Extensions of Symmetric Integration Formulas*

By A. H. Stroud

1. Introduction. Assume we are given an integration formula for the m-dimensional cube \( C_m \) of the form

\[
\int_{-1}^{1} \cdots \int_{-1}^{1} f(x_1, \ldots, x_m)dx_1 \cdots dx_m \approx \sum_{j=1}^{N} A_j f(v_{j1}, \ldots, v_{jm})
\]

which is exact for all polynomials of degree \( \leq d \); this is equivalent to assuming (1) is exact for all monomials

\[
x_1^{a_1}x_2^{a_2} \cdots x_m^{a_m}, \quad a_1, \ldots, a_m \text{ nonnegative integers },
\]

\[
0 \leq a_1 + a_2 + \cdots + a_m \leq d.
\]

We say that such a formula (1) has degree \( d \).

We say that formula (1) is symmetric if the right side of (1) is not changed under any of the \( m! \) permutations of the variables \( x_1, x_2, \ldots, x_m \). In other words (1) is symmetric provided that if the formula contains the point

\[(v_{j1}, v_{j2}, \ldots, v_{jm}) \quad \text{coeff. } A_j\]

then the formula also contains the point

\[(v_{jp_1}, v_{jp_2}, \ldots, v_{jp_m}) \quad \text{coeff. } A_j\]

where \( (p_1, p_2, \ldots, p_m) \) is any permutation of \( (1, 2, \ldots, m) \).

In this article we show how a symmetric formula (1) of degree \( d \leq 2m + 1 \) for \( C_m \) can be used to construct a symmetric formula of the same degree for \( C_n \), \( n > m \).

Following Hammer and Stroud [2] we say that formula (1) is fully-symmetric if the right side of (1) is not changed under any of the \( 2^m(m!) \) linear transformations of \( C_m \) onto itself. Lyness [3] has given a method by which a fully-symmetric formula of degree \( d \leq 2m + 1 \) can be used to construct a fully-symmetric formula of degree \( d \) for \( C_n \), \( n > m \). Lyness defines a formula for \( C_n \) constructed by this method as an extension of the formula for \( C_m \). The result of this article is a variation of the result of Lyness.

In what follows we use the notation

\[
I_{C_m}(x_1^{a_1}x_2^{a_2} \cdots x_m^{a_m}) = \int_{-1}^{1} \cdots \int_{-1}^{1} x_1^{a_1}x_2^{a_2} \cdots x_m^{a_m}dx_1 \cdots dx_m
\]

and \( V_m = I_{C_m}(1) = 2^m \). We note for future reference that if

\[
I_{C_m}(x_1^{a_1}x_2^{a_2} \cdots x_m^{a_m}) = c_{a_1, \ldots, a_m} V_m
\]

then

* This work was supported by NSF Grant GP-5675.
\[ I_{C_n}(x_1^{a_1}x_2^{a_2} \cdots x_m^{a_m}) = c_{a_1 \cdots a_m}V_n. \]

2. The Method of Extension. We assume formula (1) is symmetric and we write the points and coefficients in this formula as follows:

\[ (\mu_{i_1}, \cdots, \mu_{i_1}, \cdots), \quad (\mu_{i_2}, \cdots, \mu_{i_2}, 0, \cdots, 0)_s \quad A_i = a_iV_m, \]

\[ m_{i_1} \text{ times} \quad m_{i_2} \text{ times} \quad m - m_{i_1} \text{ times} \]

\[ m_i = m_{i_1} + \cdots + m_{i_k}, 0 \leq m_i \leq m, 1 \leq m_{i_1} \leq m, \cdots, 1 \leq m_{i_k} \leq m, \mu_{ir} \neq \mu_{is} \text{ if } r \neq s, i = 1, 2, \cdots, M. \]

Here \( (\nu_{i_1}, \cdots, \nu_{i_m})_s \) denotes the set of points consisting of the point \( (\nu_{i_1}, \cdots, \nu_{i_m}) \) and all points obtained by permuting the coordinates \( \nu_{i_1}, \cdots, \nu_{i_m} \) in all possible ways. \( A_i \) is the coefficient of each point in the set of points (2).

We define the extension of formula (2) to be the formula for \( C_n \) consisting of the following:

\[ (\mu_{i_1}, \cdots, \mu_{i_1}, \cdots), \quad (\mu_{i_2}, \cdots, \mu_{i_2}, 0, \cdots, 0)_s \quad B_{i,j_1,\cdots,j_{ik}}, \]

\[ j_{i_1} \text{ times} \quad j_{i_2} \text{ times} \quad n - j, \quad j = j_{i_1} + \cdots + j_{ik}, \]

for all possible choices of \( j_{i_1}, \cdots, j_{ik} \) which satisfy \( 0 \leq j_{i_1} \leq m_{i_1}, \cdots, 0 \leq j_{ik} \leq m_{ik} \) and for all \( i, \quad i = 1, 2, \cdots, M. \) The coefficient of the points (3) is

\[ B_{i,j_1,\cdots,j_{ik}} = \frac{(-1)^{m_i-j}Z(n, m, m_{i_1}, j_{i_1})}{(m_{i_1} - j_{i_1})! \cdots (m_{ik} - j_{ik})!} a_iV_n \]

where \( Z(n, m, m_{i_1}, j_{i_1}) = (n - m + m_{i_1} - j_{i_1} - 1)!/(n - m - 1)! \).

We now state:

**Theorem 1.** If formula (2) for \( C_m \) has degree \( d \), where \( d \leq 2m + 1 \), then the points (3) with coefficients (4) are a formula of degree \( d \) for \( C_n, n > m \).

We do not know how to prove this theorem for all \( m \) but we believe it to be true. We have verified it for \( m \leq 5 \); we will show how it can be verified for \( m = 4 \).

To start let us assume that the points (2) have the special form

\[ (\mu_{i_1}, \mu_{i_2}, \mu_{i_3}, \mu_{i_4})_s \quad A_i = a_iV_4 \]

for all \( i = 1, 2, \cdots, M. \) The points (3) and coefficients (4) will then be

\[ (\mu_{i_1}, \mu_{i_2}, \mu_{i_3}, 0, \cdots, 0)_s \quad B_{i,2,2} = a_iV_n, \]

\[ (\mu_{i_1}, \mu_{i_2}, 0, 0, \cdots, 0)_s \quad B_{i,2,1} = -(n - 4)a_iV_n, \]

\[ (\mu_{i_1}, \mu_{i_2}, 0, 0, \cdots, 0)_s \quad B_{i,1,2} = \frac{(n - 3)(n - 4)}{2} a_iV_n, \]

\[ (\mu_{i_1}, \mu_{i_2}, 0, 0, \cdots, 0)_s \quad B_{i,0,2} = \frac{(n - 2)(n - 3)(n - 4)}{4} a_iV_n, \]

\[ (\mu_{i_1}, \mu_{i_2}, 0, 0, 0, \cdots, 0)_s \quad B_{i,1,1} = -(n - 3)(n - 4)a_iV_n, \]

\[ (\mu_{i_1}, 0, 0, 0, \cdots, 0)_s \quad B_{i,1,0} = -(n - 2)(n - 3)(n - 4) a_iV_n, \]

\[ (0, 0, 0, 0, 0, \cdots, 0)_s \quad B_{i,0,0} = \frac{(n - 1)(n - 2)(n - 3)(n - 4)}{4} a_iV_n, \]

\[ i = 1, 2, \cdots, M. \]
EXTENSIONS OF SYMMETRIC INTEGRATION FORMULAS

Here $B_{i,0,0}$ is only part of the coefficient of the point $(0, 0, \cdots, 0)$ in the extended formula; this coefficient is $\sum_{i=1}^{M} B_{i,0,0}$.

Let $\alpha_1$, $\alpha_2$, $\alpha_3$, $\alpha_4$ be fixed, but arbitrary, positive integers which satisfy

\begin{align*}
0 &< \alpha_1 \leq d , \\
0 &< \alpha_1 + \alpha_2 \leq d , \\
0 &< \alpha_1 + \alpha_2 + \alpha_3 \leq d , \\
0 &< \alpha_1 + \alpha_2 + \alpha_3 + \alpha_4 \leq d ,
\end{align*}

where $d \leq 9$. We show that formula (6) is exact for each of the five monomials

\begin{align*}
(7) &
x_{1}^{\alpha_1}x_{2}^{\alpha_2}x_{3}^{\alpha_3}x_{4}^{\alpha_4}, \\
x_{1}^{\alpha_1}x_{2}^{\alpha_2}x_{3}^{\alpha_3}, \\
x_{1}^{\alpha_1}x_{2}^{\alpha_2}, \\
x_{1}^{\alpha_1}, \quad 1.
\end{align*}

Consider, for example, the monomial $x_{1}^{\alpha_1}x_{2}^{\alpha_2}$. The assumption that (5) is a formula of degree $d$, $d \leq 9$, implies that

\begin{align*}
V_{m} \sum_{i=1}^{M} a_{i} \left[ \mu_{1}^{\alpha_1} \mu_{2}^{\alpha_2} + 2 \mu_{1}^{\alpha_1} \mu_{2}^{\alpha_2} + 2 \mu_{1}^{\alpha_1} \mu_{2}^{\alpha_2} + \mu_{1}^{\alpha_1} \mu_{2}^{\alpha_2} \right] = I_{C_{n}}(x_{1}^{\alpha_1}x_{2}^{\alpha_2}).
\end{align*}

Using formula (6) to approximate $I_{C_{n}}(x_{1}^{\alpha_1}x_{2}^{\alpha_2})$ we can verify that we obtain

\begin{align*}
V_{n} \sum_{i=1}^{M} a_{i} \left[ \mu_{1}^{\alpha_1} \mu_{2}^{\alpha_2} + 2 \mu_{1}^{\alpha_1} \mu_{2}^{\alpha_2} + 2 \mu_{1}^{\alpha_1} \mu_{2}^{\alpha_2} + \mu_{1}^{\alpha_1} \mu_{2}^{\alpha_2} \right].
\end{align*}

By the remark made at the end of Section 1 this shows that formula (6) is exact for $x_{1}^{\alpha_1}x_{2}^{\alpha_2}$. In a similar way we can verify that (6) is exact for all the monomials (7). By symmetry it follows that (6) is also exact for all monomials

\begin{align*}
\sum_{j=p_{1}, p_{2}, p_{3}, p_{4}} a_{j}^{\alpha_1} a_{j}^{\alpha_2} a_{j}^{\alpha_3}, \\
\sum_{j=p_{1}, p_{2}, p_{3}} a_{j}^{\alpha_1} a_{j}^{\alpha_2} a_{j}^{\alpha_3}, \\
\sum_{j=p_{1}, p_{2}} a_{j}^{\alpha_1} a_{j}^{\alpha_2}, \\
x_{p_{1}} a_{p_{1}}
\end{align*}

where $(p_{1}, p_{2}, p_{3}, p_{4})$ is any permutation of $(1, 2, 3, 4)$.

To complete the proof that (6) has degree $d$ there only remains to show that (6) is exact for all monomials of the form

\begin{align*}
(8) &
x_{p_{1}}^{\alpha_1}x_{p_{2}}^{\alpha_2} \cdots x_{p_{s}}^{\alpha_s}, \quad 4 \leq s \leq n, \alpha_{i} > 0, i = 1, \cdots, s, 0 < \alpha_{1} + \cdots + \alpha_{s} \leq 9.
\end{align*}

We note that in each monomial (8) the $\alpha_{i}$ cannot all satisfy $\alpha_{i} \geq 2$, $i = 1, \cdots, s$. Therefore, for at least one $i$ we must have $\alpha_{i} = 1$. This means that

\begin{align*}
I_{C_{n}}(x_{p_{1}}^{\alpha_1}x_{p_{2}}^{\alpha_2} \cdots x_{p_{s}}^{\alpha_s}) = 0.
\end{align*}

But formula (6) also gives zero for the integral of (8) because each point of (6) has at most four nonzero coordinates.

In a similar way we can verify that if a formula (2) for $C_{4}$ consists of any collection of points and has degree $d \leq 9$ then the extended formula (3) also has degree $d$.

3. An Example. Albrecht and Collatz [1] have given the following 5th-degree 7-point formula for $C_{2}$:

\begin{align*}
(0, 0) & 2V_{2}/7 , \\
(r, r) & 25V_{2}/168 , \\
(-r, -r) & 25V_{2}/168 , \\
(s, -t) & 5V_{2}/48 , \\
(-s, t) & 5V_{2}/48 , \\
r^{2} & = 7/15, \quad s^{2} = (7 + (24)^{1/2})/15, \quad \ell^{2} = (7 - (24)^{1/2})/15.
\end{align*}
The extension of this formula gives the following 5th-degree formula for $C_n$ which uses $3n^2 + 3n + 1$ points:

$$\pm (r, r, 0, \ldots, 0)_s \quad 25V_n/168,$$

$$\pm (r, 0, 0, \ldots, 0)_s \quad -25(n - 2)V_n/168,$$

$$\pm (s, -t, 0, \ldots, 0)_s \quad 5V_n/48,$$

$$\pm (s, 0, 0, \ldots, 0)_s \quad -5(n - 2)V_n/48,$$

$$\pm (t, 0, 0, \ldots, 0)_s \quad -5(n - 2)V_n/48,$$

$$\pm (0, 0, 0, \ldots, 0)_s \quad (5n^2 - 15n + 14)V_n/14.$$

Here $\pm (r, r, 0, \ldots, 0)_s$ denotes the two sets of points $(r, r, 0, \ldots, 0)_s$ and $(-r, -r, 0, \ldots, 0)_s$.

4. Remarks. If formula (2) for $C_m$ is fully-symmetric and if we denote it by $R^{(m)}$ as Lyness [3] does, then our extension of $R^{(m)}$ coincides with the formula denoted by Lyness as $E_m^{n}(0)R^{(m)}$. We have not discussed formulas which correspond to the $E_m^{n}(\gamma)R^{(m)}$, $\gamma \neq 0$, of Lyness.

The method described in Section 2 for extending a formula for $C_m$ can also be applied to certain other special regions. Let $R_1$ be a one-dimensional region and $w_1(x) \geq 0$ a weight function which satisfy $\int_{R_1} w_1(x)x^kdx = 0$, $k$ an odd integer, $0 < k \leq d$. Let $R_m = R_1 \times R_1 \times \cdots \times R_1$ and $w_m(x_1, \ldots, x_m) = w_1(x_1) \cdots w_1(x_m)$. Given a symmetric integration formula of degree $d \leq 2m + 1$ for

$$\int_{R_m} \cdots \int_{R_m} w_m(x_1, \ldots, x_m)f(x_1, \ldots, x_m)dx_1 \cdots dx_m,$$

we can extend this formula—by a method exactly similar to the method for $C_m$—to obtain a symmetric formula of degree $d$ for

$$\int_{R_n} \cdots \int_{R_n} w_n(x_1, \ldots, x_n)f(x_1, \ldots, x_n)dx_1 \cdots dx_n.$$

As an example of (9) we have

$$\int_{-\infty}^{\infty} \cdots \int_{-\infty}^{\infty} \exp \left(-x_1^2 - \cdots - x_m^2\right)f(x_1, \ldots, x_m)dx_1 \cdots dx_m.$$

Lyness [4] has discussed extensions of fully-symmetric formulas for (10).

The method of extension discussed here (and by Lyness) has the undesirable property of producing integration formulas with both positive and negative coefficients. Hopefully, methods of extension will be found which do not introduce negative coefficients.
