\mathcal{V}ar_K$ is true by [SV, 10.4]; to pass to $\mathcal{V}ar_{K}^{ss}$, we apply the constructions from the proof above, and they preserve the dimension).

(ii) The proposition remains true if we replace the category of ss- or nc-pairs by its subcategory of strict pairs $(U, \bar{U})$ with projective $U$.

(iii) For any functor in (2.2.1) its source is a base for the h-topology of the target, and the induced topology on the source is the h-topology.

(iv) The functors in (2.2.2) are continuous for the h-topologies.

\[\text{In fact, every } V \text{ sits in a } K\text{-pair due to Nagata's theorem.}\]
2.6. By §2.1 and §2.5, \( \phi \) identifies h-sheaves on \( \text{Var}_K \), resp. \( \text{Var}_K^\infty \), with h-sheaves on \( \text{Var}_K^\infty \), \( \text{Var}_K^\infty \), \( \text{Var}_K^{\infty} \), resp. \( \text{Var}_K^{\infty} \), \( \text{Var}_K^{\infty} \). Thus we have the h-localization functors

\[
\mathcal{P}Sh(\text{Var}_K^\infty) \to \text{Var}_K^{\infty}, \quad \mathcal{P}Sh(\text{Var}_K^\infty) \to \text{Var}_K^{\infty}
\]

which assign to any presheaf \( \mathcal{F} \) on pairs the corresponding h-sheaf \( \mathcal{F}^{\infty} \) viewed as an h-sheaf on varieties.

Remark. For any presheaf on \( \text{Var}_K^\infty \), \( \text{Var}_K^{\infty} \) or \( \text{Var}_K^{\infty} \), its h-sheafification coincides with h-sheafification of its restriction to resp. \( \text{Var}_K^{\infty} \), \( \text{Var}_K^{\infty} \) or \( \text{Var}_K^{\infty} \). For a presheaf on \( \text{Var}_K^{\infty} \), its h-sheafification is the same as h-sheafification of its restriction to \( \text{Var}_K^{\infty} \), where \( K' \subset K \) is any finite extension of \( K \) (see Remark in §2.2).

3. The \( p \)-adic period map

3.1. The derived de Rham algebra in logarithmic setting. We refer to [K1] for log scheme basics. There are two (in general, nonequivalent) ways to define the cotangent complex for log schemes due, respectively, to Gabber and Olsson; see [Ol] for Gabber’s approach ([Ol] §8) is more direct and precise.

For a commutative ring \( A \), a prelog structure on \( A \) is a homomorphism of monoids \( \alpha : L \to A \), where \( L \) is a commutative integral monoid (written multiplicatively) and \( A \) is viewed as a monoid with respect to the product. Rings equipped with prelog structures form a category in an evident way; denote its objects simply by \( A,L \).

Let \( \Omega_{B/A} \) be the category of morphisms \( (A,L) \to (B,M) \); we denote such an object by \( (B,M)/(A,L) \). Let \( \Omega_{(B,M)/(A,L)} \) be the \( B \)-module of relative Kähler log differentials: it is generated by \( \Omega_{B/A} \), elements \( \log d \), \( d \in M \), subject to relations \( \log m_1 m_2 = \log m_1 + \log m_2, \alpha(m) \log m = \alpha(m) \), and \( \log m = 0 \) if \( m \) is in the image of \( L \). The de Rham dg algebra of relative log forms \( \Omega_{(B,M)/(A,L)} \) has components \( \Omega^n_{(B,M)/(A,L)} := \Lambda^*_{B/A} \Omega_{B/A}(B,M)/(A,L) \); elements \( \log d \) are degree 1 cycles. It carries the Hodge filtration \( F^n = \Omega^n_{(B,M)/(A,L)} \).

A pair of sets \( I,J \) yields a free object \( P_{(A,L)}(I,J) \) in \( \mathcal{C}_{(A,L)} \): the corresponding ring is a polynomial algebra \( A[t_i,t_j]_{i \in I,j \in J} \), the monoid is \( L \oplus \mathbb{N}[I] \), where \( \mathbb{N}[I] \) is the free monoid generated by \( I \), and the structure map sends the generator \( m_i \) of \( \mathbb{N}[I] \), \( i \in I \), to \( t_i \). The de Rham algebra \( \Omega_{P_{(A,L)}(I,J)/(A,L)} \) is freely generated, as a graded commutative \( A \)-algebra, by elements \( t_i, t_j \) of degree \( 0 \) and \( d \log t_i := d \log m_i, dt_j \) of degree 1, where \( i \in I \), \( j \in J \).

Every \( (B,M)/(A,L) \in \mathcal{C}_{(A,L)} \) admits a canonical simplicial resolution \( P = P_{(A,L)}(B,M) \). This is a simplicial object of \( \mathcal{C}_{(A,L)} \) augmented over the object \( (B,M)/(A,L) \) and such that every \( P_i \) is a free object as above. Thus we have the simplicial dg algebra \( \Omega_{P_{/(A,L)}} \) filtered by the Hodge filtration \( F \). Denote by \( L\Omega_{(B,M)/(A,L)} \) the corresponding total complex, \( L\Omega^n_{(B,M)/(A,L)} = \bigoplus_i (-i)^* \Omega^n_{i/(A,L)} \); this is a filtered commutative dg algebra. Let \( L\Omega_{(B,M)/(A,L)} \) be its \( F \)-completion; as in §1.2, we understand it as a mere projective system of quotients \( L\Omega^n_{(B,M)/(A,L)}/F^n \).

One has a natural quasi-isomorphism of graded dg algebras \( \text{gr}^n_F L\Omega_{(B,M)/(A,L)} \to (LA^n_{B/M}(L_{(B,M)/(A,L)})^)[-n] \). Here \( L_{(B,M)/(A,L)} := \Omega_{P_{/(A,L)}} \otimes_{P_{(B,M)}} B \) is the relative

---

\[\text{In all situations that we will consider, the two versions coincide by [Ol] 8.34.}\]

\[\text{It produces a true complex, while Olsson’s construction yields a mere compatible datum of the canonical filtration truncations.}\]
log cotangent complex; it is acyclic in positive degrees, and \(H^0 L_{(B,M)/(A,L)} = \Omega^1_{(B,M)/(A,L)}\). The constructions are compatible with direct limits. If in the above definition we replace \(P\) by any free simplicial resolution of \((B,M)/(A,L)\), then the output is naturally quasi-isomorphic to \(L\Omega^1_{(B,M)/(A,L)}\). The plain cotangent complex and derived de Rham algebra for \(B/A\) map naturally to logarithmic ones.

For any map \((X,M) \to (S,L)\) of integral log schemes, the above constructions, being \(\acute{e}tale\) sheafified, yields the log cotangent complex \(L_{(X,M)/(S,L)}\), the derived log de Rham algebra \(L\Omega^1_{(X,M)/(S,L)}\), and its \(F\)-completion \(L\Omega^1_{(X,M)/(S,L)}\), which are complexes of sheaves on \(X_{\acute{e}t}\). We use only the completed complex \(L\Omega^1\).

3.2. Let \((U,\hat{U})\) be a pair as in \(\S 2.2\). We view \(\hat{U}\) as a log scheme with the usual integral log structure \(\mathcal{O}_U \cap j_! \mathcal{O}_U^\wedge \to \mathcal{O}_U\); by abuse of notation, let us denote this log scheme again by \((U,\hat{U})\). Any morphism of pairs \((U,\hat{U}) \to (V,V)\) is a morphism of log schemes, so we have the relative log cotangent complex \(L_{(U,\hat{U})/(V,V)}\), the derived log de Rham algebra \(L\Omega^1_{(U,\hat{U})/(V,V)}\), etc., as above. There is a canonical morphism \(L\Omega^1_{U/V} \to L\Omega^1_{(U,\hat{U})/(V,V)}\). We also have “absolute” complexes: in the arithmetic \(K\)-setting, these are \(L_{(U,\hat{U})} := L_{(U,\hat{U})/O_K}\), \(L\Omega^1_{(U,\hat{U})/O_K}\), where \(O_K\) is considered with the trivial log structure \(O_K\); for the geometric \(K\)- or \(\hat{K}\)-setting, replace \(O_K\) by \(K\), resp. \(\hat{K}\).

Remark. For \((V,\hat{V}) \in \mathcal{V}\) one has \(L\Omega^1_{(\hat{V},V)} \simeq \Omega^1_{(V,V)}\). Hence for \((U,\hat{U}) \in \mathcal{V}\) one has \(R\Gamma(U, L\Omega^1_{(U,\hat{U})}) \otimes \mathbb{Q} \simeq R\Gamma(U, \Omega^1_{(U,\hat{U})})\). Ditto for pairs over \(K\).

Consider now the arithmetic \(\hat{K}\)-pair \(\text{Spec}(\hat{K},O_{\hat{K}}) := (\text{Spec} \hat{K}, \text{Spec} O_{\hat{K}})\):

**Lemma.** The cotangent complex \(L_{(K,O_K)}\) is acyclic in nonzero degrees, and the canonical map \(\Omega_{O_K} \to \Omega_{(K,O_K)} := H^0 L_{(K,O_K)}\) is an isomorphism. Therefore the canonical map \(A_{\text{dR}} := L\Omega^1_{\hat{K}} \to L\Omega^1_{(K,O_K)}\) is a filtered quasi-isomorphism.

**Proof.** For a finite extension \(K'\) of \(K\) consider the log scheme \(\text{Spec}(K',O_{K'}) := (\text{Spec} K', \text{Spec} O_{K'})\). It is a log complete intersection over \(O_K\) (see [Ol], 6.8). If \(\pi\) is a generator of \(O_{K'}/O_K\), \(f(t)\) its minimal polynomial, then, by [Ol] 6.9, \(L_{(K',O_{K'})}\) is quasi-isomorphic to the cone of the multiplication by \(f'(\pi)\) map \(O_{K'} \to O_{K'} \cdot \mathfrak{m}_{K'}^{-1}\). Thus \(L_{(K',O_{K'})}\) is acyclic in nonzero degrees, \(\Omega_{(K',O_{K'})} := H^0 L_{(K',O_{K'})}\), a cyclic \(O_{K'}\)-module, and the canonical map \(\Omega_{O_{K'}} \to \Omega_{(K',O_{K'})}\) is an embedding with cokernel isomorphic to the residue field \(O_{K'}/\mathfrak{m}_{K'}\). Now pass to the inductive limit, and use the fact that \(\Omega_{O_K}\) is \(p\)-divisible (see \(\S 1.3\)).

3.3. Consider the presheaf \((U,\hat{U}) \to R\Gamma_{\text{dR}}^3(U,\hat{U}) := R\Gamma(U, L\Omega^1_{(U,\hat{U})})\) of filtered \(E_\infty\) dg \(O_K\)-algebras on \(\mathcal{V}\). Denote by \(A^3_{\text{dR}}\) its h-sheafification (2.6.1); this is an h-sheaf of filtered \(E_\infty\) \(O_K\)-algebras on \(\mathcal{V}\) (as above, we see it as the projective system of quotients modulo \(F^t\)). Since \(A_{\text{dR}} = A^3_{\text{dR}}(\text{Spec} \hat{K})\) by Lemma in \(\S 3.2\), \(A_{\text{dR}}\), viewed as a constant filtered h-sheaf, maps into \(A^3_{\text{dR}}\).

**Theorem** (\(p\)-adic Poincaré lemma). The maps \(A_{\text{dR}} \otimes^L \mathbb{Z}/p^n \to A^3_{\text{dR}} \otimes^L \mathbb{Z}/p^n\) are filtered quasi-isomorphisms of h-sheaves on \(\mathcal{V}\).

For a proof, see \(\S 4\). Assuming it, let us define the \(p\)-adic period map \(\rho\).
3.4. The Hodge-Deligne filtration. For this subsection, \( K \) is any field of characteristic 0. Consider the presheaf \( (V, \tilde{V}) \to R\Gamma_{\text{dr}}(V, \tilde{V}) := R\Gamma(V, \Omega_{(V, \tilde{V})}^P) \) of filtered \( E_\infty \)-\( K \)-algebras on \( \text{Var}_{\text{nc}}^\sharp K \). Let \( A_{\text{dr}} \) be its h-sheafification \( (2.6.1) \), which is an h-sheaf of filtered \( E_\infty \)-\( K \)-algebras on \( \text{Var}_K \) (viewed as the projective system of quotients modulo \( F^j \)). For any \( X \in \text{Var}_K \) set
\[
R\Gamma_{\text{dr}}(X) := R\Gamma(X, A_{\text{dr}}).
\]
This is Deligne’s de Rham complex of \( X \) equipped with Deligne’s Hodge filtration.

Proposition. (i) For \( (V, \tilde{V}) \in \text{Var}_{\text{nc}}^\sharp K \) the canonical map \( R\Gamma_{\text{dr}}(V, \tilde{V}) \to R\Gamma_{\text{dr}}(V) \) is a filtered quasi-isomorphism.

(ii) The differential of \( R\Gamma_{\text{dr}}(X) \) is strictly compatible with the filtration. \( H^i_{\text{dr}}(X) := H^i R\Gamma_{\text{dr}}(X) \) are \( K \)-vector spaces of dimension equal to \( \dim H^i(\Omega_K^p, \mathbb{Q}_p) \).

(iii) For any smooth variety \( X \) there is a canonical (nonfiltered) quasi-isomorphism \( R\Gamma(X, \Omega_X) \to R\Gamma_{\text{dr}}(X) \).

Proof. By Lefschetz’s principle, we can assume that \( K = \mathbb{C} \). For \( (V, \tilde{V}) \in \text{Var}_{\text{nc}}^\sharp K \) the maps \( R\Gamma_{\text{dr}}(V, \tilde{V}) \to R\Gamma_{\text{dr}}(V, \Omega_{(V, \tilde{V})}) \to R\Gamma(V, \Omega^\wedge_{\text{dr}}) \) are quasi-isomorphisms by \([Gr]\). Thus for any h-hypercovering \( \{Y, \tilde{Y}\}/X \) of \( X \in \text{Var}_{\text{nc}}^\sharp K \) the cohomological descent (see Remark in §2.4) yields a canonical quasi-isomorphism \( R\Gamma(Y, \Omega^\wedge_{\text{dr}}) \to R\Gamma(\text{cl}, \Omega^\wedge_{\text{dr}}) \). If we equip \( R\Gamma(\text{cl}, \mathbb{C}) \) with the Hodge-Deligne filtration of mixed Hodge theory \([D]\), then this is a filtered quasi-isomorphism. Therefore we have a canonical filtered quasi-isomorphism \( R\Gamma_{\text{dr}}(X) \cong R\Gamma(\text{cl}, \mathbb{C}) \). Now (i) and the second assertion of (ii) are clear; the first assertion of (ii) follows from mixed Hodge theory. The quasi-isomorphism in (iii) is \( R\Gamma(X, \Omega_X) \cong R\Gamma(Y, \Omega_Y) \cong R\Gamma(Y, \Omega^\wedge_{\text{dr}}) \), where the arrows are quasi-isomorphisms by the cohomological descent (since \( R\Gamma(Y, \Omega^\wedge_Y) \to R\Gamma(X, \Omega^\wedge_Y) \)).

3.5. We return to the setting of §3.3, so \( K \) is our \( p \)-adic field. Let \( X \) be any variety over \( K \). It yields a filtered \( E_\infty \)-\( O_K \)-algebra
\[
R\Gamma_{\text{dr}}^g(X) := R\Gamma(X, A_{\text{dr}}).
\]
Since \( A_{\text{dr}} \otimes \mathbb{Q} = \hat{K} \) (see Remark (i) in §1.5), \( R\Gamma_{\text{dr}}^g(X) \otimes \mathbb{Q} \) is a \( \hat{K} \)-algebra. By Remark in §3.2, we have a filtered quasi-isomorphism of \( E_\infty \)-\( K \)-algebras
\[
R\Gamma_{\text{dr}}^g(X) \otimes \mathbb{Q} \cong R\Gamma_{\text{dr}}(X).
\]

Let us compute \( R\Gamma_{\text{dr}}^g(X) \otimes \mathbb{Z}_p \). Consider the morphisms of filtered complexes \( R\Gamma(X_{et}, \mathbb{Z}) \otimes^L A_{\text{dr}} \to R\Gamma(X_{et}, A_{\text{dr}}) \to R\Gamma(X, A_{\text{dr}}) \to R\Gamma(X, A_{\text{dr}}) = R\Gamma_{\text{dr}}^g(X) \). After applying \( \cdot \otimes^L \mathbb{Z}_p/p^n \), the arrows become filtered quasi-isomorphisms (the first one by Remark in §2.4, the second one by the Poincaré lemma in §3.3), so we get a filtered quasi-isomorphism \( R\Gamma(X_{et}, \mathbb{Z}/p^n) \otimes^L A_{\text{dr}} \to R\Gamma_{\text{dr}}^g(X) \otimes^L \mathbb{Z}/p^n \). Since \( R\Gamma_{et}(X, \mathbb{Z}_p) = \lim_{\text{proj}} R\Gamma(X_{et}, \mathbb{Z}/p^n) \) is the perfect \( \mathbb{Z}_p \)-complex and \( R\Gamma(X_{et}, \mathbb{Z}/p^n) = R\Gamma(X_{et}, \mathbb{Z}) \otimes^L \mathbb{Z}/p^n \), one has, passing to the homotopy limit as in §1.1, \( R\Gamma_{et}(X, \mathbb{Z}_p) \otimes^L \mathbb{Z}_p \otimes^L \mathbb{Z}_p \to R\Gamma_{dr}^g(X) \otimes \mathbb{Z}_p \). Tensoring by \( \mathbb{Q} \), we get a filtered quasi-isomorphism of filtered \( E_\infty \)-\( \mathbb{B}^+_{\text{dr}} \)-algebras (see (1.5.1))
\[
\beta : R\Gamma_{et}(X, \mathbb{Q}_p) \otimes \mathbb{B}^+_{\text{dr}} \to R\Gamma_{\text{dr}}^g(X) \otimes \mathbb{Q}_p.
\]
\[\text{\footnote{Here we view } \text{X as an h-sheaf on } \text{Var}_{\text{nc}}^\sharp K, \text{ so } (Y, \tilde{Y}) \text{ is a simplicial object of } \text{Var}_{\text{nc}}^\sharp K \text{ equipped with an augmentation map } Y \to X \text{ that makes } Y \text{ an h-hypercovering of } X.}\]
Let $\alpha : R_G^d(X) \otimes K B^+_G \to R_G^d(X) \otimes \mathbb{Q}_p$ be the $B^+_G$-linear extension of the composition $R_G^d(X) \otimes \mathbb{Q}_p 	o R_G^d(X) \otimes \mathbb{Q}_p$, where the first arrow is inverse to (3.5.2) and the second one comes from the canonical map $\tilde{\Omega} \to ? \otimes \mathbb{Z}_p$. We get a morphism of filtered $E_\infty B^+_G$-algebras

$$\rho = \rho_G := \beta^{-1} \alpha : R_G^d(X) \otimes K B^+_G \to R_G(\tilde{X}, \mathbb{Q}_p) \otimes \mathbb{Q}_p B^+_G.$$  

Remarks. (i) The Galois group $\text{Gal}(K/K)$ acts on $\text{Var}_K$ and on both sides of (3.5.4) by transport of structure, and $\rho^+$ is evidently compatible with this action.

In particular, if $X$ is defined over $K$, i.e., $X = X_K \otimes K$, then $R_G^d(X) = R_G^d(X_K) \otimes K$, and we can rewrite (3.5.4) as a $\text{Gal}(K/K)$-equivariant morphism

$$\rho : R_G^d(X_K) \otimes K B^+_G \to R_G(\tilde{X}, \mathbb{Q}_p) \otimes \mathbb{Q}_p B^+_G.$$  

(ii) The map $\rho$ does not change if we replace $K$ by any of its finite extensions that are contained in $K$ (see Remark in §2.6).

3.6. Theorem. The $B^+_G$-linear extension of $\rho$ is a filtered quasi-isomorphism: for any $X \in \text{Var}_K$ one has

$$\rho : R_G^d(X) \otimes K B^+_G \to R_G(\tilde{X}, \mathbb{Q}_p) \otimes \mathbb{Q}_p B^+_G.$$  

Proof. (a) The case of $X = G_m = G_{m,K}$: The $\tilde{K}$-line $H^1_{dR}(G_m) = \text{gr}^1_H^d(\hat{G}_m)$ is generated by $d \log t$. The $\mathbb{Z}_p$-line $H^1_{dR}(G_m, \mathbb{Z}_p)(1)$ is generated by the class $c(t)$ of the Kummer $\mathbb{Z}_p(1)$-torsor $t = \lim_{\leftarrow} t_n$, $t_n := (t^{1/p^n})$. Due to the canonical identification $\mathbb{C}_p(1) \to m^1_{dR}/\mathbb{Z}_p^1 = \text{gr}^1_F B^+_G$, see §1.4, §1.5, we can view $c(t)$ as a generator of the $\mathbb{C}_p$-line $H^1_{dR}(G_m, \mathbb{Q}_p) \otimes \text{gr}^1_F B^+_G$.

Lemma. One has $\text{gr}^1_F(\rho)(d \log t) = c(t) \in H^1_{dR}(G_m, \mathbb{Q}_p) \otimes \text{gr}^1_F B^+_G$.

Proof of Lemma. We make a mod $p^n$ computation. Consider the ss-pair $(G_m, \hat{G}_m)$, $\hat{G}_m := \mathbb{P}^1_{\mathbb{Q}_p}$. One has $\text{gr}^1_F \Omega^1(\hat{G}_m, \hat{G}_m) = \Omega^1_{\hat{G}_m, \hat{G}_m}[-1]$, so $\text{gr}^1_F \log t \in \Omega^1_{\hat{G}_m, \hat{G}_m}$. As in §1.1, let $C_n := \text{Cone}(\mathbb{C}^0 : \mathbb{Z} \to \mathbb{Z})$. Let $d \log c(t_n)$ be the image of the class $c(t_n)$ of the covering $H^1_{\text{dR}}(G_m, \mu_{p^n})$ to $H^1_{\text{dR}}(G_m, \mathbb{Z}_p) \otimes C_n$, where the first arrow comes from the coefficient maps $\mu_{p^n} \to \Omega_{K, p^n} \to \Omega_{K,-1} \otimes C_n = \text{gr}^1_F \Omega_{k, \mu_{p^n}} \otimes C_n$. To prove the lemma, we will show that the image of $d \log t$ by the embedding

$$\text{gr}^1_F R_G_{dR}^d(G_m) \to \text{gr}^1_F R_G_{dR}^d(G_m) \otimes C_n$$

is homologous to $d \log c(t_n)$.

Let $\mathbb{G}_m$ be a copy of $G_m$ with parameter $t$, and $\pi : \mathbb{G}_m \to G_m$ be the projection $t = \tilde{t}^{p^n}$. Thus $\mathbb{G}_m/\mathbb{G}_m$ is our $\mu_{p^n}$-torsor $t_n$, so $c(t_n)$ is represented by a Čech $\mu_{p^n}$-cocycle $c(t_n)$ for the étale covering $\mathbb{G}_m/\mathbb{G}_m$. The corresponding Čech hypercovering is the twist of $\mathbb{G}_m$ by the universal $\mu_{p^n}$-torsor $t_n$ over the classifying simplicial space $B_{\mu_{p^n}}$, so for any sheaf $\mathcal{F}$ the Čech complex of $\mathbb{G}_m/\mathbb{G}_m$ with coefficients in $\mathcal{F}$ is the cochain complex $C(\mu_{p^n}, \Gamma(\mathbb{G}_m, \mathcal{F}))$ acting on sections by the translations. The 1-cocycle $c(t_n)$ is the identity map $\mu_{p^n} \to \mu_{p^n} = \Gamma(\mathbb{G}_m, \mu_{p^n})$.

Our $\pi$ extends to the h-covering of semi-stable pairs $(\mathbb{G}_m, \mathbb{G}_m) \to (G_m, \hat{G}_m)$, and the Čech hypercovering extends to a hypercovering in $\text{Var}_K$ which is the $t_n$-twist of $(\mathbb{G}_m, \hat{G}_m)$. So one has a canonical map $C(\mu_{p^n}, \Gamma(\hat{G}_m, \Omega^1_{\hat{G}_m, \hat{G}_m})[-1]) \to \text{gr}^1_F R_G_{dR}^d(G_m)$; hence $C(\mu_{p^n}, \Gamma(\mathbb{G}_m, \Omega^1_{\mathbb{G}_m, \mathbb{G}_m})[-1]) \otimes C_n \to \text{gr}^1_F R_G_{dR}^d(G_m) \otimes C_n$.

Both $d \log t$ and $d \log c(t_n)$ are 1-cocycles in $C(\mu_{p^n}, \Gamma(\mathbb{G}_m, \Omega^1_{\mathbb{G}_m, \mathbb{G}_m})[-1]) \otimes C_n$: namely, $d \log t \in C^0(\mu_{p^n}, \Gamma(\mathbb{G}_m, \Omega^1_{\mathbb{G}_m, \mathbb{G}_m})[-1])$ and $d \log c(t_n) \in C^1(\mu_{p^n}, \Omega_{K, p^n})$. 

License or copyright restrictions may apply to redistribution; see http://www.ams.org/journal-terms-of-use
⊂ C^1(μ_p^n, Γ(˘G_m, Ω^1_{(˘G_m, G_m)}))[-1] ⊗ C_n). Their difference is the differential of the 0-cochain \( d \log \ell \in C^0(μ_p^n, Γ(˘G_m, Ω^1_{(˘G_m, G_m)})) \). Indeed, it yields the Gysin isomorphisms \( \iota_{\text{ét}} : R\Gamma_{\text{dR}}(Y) \xrightarrow{\sim} R\Gamma_{\text{dR}}(X)(1)[2] := \text{Cone}(R\Gamma_{\text{dR}}(X) \to \Gamma_{\text{dR}}(X \setminus Y))(1)[1], \iota_{\text{ét}, Q_p} : R\Gamma_{\text{ét}}(Y, Q_p) \xrightarrow{\sim} R\Gamma_{\text{ét}}(X, Q_p)(1)[2]. \) Let us show that \( \rho \) commutes with the Gysin maps.

Consider the deformation to the normal cone diagram

\[
\begin{array}{c}
\mathcal{L} \hookrightarrow X_{\mathbb{A}^1} \hookrightarrow X \\
\uparrow \quad \uparrow \quad \uparrow \\
Y \hookrightarrow Y_{\mathbb{A}^1} \hookrightarrow Y.
\end{array}
\]

Here \( Y_{\mathbb{A}^1} = \mathbb{A} \times \mathbb{A}^1 \) is the zero section of the normal bundle \( \mathcal{L} \) over \( Y \) and the bottom embeddings are \( y \mapsto (y, 0), (y, 1) \). It yields a commutative diagram of the de Rham cohomology

\[
\begin{array}{cccc}
R\Gamma_{\text{dR}}(\mathcal{L})(1)[2] & \xleftarrow{\iota_{\text{ét}, Y}(X_{\mathbb{A}^1})(1)[2]} & R\Gamma_{\text{dR}}(X)(1)[2] \\
\uparrow & \uparrow & \uparrow \\
R\Gamma_{\text{dR}}(Y) & \xrightarrow{\sim} & R\Gamma_{\text{dR}}(Y_{\mathbb{A}^1}) & \to R\Gamma_{\text{dR}}(Y),
\end{array}
\]

where the vertical arrows are the Gysin isomorphisms and the horizontal ones are pullbacks. There is a similar diagram for the \( \mathbb{Q}_p \)-cohomology. The horizontal maps are filtered quasi-isomorphisms, so, since \( \rho \) is compatible with pullbacks, we see that the Gysin compatibility for \( Y \hookrightarrow X \) amounts to one for \( Y \hookrightarrow \mathcal{L} \).

So we can assume that \( X \) is a line bundle \( \mathcal{L} \) over \( Y \) and \( i \) its zero section. Now the source of both \( i_\ast \)'s are dg algebras, the targets are modules over them (due to the projection \( X \to Y \)), and \( i_\ast \)'s are morphisms of modules. Thus it suffices to check that \( \rho \) identifies the images of \( 1 \). The assertion is local with respect to \( Y \); hence we can assume that \( Y \) is trivial. By base change, we reduced to the case when \( Y \) is a point, where we are done by (a).

(c) The case of a smooth projective \( X \): Let us check that the morphism of bigraded rings \( \text{gr}_F^p H_{\text{ét}}^\ast(X) \otimes \mathcal{O} \to H_{\text{ét}}^\ast(X, \mathbb{Q}_p) \otimes \mathcal{O} \) is an isomorphism. It is an isomorphism for \( * = 0 \). By (b), \( \text{gr}_F^p \mathcal{O} \) is acyclic and identifies the classes of a hyperplane section. Since the product with \( c_{\dim X} \) identifies \( H^0 \) and \( H^2_{\dim X} \), \( \text{gr}_F^p \mathcal{O} \) is an isomorphism. Therefore, since \( \text{gr}_F^p \) is compatible with the Poincaré pairing for classes of opposite degrees and the latter is nondegenerate, \( \text{gr}_F^p \) is injective. Since \( \dim K \) is an isomorphism, \( H_{\text{ét}}^\ast(X) = \text{dim}_{\mathbb{Q}_p} H^0_{\text{ét}}(X, \mathbb{Q}_p) \), we are done.

(d) The case of \( X = \tilde{X} \setminus D \), where \( \tilde{X} \) is smooth projective, \( D \) is a strict normal crossings divisor: Let \( Y \) be an irreducible component of \( D \), \( D' \) be the union of the other components; set \( X' := \tilde{X} \setminus D' \). By induction by the number

\[
\ell \to \ell - \text{dim}_K H_{\text{ét}}^\ast(X) = \text{dim}_{\mathbb{Q}_p} H^0_{\text{ét}}(X, \mathbb{Q}_p) \],
\]

where the vertical arrows are the Gysin isomorphisms and the horizontal ones are pullbacks. There is a similar diagram for the \( \mathbb{Q}_p \)-cohomology. The horizontal maps are filtered quasi-isomorphisms, so, since \( \rho \) is compatible with pullbacks, we see that the Gysin compatibility for \( Y \hookrightarrow X \) amounts to one for \( Y \hookrightarrow \mathcal{L} \).

So we can assume that \( X \) is a line bundle \( \mathcal{L} \) over \( Y \) and \( i \) its zero section. Now the source of both \( i_\ast \)'s are dg algebras, the targets are modules over them (due to the projection \( X \to Y \)), and \( i_\ast \)'s are morphisms of modules. Thus it suffices to check that \( \rho \) identifies the images of \( 1 \). The assertion is local with respect to \( Y \); hence we can assume that \( Y \) is trivial. By base change, we reduced to the case when \( Y \) is a point, where we are done by (a).

(c) The case of a smooth projective \( X \): Let us check that the morphism of bigraded rings \( \text{gr}_F^p : \text{gr}_F H_{\text{ét}}^\ast(X) \otimes K \to H_{\text{ét}}^\ast(X, \mathbb{Q}_p) \otimes \mathcal{O} \) is an isomorphism. It is an isomorphism for \( * = 0 \). By (b), \( \text{gr}_F^p \mathcal{O} \) is acyclic and identifies the classes of a hyperplane section. Since the product with \( c_{\dim X} \) identifies \( H^0 \) and \( H^2_{\dim X} \), \( \text{gr}_F^p \mathcal{O} \) is an isomorphism. Therefore, since \( \text{gr}_F^p \) is compatible with the Poincaré pairing for classes of opposite degrees and the latter is nondegenerate, \( \text{gr}_F^p \) is injective. Since \( \dim K \) is an isomorphism, \( H_{\text{ét}}^\ast(X) = \text{dim}_{\mathbb{Q}_p} H^0_{\text{ét}}(X, \mathbb{Q}_p) \), we are done.

(d) The case of \( X = \tilde{X} \setminus D \), where \( \tilde{X} \) is smooth projective, \( D \) is a strict normal crossings divisor: Let \( Y \) be an irreducible component of \( D \), \( D' \) be the union of the other components; set \( X' := \tilde{X} \setminus D' \). By induction by the number
of components $D$ (starting with (c)), we can assume that the theorem holds for $X'$ and $Y'$. By (b), $\rho$ provides a morphism between the exact Gysin triangles for $(Y', X')$. It is a filtered quasi-isomorphism on the $X'$ and $Y'$ terms; hence it is a filtered quasi-isomorphism on the $X$ term, q.e.d.

(e) The case of arbitrary $X$: If $Y/X$ is any $h$-hypercovering of $X$, then the canonical map $R\Gamma_{\text{dR}}(X) \to R\Gamma_{\text{dR}}(Y)$ (which is the total complex of the cosimplicial system of filtered complexes $R\Gamma_{\text{dR}}(Y_i)$) is a filtered quasi-isomorphism by the construction of $R\Gamma_{\text{dR}}$, and $R\Gamma_{\et}(X, \mathbb{Q}_p) \sim R\Gamma_{\et}(Y, \mathbb{Q}_p)$ by cohomological descent (see Remark in 2.4). Thus if $\rho$ is a filtered quasi-isomorphism for every $Y_i$, then it is a filtered quasi-isomorphism for $X$. We are done, since, by de Jong (or Hironaka), one can find $Y/X$ with $Y_i$ as in (d).

Remark. $\rho$ is compatible with Chern classes of vector bundles: Indeed, $c_i(E)$ are determined in the usual way by $c_i(O(1)|_{\mathcal{E}(E)})$, so it suffices to show that $\rho$ identifies $c_i$'s of line bundles. Notice that the construction of $\rho$ extends tautologically to simplicial schemes. By (a) above, $\rho$ identifies the de Rham and étale Chern classes of the universal line bundle over the classifying simplicial scheme $B_{\mathbb{G}_m}$. For a line bundle $\mathcal{L}$ on $X$, choose a finite open covering $\{U_i\}$ of $X$ such that $\mathcal{L}$ is trivial on $U_i$; let $\pi: X' \to X$ be the Čech hypercovering. Since $\pi$ yields an isomorphism between the cohomology, it suffices to check that $\rho$ identifies the Chern classes of $\pi^* \mathcal{L}$. This is true since $\pi^* \mathcal{L}$ is the pullback of the universal line bundle by a map $X' \to B_{\mathbb{G}_m}$.

4. Proof of the Poincaré Lemma

4.1. Pick any $(V, \tilde{V}) \in \text{Var}^w_{\overline{K}}$.

Proposition. One has $L_{(V, \tilde{V})} \sim \Omega_{(V, \tilde{V})}$, the $\mathcal{O}_V$-module $\Omega_{(V, \tilde{V})} := \Omega_{(V, \tilde{V})}(\mathcal{O}, \mathcal{O}_K)$ is locally free of finite rank, and there is a canonical short exact sequence

$$0 \to \mathcal{O}_V \otimes \mathcal{O}_K \to \Omega_{(V, \tilde{V})} \to \Omega_{(V, \tilde{V})} \to 0.$$ (4.1.1)

Proof. We can assume that $V$ is connected, so $(V, \tilde{V})$ is the base change of a semi-stable $K$-pair $(U, \tilde{U})$ as in 2.2(c), i.e., $(V, \tilde{V}) = (U, \tilde{U})_\mathcal{K}$. For any finite extension $K'$ of $K$, consider an arithmetic $K$-pair $(U_{K'}, \tilde{U}_{O_{K'}}) := (U \otimes_{K} K', \tilde{U} \otimes_{O_{K}} O_{K'})$. Set $\Omega_{(V, \tilde{V})} := \Omega_{(V, \tilde{V})}(K, \mathcal{O}_{K'})$, $\Omega_{(V, \tilde{V})} := \Omega_{(V, \tilde{V})}(K, \mathcal{O}_{K'})$.

Lemma. The log scheme $(U_{K'}, \tilde{U}_{O_{K'}})$ coincides with the pullback of $(U, \tilde{U})$ by the map $\text{Spec}(K', \mathcal{O}_{K'}) \to \text{Spec}(K, \mathcal{O}_{K'})$ in the category of log schemes.

Assume the lemma for a moment. The map $(U, \tilde{U}) \to \text{Spec}(O_{K'}, \mathcal{O}_{K'})$ is log smooth and integral; by the lemma, $(U_{K'}, \tilde{U}_{O_{K'}}) \to \text{Spec}(K', \mathcal{O}_{K'})$ enjoys the same properties. So, by [8.34], $L_{(U_{K'}, \tilde{U}_{O_{K'}})}/(K', \mathcal{O}_{K'}) \sim \Omega_{(U_{K'}, \tilde{U}_{O_{K'}})} = O_{K'} \otimes_{O_{K}} \Omega_{(U, \tilde{U})}$, which is a locally free $O_{K'}$-module of finite rank. Since $L_{(K', \mathcal{O}_{K'})} \sim \Omega_{(K', \mathcal{O}_{K'})}$ (see the proof of Lemma in §3.2), the canonical exact triangle ([8.18]) $O_{U_{K'}} \otimes_{O_{K'}} L_{(K', \mathcal{O}_{K'})} \to L_{(U_{K'}, \tilde{U}_{O_{K'}})}/(K', \mathcal{O}_{K'}) \to 0$. Pass to the limit by all $K' \subset \overline{K}$ and use the lemma in §3.2; we are done.

Proof of Lemma. The underlying scheme of the pullback log scheme is $\tilde{U}_{O_{K'}}$. Let us show that its log structure map $\mathcal{M} \to O_{U_{K'}} \otimes_{O_{K'}} \Omega_{(K', \mathcal{O}_{K'})}$ is an isomorphism. The assertion is étale local, so we can assume that $\tilde{U}$ is étale over $\text{Spec}(O_{K'}, [t_a, t_b, t_c])$. 

License or copyright restrictions may apply to redistribution; see http://www.ams.org/journal-terms-of-use
(\Pi_a - \pi_K), where a, b, c are in finite sets A, B, C, \pi_K is a uniformizing parameter in \mathcal{O}_{K_U}, and U is the subscheme where all t_a, t_b are invertible. The log structure of (U, \tilde{U}) is fine with a chart N[A \sqcup B] \to \mathcal{O}_U, which sends generators m_a, m_b, of N[A \sqcup B] to t_a, t_b. Therefore \tilde{U}_{O_{K'}} is étale over Spec \mathcal{O}_K[t_a, t_b, t_c]/(\Pi_a - \pi_K), where e is the ramification index of K'/K_U, \pi_K is a uniformizing parameter in \mathcal{O}_{K'}, and the log structure \mathcal{M} has a chart M_{A,B} \to \mathcal{O}_{\tilde{U}_{O_{K'}}}, where M_{A,B} is the quotient of N[A \sqcup B] \oplus \mathbb{N} modulo the relation \Pi m_{a} = m_{\pi} (m_{\pi} is the generator of the last summand \mathbb{N}), the chart is m_a, m_b, m_{\pi} \mapsto t_a, t_b, \pi_K'. Consider an embedding M_{A,B} \hookrightarrow M'_{A,B} := e^{-1}N[A] \oplus N[B], m_a, m_b, m_{\pi} \mapsto m_a, m_b, \Pi m_{a/e}. Its image is formed by those \Pi m_{a'/e} = \Pi m_{b'}/e, n_a, n_b \in \mathbb{N}, such that n_a - n_{a'} \in e\mathbb{Z} for any a, a' \in A; thus M_{A,B} is saturated. Now the log scheme (\tilde{U}_{O_{K'}}, \mathcal{M}) is evidently log regular in the sense of [K2] 2.1; hence \mathcal{M} \overset{\sim}{\to} \mathcal{O}_{\tilde{U}_{O_{K'}}} \cap j_*\mathcal{O}_{U_{O_{K'}}}^\times \text{ by K2} [11.6], q.e.d. \footnote{We replace one t_a \in \mathcal{O}(\tilde{U}_{O_{K'}}) by t_a\pi_K/\pi_K'.} \footnote{I am grateful to Luc Illusie for the proof.}

The reference to [K2] can be replaced by the next explicit argument: it suffices to show that the map of sheaves \mathcal{M}/\mathcal{O}_{\tilde{U}_{O_{K'}}}^\times \to (\mathcal{O}_{\tilde{U}_{O_{K'}}} \cap j_*\mathcal{O}_{U_{O_{K'}}}^\times)/\mathcal{O}_{\tilde{U}_{O_{K'}}}^\times is an isomorphism. The r.h.s. is the sheaf \mathcal{D} of effective Cartier divisors supported on \tilde{U}_{O_{K'}} \setminus U_{K'}. Let \mathcal{D}^w \supset \mathcal{D} be the sheaf of the corresponding effective Weil divisors. For x \in \tilde{U}_{O_{K'}}, the fiber (\mathcal{M}/\mathcal{O}_{\tilde{U}_{O_{K'}}}^\times)_x is the quotient M_{A_x, B_x} of M_{A,B}, where A_x \subset A, B_x \subset B consist of those a, b such that t_a, t_b vanish at x. The map M_{A_x, B_x} \to D_x extends to an isomorphism M^w_{A_x, B_x} \overset{\sim}{\to} D^w_x, which identifies a generator m_{a/e} with the reduced divisor \text{div} m_a + \text{div} m_b := \text{div}(t_b). Thus M_{A_x, B_x} \hookrightarrow D_x. To show that \hookrightarrow is an isomorphism, we need to check that if \hat{D} = \pi n_a D_a + \pi n_b D_b is a Cartier divisor at x, then n_a - n_{a'} \in e\mathbb{Z} for any a, a' \in A_x.

We can assume that A = \{a, a', B = C = \emptyset, so \tilde{U}_{O_{K'}} is a semi-stable curve over O_{K'}. The exceptional divisor of its minimal desingularization \tilde{U}_{O_{K'}} is a sheaf of e - 1 projective lines P_1, \ldots, P_{e-1} with self-intersection indices (P_i, P_i) = -2. Let \hat{D} = n_a D_a^\circ + n_1 P_1 + \ldots + n_{e-1} P_{e-1} + n_{a'} D_{a'} be the pullback of D to \tilde{U}_{O_{K'}}; here D_a^\circ, D_{a'} are strict transforms of D_a, D_{a'}. One has (\hat{D}, P_i) = 0, i.e., n_{i-1} - n_i + 1 = 0 or n_i - n_{i-1} = n_i + 1 - n_{i+1}, where n_0 := n_a, n_{e+1} := n_{a'}. Thus n_{a'} - n_a = e(n_1 - n_{e+1}) \in e\mathbb{Z}, and we are done. \quad \Box

4.2. Set \Omega^a_{(V, \hat{V})} := \Lambda^a_{O_{\hat{V}}} \Omega_y(V, \hat{V}). Consider (4.1.1) as a 2-step filtration on \Omega_y(V, \hat{V}); it splits locally since \Omega_y(V, \hat{V}) is locally free. Passing to derived exterior powers, we get for any m a finite increasing filtration I on gr_F^m L\Omega_y(V, \hat{V}) = (\Lambda^m_{O_{\hat{V}}} \Omega_y(V, \hat{V}))/[-m] with gr^I_a gr_F^m L\Omega_y(V, \hat{V}) = \Omega^a_y(V, \hat{V}) \otimes_{\mathcal{O}_K} gr_F^{m-a} A_{\text{dr}}[-a], hence on gr_F^m R\Gamma_{\text{dr}}(\hat{V}, V) with

(4.2.1) \quad gr^I_a gr_F^m R_{\text{dr}}^\gamma(V, \hat{V}) = R\Gamma(\hat{V}, \Omega^a_y(V, \hat{V})) \otimes_{\mathcal{O}_K} gr_F^{m-a} A_{\text{dr}}[-a].

Let \mathcal{G} be the h-sheafification (see (2.6.1)) of the complex of presheaves (V, \hat{V}) \mapsto R\Gamma(\hat{V}, \Omega^a_y(V, \hat{V})) on \mathcal{V}_{ar^{K}}. This is a complex of h-sheaves of O_K-modules on \mathcal{V}_{ar^{K}}. Its cohomology H^k\mathcal{G} is h-sheafification of the presheaf (V, \hat{V}) \mapsto H^k(V, \Omega^a_y(V, \hat{V})) on \mathcal{V}_{ar^{K}}. Our I. is a filtration on the presheaf (V, \hat{V}) \mapsto gr_F^m R_{\text{dr}}^\gamma(V, \hat{V}); passing to h-sheafification, we get a finite filtration I. on gr_F^m A_{\text{dr}} with span [0, m] and

(4.2.2) \quad gr^I_a gr_F^m A_{\text{dr}} = \mathcal{G} \otimes_{\mathcal{O}_K} gr_F^{m-a} A_{\text{dr}}[-a].
Notice that the bottom cohomology $H^0$ of the bottom term $I_0 = \text{gr}_t^d$ is the constant sheaf $O_E$ and $\text{Cone}(\text{gr}_m^mA_{\text{dr}}^\bullet \to \text{gr}_F^mA_{\text{dr}}^\bullet) = \text{gr}_F^mA_{\text{dr}}^\bullet/H^0I_0$. Therefore, by (4.2.2), the Poincaré lemma follows from the next assertion:

**Theorem.** The cohomology $H^bG^\bullet$ are h-sheaves of $\mathbb{Q}$- (hence $\hat{K}$-) vector spaces for $(a,b) \neq (0,0)$.

**Remark.** The $p$-divisibility of $H^bG^0$, $b \neq 0$, was first proved by Bhatt [Bl1, 8.0.1].

**Exercise.** Consider a presheaf $(V, \hat{V}) \to R\Gamma(\hat{V}, L\Omega^1_{\hat{V}),(\hat{K}, O_{\hat{K}})})$; let $A_{\text{dr}}^{\text{naive}}$ be its $h$-sheafification. One has an evident map $\text{Cone}(F^1A_{\text{dr}} \to A_{\text{dr}}^0) \to A_{\text{dr}}^{\text{naive}}$. Show that the theorem implies that it is a filtered quasi-isomorphism; i.e., the triangle $F^1A_{\text{dr}} \to A_{\text{dr}}^0 \to A_{\text{dr}}^{\text{naive}}$ is exact in the filtered derived category of $h$-sheaves.

4.3. We deduce the above theorem from a more concrete assertion. As in §4.1, for an ss-pair $(U, \bar{U})$ over $\bar{K}$ we have the locally free $O_{\bar{U}}$-module of log differentials $\Omega^n_{U, \bar{U}} := \Omega^n_{U, U}/(K_U, O_{K_U})$ and its exterior powers $\Omega^a_{U, \bar{U}} := \Lambda^a\Omega^n_{U, \bar{U}}$.

Let $f : (U', \bar{U'}) \to (U, \bar{U})$ be a map in $\text{Var}_{\bar{K}}^n$ or $\text{Var}_{\bar{K}}^p$. We say that $f$ is (Hodge) $p$-negligible if the morphisms $(\tau_{>0}R\Gamma(U, O_U)) \otimes^L \mathbb{Z}/p \to (\tau_{>0}R\Gamma(U', O_U)) \otimes^L \mathbb{Z}/p$ and $R\Gamma(U, \Omega^n_{U, U}) \otimes^L \mathbb{Z}/p \to R\Gamma(U', \Omega^n_{U', U'}) \otimes^L \mathbb{Z}/p$, $a > 0$, in $D^h(O_{K_U}/p)$, vanish.

**Remark.** For $(U, \bar{U}) \in \text{Var}_{\bar{K}}^n$ and a point $K_U \to \bar{K}$, one has $R\Gamma(\bar{U}_{O_{\bar{K}}}, \Omega^n_{U, O_{\bar{K}}}) = R\Gamma(U, \Omega^n_{U, U}) \otimes^L_{O_K} O_{\bar{K}}$. Therefore the base change functor $\text{Var}_{\bar{K}}^n \to \text{Var}_{\bar{K}}^p$ (see (2.2.2)) preserves $p$-negligible maps.

**Theorem.** Every $U \in \text{Var}_{\bar{K}}^n$ admits a $p$-negligible $h$-covering. Ditto for $\hat{K}$-pairs.

The theorem implies the one in §4.2: Indeed, the $\hat{K}$-assertion shows that one has $(\tau_{>0}G^n) \otimes^L \mathbb{Z}/p = 0$ and $G^n \otimes^L \mathbb{Z}/p = 0$ for $a > 0$; since for a complex $G$ the multiplication by $p$ on $H^\bullet G$ is invertible if and only if $G \otimes^L \mathbb{Z}/p = 0$, we are done. Thus it yields the Poincaré lemma.

The above remark shows that the $K$-version of the theorem implies the $\bar{K}$-one. The proof of the $K$-version takes the rest of the section.

4.4. For the rest of §4, “pair” means “arithmetic $K$-pair” (see §2.2). We need further input from de Jong. A morphism $f : (C, \hat{C}) \to (S, \hat{S})$ of pairs is said to be a family of pointed curves (over $(S, \hat{S})$) if the map $\hat{C}_S := f^{-1}(S) \to S$ is smooth of relative dimension 1 with irreducible geometric fibers, and $D_{fS} := \hat{C}_S \setminus C$, viewed as a reduced scheme, is étale over $S$. Such an $f$ is semi-stable if, in addition, $\hat{C}/S$ is a semi-stable family of curves, and the closure $D_f$ of $D_{fS}$ in $\hat{C}$ (the horizontal divisor), viewed as a reduced scheme, is étale over $\hat{S}$ and intersects each fiber of $f$ at smooth points. A section $e : (S, \hat{S}) \to (C, \hat{C})$ of $f$ is said to be nice if $e(S)$ intersects fibers of $f$ at smooth points and $D_f \cap e(S) = \emptyset$. Families of pointed curves over $(S, \hat{S})$ form a category $\mathcal{C}(S, \hat{S})$ in the obvious manner, and a morphism of bases $\psi : (S', \hat{S}') \to (S, \hat{S})$ yields an evident pullback functor $\mathcal{C}(S, \hat{S}) \to \mathcal{C}(S', \hat{S}')$ which preserves semi-stable families. A morphism $f' \to f$ in $\mathcal{C}(S, \hat{S})$ is called an alteration if $(C', \hat{C}')$ is an alteration of $(C, \hat{C})$; it is a semi-stable alteration (of $f$) if, in addition, $f'$ is semi-stable.

**Theorem.** (a) Any family $f : (C, \hat{C}) \to (S, \hat{S})$ of pointed curves with $f : C \to \hat{S}$ projective admits a semi-stable alteration $f'$ $h$-locally over $(S, \hat{S})$. 
(b) One can find $f'$ as above which has a nice section $e$. Moreover, for a given closed subscheme $P \subset \bar{C}$ such that $f(P) = \bar{S}$ and $P \cap \tilde{C}_S \subset C$, one can find $e$ such that the map $\tilde{C}' \to \bar{C}$ sends $e(\bar{S})$ to $P$.

(c) For any semi-stable family of pointed curves $f : (C, \bar{C}) \to (S, \tilde{S})$ with $(S, \tilde{S})$ a strict ss-pair, there exists a semi-stable alteration $m : (C, \bar{C}) \to (\bar{C}, \tilde{C})$ of $f$ with $m|_{\bar{C}} = \text{id}_{\bar{C}}$ such that $m : \bar{C} \to \bar{C}$ is an isomorphism over smooth points of $f$ and $(C, \bar{C})$ is an ss-pair.

Proof. (c) is [11 3.6]. (a) follows from [12 2.4 (i),(ii)] except that de Jong does not care to control the domain of smoothness of the semi-stable alteration of $f$. A miniscule modification of his argument permits us to do this; see Appendix 1. Alternatively, (a) follows directly from a far more precise result of Temkin [11 1.5].

Let us check (b). Every pair has a canonical alteration by the union of normalizations of its irreducible components, so we assume all the way that $\bar{S}$ is normal and irreducible. Since $P$ as in (b) exists $\text{h}$-locally on $(S, \tilde{S})$ we can assume it is given. Replacing $(S, \tilde{S})$ by its alteration $(P_S, P)$, we get a section $e$ of $f$ with image in $P$. Set $C^p := C \setminus e(S)$. Then $(C^p, \bar{C}) \to (S, \tilde{S})$ is a family of pointed curves; let $f^p : (C^p, \bar{C}') \to (S, \tilde{S})$ be its semi-stable alteration as in (a). Let $D_e$ be the closure in $\bar{C}'$ of the preimage $D_{eS}$ of $e(S)$. Then $D_e$ is an étale covering of $\tilde{S}$. Let $C'$ be the preimage of $C \subset \bar{C}$ in $\bar{C}'$; then $(C', \bar{C}') \to (S, \tilde{S})$ is a semi-stable alteration of $(C, \bar{C}) \to (S, \tilde{S})$. Replacing $(S, \tilde{S})$ by its alteration $(D_{eS}, D_e)$, we get a nice section of $(C', \bar{C}')$ which sits over $e$, hence over $P$. □

Remark. In (c), every nice section of $(C, \bar{C})$ lifts to a nice section of $(C, \bar{C})$.

Corollary. Any pair $(U, \bar{U})$ has an h-covering by ss-pairs $(C, \bar{C})$, dim $C = \text{dim} \ U$, for which there is a semi-stable family of pointed curves $f : (C, \bar{C}) \to (S, \tilde{S})$ with a nice section such that $(S, \tilde{S})$ is an ss-pair and $C$ is affine over $S$ (i.e., $f(D_f) = \tilde{S}$).

Proof. It suffices to find an h-covering of $(U, \bar{U})$ by pairs $(C, \bar{C})$ with dim $C = \text{dim} \ U$ for which there exists a family of pointed curves $f : (C, \bar{C}) \to (S, \tilde{S})$ with $C$ affine over $S$ and projective $\bar{S}, \bar{C}$. The theorem transforms it then, with an input from Remark (ii) in §2.5 to preserve the dimension and de Jong's theorem in §2.3 to alter $(S, \tilde{S})$ from (b) into a strict ss-pair, into a datum with all promised properties.

By de Jong’s theorem in §2.3, we can assume that $(U, \bar{U})$ is an ss-pair and $U$ is projective and irreducible. Pick any closed point $u \in U$. It suffices to find an open neighborhood $U' \subset U$ of $u$, an alteration $(C, \bar{C})$ of $(U', \bar{U})$, and a family of curves $f : (C, \bar{C}) \to (S, \tilde{S})$ such that $f(D_f) = \tilde{S}$.

Embed $U$ into a projective space $\mathbb{P}^N_{\mathcal{O}_K}$. By Bertini, there is a plane $H \subset \mathbb{P}^N$ defined over $K$ of codimension $d$ such that $u \notin H$, $H$ intersects $\bar{U}_K$ transversally, $H \cap \bar{U}_K \subset U$, and the codimension $d-1$ plane which contains $H$ and $u$ is transversal to $\bar{U}_K$ and $\bar{U}_K \setminus U$. Let $m : \bar{C} \to \bar{U}$ be the blowup at $U \cap \mathfrak{H}_{\mathcal{O}_K}$, $p : \bar{C} \to \mathbb{P}^d_{\mathcal{O}_K}$ be the projection defined by $H$, and $\bar{C} \mapsto \bar{S} \to \mathbb{P}^d_{\mathcal{O}_K}$ be the Stein factorization of $p$ (so $\bar{S} = \text{Spec} \ p_* \mathcal{O}_{\bar{C}}$). Let $D \subset \bar{C}$ be the union of $m^{-1}(\bar{U} \setminus U)$ and the exceptional divisor (viewed as a reduced scheme), and $\bar{S} \subset \mathcal{O}_K$ be the maximal open subset $\mathcal{O}_K$.
over which \( f \) is smooth and \( f|_D \) is étale. Set \( C := f^{-1}(S) \setminus D \) and \( U' := m(C) \); notice that \( m|_C : C \to U' \). Then \( U', (C, \bar{C}) \), \( f \) satisfy the promised properties (one has \( f(D_f) = \bar{S} \) since \( D_f \) contains the exceptional divisor), q.e.d.

4.5. Let us return to the proof of the theorem in §4.3. We use induction by \( \dim U \).

By the corollary in §4.4, we can replace \((U, \bar{U})\) by \((C, \bar{C})\) as in loc. cit., so we have \( f : (C, \bar{C}) \to (S, \bar{S}) \) with a nice section \( e \) and \( C \) affine over \( S \). Notice that \((C, \bar{C})\) is log smooth over \((S, \bar{S})\) and the line bundle \( \omega_f := \Omega_{(C, \bar{C})/(S, \bar{S})} \) equals \( f'(\mathcal{O}_S)[-1] \otimes \mathcal{O}_C(D_f) \).

**Key lemma.** \( h \)-locally over \((S, \bar{S})\), one can find a semi-stable alteration \( \phi : f' \to f \) together with a nice section \( e' \) that lifts \( e \) such that \((C', \bar{C}')\) is an ss-pair and the pullback maps \( \phi^* : R^1f_*\mathcal{O}_C \to R^1f'_*\mathcal{O} \), \( f_*\omega_f \to f'_*\omega' \) are divisible by \( p^{\frac{21}{7}} \).

For a proof, see §4.6. Assuming it for the moment, let us finish the proof of the theorem in §4.3. By Remark (i) in §2.5, we can assume that the \( h \)-localization of \((S, \bar{S})\) in the Key Lemma does not change \( \dim S \). We will show that for some \( h \)-covering \((S', \bar{S}')\) of \((S, \bar{S})\) the composition \((C', \bar{C}')_{(S', \bar{S}')} \to (C', \bar{C}') \xrightarrow{\phi} (C, \bar{C})\) is \( p \)-negligible.

For any \( a \) consider the exact sequence
\[
0 \to f^*\Omega^a_{(S, \bar{S})} \to \Omega^a_{(C, \bar{C})} \to (f^*\Omega_{(S, \bar{S})}^{a-1}) \otimes \omega_f \to 0.
\]

The section \( e \) splits off \( \Omega^a_{(S, \bar{S})} \xrightarrow{\partial} Rf_*\Omega^a_{(C, \bar{C})} \) as a direct summand whose complement is \( \text{Cone}(\partial_C) \), where \( \partial_C : \Omega^1_{(S, \bar{S})} \otimes f_*\omega_f \to \Omega^a_{(S, \bar{S})} \otimes R^1f_*\mathcal{O}_C \) is the boundary map for \((4.5.1)\) (one has \( R^1f_*\omega_f = 0 \) since \( f(D_f) = \bar{S} \)). There is a similar splitting in case of \( f' \) provided by \( e' \), and the map \( \phi^* : Rf_*\Omega^a_{(C, \bar{C})} \to Rf'_*\Omega^a_{(C', \bar{C}')}(C, \bar{C}) \) is compatible with the direct sum decompositions. Now \( \phi^* \) is divisible by \( p \) on the second summand: Indeed, the Key Lemma asserts that the morphism of two-term complexes \( \phi^* : \text{Cone}(\partial_C) \to \text{Cone}(\partial_{C'}) \) is divisible by \( p \) on each term; since these are morphisms of vector bundles on \( p \)-flat \( \bar{S} \), our \( p^{-1}\phi^* \) is uniquely defined and commutes with the differentials. Thus the map \( \phi^* \otimes \text{id}_{C_1} : \text{Cone}(\partial_C) \otimes C_1 \to \text{Cone}(\partial_{C'}) \otimes C_1 \) is homotopic to zero. Apply \( R\Gamma(\bar{S}, \cdot) \) and use the induction assumption to treat the first summand \( R\Gamma(\bar{S}, \Omega^a_{(S, \bar{S})}) \); we are done.

4.6. Proof of Key Lemma. Consider the relative Picard \( \bar{S} \)-schemes \( J := \text{Pic}^0(C/\bar{S}) \) and \( J^p := \text{Pic}^0((C, D_f)/\bar{S}) \); the first scheme parametrizes line bundles \( \mathcal{L} \) on \( C \) such that the restriction of \( \mathcal{L} \) to the normalization of each irreducible component of any geometric fiber of \( f \) has degree 0; the second one parametrizes pairs \((\mathcal{L}, \gamma)\), where \( \mathcal{L} \) is as above and \( \gamma \) is a trivialization of \( \mathcal{L}|_{D_f} \). Since \((\bar{C}, D_f)\) is a semi-stable \( \bar{S} \)-family of \( d \)-pointed curves, \( d := \deg(D_f) \), our \( J \) and \( J^p \) are semi-abelian schemes (see [R]), and \( J^p \) is an extension of \( J \) by a torus \( \mathbb{G}_m^{d} / \mathbb{G}_m \).

Over \( S \) our \( J^p \) is a generalized Jacobian; let \( i : C \to J^p_S \) be the Abel-Jacobi map \( i : C \to J^p_S, x \mapsto \mathcal{O}_C(x-e) \). Let \( C^x \to C \) be the i-pullback of the multiplication by \( p \) isogeny \( p : J^p \to J^p \). Since \((\bar{C}, D_f)\) is the normalization of \( \bar{C} \) in \( C^x \). Then \( f^* : (C^x, C^x) \to (S, \bar{S}) \) is a family of pointed curves, which is an alteration of \( f \). By the theorem in §4.4, \( h \)-locally over \((S, \bar{S})\) there is a semi-stable alteration \( f' \) of \( f \)^{23}

\(^{23}\text{As elements of the groups } \text{Hom}_{\mathcal{O}_S}(R^1f_*\mathcal{O}_C, R^1f'_*\mathcal{O}_C) \text{, } \text{Hom}_{\mathcal{O}_S}(f_*\omega_f, f'_*\omega'_f).
with \((C', \bar{C}')\) semi-stable and equipped with a nice section \(e'\) which lies over \(e\). Let us check that the alteration \(\phi : f' \to f\) satisfies the conditions of the Key Lemma.

Set \(J' := \Pic^0(C'/\bar{S})\) and \(J^0 := \Pic^0((\bar{C}', D_f)/\bar{S})\). We have the pullback morphisms \(\phi^* : J \to J'\), \(J^0 \to J^0\) of our semi-abelian schemes; over \(\bar{S}\) we have the norm maps \(\phi_* : J^0 \to J_S, J^0_{\bar{S}} \to J^0_{\bar{S}}\). Both are compatible with the projections \(J^0 \to J, J^0 \to J'\).

Since \(\bar{S}\) is normal, for any semi-abelian \(\bar{S}\)-schemes \(A, B\) one has (see [FC I 2.7])

\[
(4.6.1) \quad \text{Hom}(A, B) \cong \text{Hom}(A_S, B_S).
\]

Thus \(\phi_* S\) extends to morphisms \(\phi_* : J' \to J, J^0 \to J^0\).

Notice that \(R^1 f_* \mathcal{O}_C\) is the Lie algebra of \(J\), and, by Serre duality, \(f_* \omega_J\) is dual to the Lie algebra of \(J^0\); the same is true for \(f'\). Our \(\phi^* : R^1 f_* \mathcal{O}_C \to R^1 f'_* \mathcal{O}_{C'}\) is the Lie algebra map for \(\phi^* : J \to J'\), and \(\phi^* : f_* \omega_J \to f'_* \omega_J'\) is the map between the duals to the Lie algebras for \(\phi_* : J^0 \to J^0\) (this is true over \(S\), hence everywhere since \(\bar{S}\) is \(\mathcal{O}_K\)-flat).

By construction, \(\phi_* S : J^0_{\bar{S}} \to J^0_{\bar{S}}\) factors through \(p_{J^0}\) over \(S\); i.e., it is divisible by \(p\) in \(\text{Hom}(J^0_{\bar{S}}, J^0_{\bar{S}})\). By (4.6.1), \(\phi_*\) is divisible by \(p\) in \(\text{Hom}(J^0, J^0)\). Passing to Lie algebras, we see that \(\phi^* : f_* \omega_J \to f'_* \omega_J'\) is divisible by \(p\). Similarly, \(\phi_* S : J^0_S \to J_S\) is divisible by \(p\). Notice that \(J_S, J_S^0\), being Jacobians of smooth projective curves, are self-dual abelian schemes, and \(\phi^*_S : J_S \to J_S^0\) is dual to \(\phi_* S\). Hence \(\phi^*_S\) is divisible by \(p\). So, by (4.6.1), \(\phi^* : J \to J'\) is divisible by \(p\). Passing to Lie algebras, we see that \(\phi^* : R^1 f_* \mathcal{O}_C \to R^1 f'_* \mathcal{O}_{C'}\) is divisible by \(p\), q.e.d.

\section*{Appendix}

Below is a proof of part (a) in the theorem from §4.4. It follows closely de Jong’s argument from §§2-3 of [LJ2] with a minor change of the lemma below; we refer the reader to sections of [LJ2] for details.

(i) ([LJ2] 2.10) One can assume that \(\bar{S}\) is irreducible. By [RG] 5.2.2, there is a canonical modification of \(\bar{S}\), which is projective and is an isomorphism over \(S\), such that the strict transforms of \(\bar{C}\) and \(D_f\) are flat over \(\bar{S}\). Passing to them, we can assume that all fibers of \(f\) have dimension 1, of \(f|_{D_f}\) have dimension 0.

(ii) ([LJ2] 3.4-3.5) We say that a family of pointed curves is \emph{good} if irreducible components of all its geometric fibers are curves whose normalization has genus \(\geq 2\). A good alteration is an alteration with a good source.

\textbf{Lemma.} \(f\) admits a good alteration \(h\)-locally over \((S, \bar{S})\).

\textbf{Proof of Lemma.} It suffices to find for any closed point \(s\) in \(S\) its open neighborhood \(S_{(s)} \subset S\) and an alteration \((S'_{(s)}, \bar{S}')\) of \((S_{(s)}, \bar{S})\) such that the pullback of \(f\) to \((S'_{(s)}), S)\) admits a good alteration. To do this, we define by induction a strictly increasing sequence of open subsets \(\emptyset = V_0 \subset V_1 \subset \ldots \) of \(\bar{S}\) and a sequence of finite extensions \(F = F_0 \subset F_1 \subset \ldots\) of the field \(F\) of rational functions on \(\bar{C}\) such that the normalization \(\bar{C}_i\) of \(\bar{C}\) in \(F_i\) has the following properties: (a) the map \(\bar{C}_i \to \bar{S}\) is smooth at \(s\), (b) the map \(\pi_i : C_i \to \bar{C}\) is étale at \(D_{fS}\), (c) the normalizations of irreducible components of geometric fibers of \(\bar{C}_i\) over points of \(V_i\) have genus \(\geq 2\). There is an open neighborhood \(U_i \subset S\) of \(s\) over which \(\bar{C}_i\) is smooth and \(\pi_i\) is étale at \(D_f\). The induction stops when \(V_n = S;\) set \(S_{(s)} = U_n\). The promised good alteration is \((\pi_{n-1}(C), \bar{C}_n)\) fibered over the normalization \((S'_{(s)}, S')\) of \((S_{(s)}, \bar{S})\) in \(F_n\).
Let \( x \) be the closed point of the closure of \( s \) in \( \bar{S} \). The induction produces simultaneously an auxiliary sequence of finite subsets \( T_0 \subset T_1 \subset \ldots \) of closed points of \( \bar{C} \); it starts with \( T_0 := \) the union of \( D_{f,S} \) and the set of nonregular points of \( \bar{C} \). The induction step: suppose we have \( V_{i-1}, F_{i-1}, T_{i-1} \); let us construct \( V_i, F_i, T_i \) assuming that \( V_{i-1} \neq \bar{S} \). Let \( y \) be any closed point in \( \bar{S} \setminus V_{i-1} \). Since \( \bar{S} \) is projective, there is an affine open \( V \) which contains \( x \) and \( y \). Let \( \mathcal{L} \) be a very ample line bundle on \( \bar{C} \). Replacing it by a sufficiently high power, we can assume that \( \Gamma(\bar{C}_V, \mathcal{L}) \to \Gamma(\bar{C}_S, \mathcal{L}) \times \Gamma(\bar{C}_y, \mathcal{L}) \). One can find a finite unramified extension \( K' \) of \( K \) with residue field \( k' \) and two sections \( \gamma_1, \gamma_2 \in \Gamma(C_V, \mathcal{L}) \otimes O_{K'}, \) which do not vanish at the generic points of irreducible components of \( \bar{C}_x, \bar{C}_y, \) such that \( t = \gamma_1/\gamma_2 \) yields generically étale finite maps \( t_x : \bar{C}_x \otimes k' \to \mathbb{P}^1 \otimes k', \; t_y : \bar{C}_y \otimes k' \to \mathbb{P}^1 \otimes k' \) étale over \( \{0, 1, \infty\} \) and such that \( t_x(T_{i-1}) \cap \{0, 1, \infty\} = \emptyset \). Pick \( \ell \geq 5 \) prime to \( p \), and let \( F_i \) be an extension of \( F_{i-1} \) generated by \( K', \mu_{\ell}, t^{1/\ell}, \) and \( (1-t)^{1/\ell} \). Let \( T_i \) be the union of \( T_{i-1} \) and the set of ramification points of \( t_x \). The normalization \( \bar{C}_i \) of \( C \) in \( F_i \) satisfies (a), (b), and satisfies (c) over some open set \( V_i \) which contains \( V_{i-1} \) and \( y \). We are done. \( \square \)

(iii) It remains to show that every good \( f \) admits a semi-stable alteration after a possible alteration of the base. The genus of the generic fiber of \( f \) is \( \geq 2 \), so \( (\bar{C}_S, D_{f,S}) \) is a stable \( n \)-pointed curve over \( S \) (where \( n \) is the degree of \( D_{f,S} \) over \( S \)). The Deligne-Mumford stack of stable \( n \)-pointed curves is proper, so, after replacing \( (S, \bar{S}) \) by an alteration, we can assume that \( (\bar{C}_S, D_{f,S}) \) extends to a stable \( n \)-pointed curve \( (\bar{C}', D_{f'}) \) over \( \bar{S} \) (see [dJ2, 3.8]). We have a semi-stable family of pointed curves \( f' : (\bar{C}', \bar{C}') \to (S, \bar{S}), \bar{C}' := C' \setminus D_{f'} \). By [dJ2, 3.10], the goodness of \( f \) implies that, after a possible alteration of \( \bar{S} \), the evident morphism \( \bar{C}'_S \to \bar{C}_S \) extends to a morphism \( f' \to f \), and we are done. \( \square \)

ACKNOWLEDGMENTS

This work was prompted by a discussion with Kobi Kremnizer (and watching the moon over a meadow in Oxford). The author is very grateful to him and to Bhargav Bhatt, Volodya Drinfeld, John Francis, Luc Illusie, David Kazhdan, Jacob Lurie, Madhav Nori, and Misha Temkin for explanations, questions, and corrections of mistakes.

REFERENCES

\(^{22}\) If the residue field of \( K \) is infinite, one can take \( K' = K \).
