The Stability of Pseudospectral-Chebyshev Methods*

By David Gottlieb**

Abstract. The stability of pseudospectral-Chebyshev methods is demonstrated for parabolic and hyperbolic problems with variable coefficients. The choice of collocation points is discussed. Numerical examples are given for the case of variable coefficient hyperbolic equations.

1. Introduction. The purpose of this paper is to analyze spectral Chebyshev collocation (otherwise known as pseudospectral) methods for hyperbolic and parabolic problems. We shall show that these methods converge at a rate that is faster than that of finite differences. The analysis is based upon results presented in [1]. This reference outlines the general theory of convergence of spectral methods and proves that if a spectral method is algebraically stable in some norm, then the method is strongly stable in an algebraically equivalent new norm. If in addition the method is consistent by virtue of its truncation error tending to zero in this new norm, then convergence is implied.

The application of this theory to hyperbolic and parabolic problems had been discussed in [1] mainly for constant coefficient hyperbolic and parabolic problems and, in the case of Chebyshev methods, mainly for the Galerkin and Tau methods. In this paper we discuss the collocation methods and prove stability for the variable coefficient case. The new idea that enables us to establish stability for collocation methods is to use a formula for Gauss-type integration. We use the positive weights given by this formula as the new norm and prove energy conservation in this norm. Using the same technique, a new proof is presented for variable coefficient hyperbolic and parabolic problems when solved by spectral-Chebyshev methods using Tau methods. These proofs are more general than those in [1] in the sense that they include the variable coefficient case.

1. A numerical solution of the problem

\[ u_t = Lu, \]

where \( u \in H \), \( H \) is a Hilbert space and \( L \) is an infinite-dimensional operator, consists of two steps. The first is to choose a finite-dimensional subspace of \( H \), say
(1.1) becomes

$$\frac{\partial u_N}{\partial t} = P_N L u_N, \quad u_N \in B_N,$$

which may be solved on a computer. Spectral Chebyshev methods are defined by choosing $B_N$ as the $N$-dimensional space spanned by polynomials of degree $N + k - 1$ that satisfy boundary conditions.

There are three ways which have been used to choose the operator $P_N$, namely Galerkin, Tau, and collocation.

In the Galerkin method for homogeneous boundary conditions, we choose $\phi_n$, $n = 1, \ldots, N$, as the basis of $B_N$ and solve

$$\left( \frac{\partial u_N}{\partial t} - L u_N, \phi_n \right) = 0, \quad n = 1, \ldots, N,$$

(1.3)

$$u_N = \sum_{n=1}^{N} a_n \phi_n.$$

For the Tau method, we choose $\{\phi_n\}$ to be a set of orthogonal functions such that $(\phi_n, \phi_m) = \delta_{nm}$ and expand

$$u_N = \sum_{n=1}^{N+k} a_n \phi_n,$$

where $k$ is the number of boundary conditions. Then set

$$\left( \frac{\partial u_N}{\partial t} - L u_N, \phi_n \right) = 0, \quad n = 1, \ldots, N.$$

(1.4)

The condition $u_N \in B_N$ provides the other $k$ equations.

In the collocation method, we set

$$u_N = \sum_{n=1}^{N} a_n \phi_n,$$

and require

$$\frac{\partial u_N}{\partial t} - L u_N = 0 \quad \text{for} \quad x_j, \quad j = 1, \ldots, N.$$

(1.5)

It had been observed by Orszag [1] and Kreiss and Oliger [2] that the collocation method can be carried out efficiently in the physical space in contrast to the Galerkin and Tau methods which must be solved in the transform space. This fact enables one to use the collocation method efficiently for nonlinear equations. We refer the reader to [1] for further discussion of this fact.

In the next sections we will illustrate the above procedure applied to parabolic and hyperbolic equations.

2. Consider the equation

$$u_t = S(x)u_{xx}, \quad -1 < x < 1, 0 < \delta < S(x),$$

$$u(\pm 1, t) = 0.$$

In the Galerkin-Chebyshev method, we choose

$$\phi_n = T_n - T_0, \quad n \text{ even},$$

$$\phi_n = T_n - T_1, \quad n \text{ odd},$$

(2.2)

where $T_n(x) = \cos(n \cos^{-1} x)$. 
We expand $u_N = \sum_{n=0}^{N} a_n \phi_n(x)$ so that $u_N(\pm 1, t) = 0$ and set

$$
(2.3) \quad \int_{-1}^{1} \left[ \frac{\partial u_N}{\partial t} - S(x) \frac{\partial^2 u_N}{\partial x^2} \right] \frac{\phi_n}{\sqrt{1-x^2}} \, dx = 0, \quad n = 2, \ldots, N.
$$

It is readily seen that for nonconstant $S(x)$, it is difficult to solve the equations for (2.3). Orszag has found some efficient transform methods to evaluate

$$
\int_{-1}^{1} S(x) \frac{\partial^2 u_N}{\partial x^2} \frac{\phi_n}{\sqrt{1-x^2}}.
$$

In general, however, solving (2.3) for the coefficients $\{a_n\}$ is time-consuming.

In the Tau method, we set

$$
\tau N = 2 \sum_{n=0}^{N} a_n T_n(x),
$$

and require

$$
\int_{-1}^{1} \frac{1}{\sqrt{1-x^2}} \left( \frac{\partial u_N}{\partial t} - S(x) \frac{\partial^2 u_N}{\partial x^2} \right) T_n \, dx = 0, \quad n = 0, \ldots, N,
$$

together with

$$
(2.4) \quad \sum_{n=0}^{N+2} a_n T_n(1) = \sum_{n=0}^{N+2} a_n = 0,
$$
$$
\sum_{n=0}^{N+2} a_n T_n(-1) = \sum_{n=0}^{N+2} (-1)^n a_n = 0.
$$

We face the same complications for getting the coefficients as we had for the Galerkin method.

In the collocation method, we set

$$
u_N = \sum_{n=2}^{N} f_n(t) \phi_n(x),
$$

where the $\phi_n$'s are defined in (2.2). Then we demand

$$
(2.5) \quad \frac{\partial u_N}{\partial t} - S(x) \frac{\partial^2 u_N}{\partial x^2} = 0 \quad \text{at} \quad x = x_j, \quad j = 1, \ldots, N - 1,
$$

for some points $x_j$. If the $x_j$ are chosen to be $\cos \pi j/N$ so that the boundary values are included, there is an efficient way to solve (2.5), by taking advantage of the orthogonality of the trigonometric functions. Set

$$
u_N(x) = \sum_{n=0}^{N} a_n T_n(x), \quad \nu_N(x_j) = \sum_{n=0}^{N} a_n T_n(x_j), \quad 0 < j < N.
$$

Then

$$
(2.5a) \quad a_n = \frac{2}{Nc_n} \sum_{k=0}^{N} \frac{1}{c_k} \nu_N(x_k) \cos \frac{\pi nk}{N}, \quad c_0 = c_N = 2, c_k = 1, 1 < k < N - 1.
$$

Using the properties of Chebyshev polynomials, we may set

$$
\frac{\partial^2 u_N(x_j)}{\partial x^2} = \sum_{n=0}^{N} b_n T_n(x_j),
$$
where the coefficients $b_n$ may be found from
\[ c_n b_n = \sum_{p=0}^{n} p(p^2 - n^2) a_p. \]

We refer the reader to [1] for the derivation of the last equation. We then go back to the physical space and solve
\[ \frac{\partial u_N}{\partial t}(x_j) = S(x_j) \frac{\partial^2 u_N}{\partial x^2}(x_j), \quad j = 1, \ldots, N - 1, \]
\[ u_N(x_0) = u_N(x_N) = 0. \]

This procedure is very efficient and may be generalized without any problem to nonlinear equations. In practice we would use the Chebyshev polynomials to interpolate $u$ spatially and then to evaluate the spatial derivative at the desired points $x_j$. Finally the solution would be advanced in time using the original nonlinear equation to find the time derivative at the points $x_j$ in the physical space.

In order to prove convergence we need the following two results.

**Lemma 1.** Let $u$ satisfy $u(\pm 1) = 0$ and have a continuous first derivative. Then
\[ \int_{-1}^{1} \frac{u u_{xx}}{\sqrt{1 - x^2}} \, dx < 0. \]

For the proof we refer the reader to [1, p. 82].

**Lemma 2.** Let $x_j = \cos \pi j/N$, $j = 0, \ldots, N$. Then there exist $w_j > 0$, $j = 0, \ldots, N$, such that
\[ \int_{-1}^{1} \frac{f(x)}{\sqrt{1 - x^2}} \, dx = \sum_{j=0}^{N} f(x_j)w_j, \quad \sum_{j=0}^{N} w_j = \pi, \]
for any $f(x)$ which is a polynomial of degree at most $2N - 1$.

This lemma can be found in [5]. We are now ready to prove the stability of the Chebyshev collocation method for the heat equation.

**Theorem (Stability).** Let $u_N$ be the Chebyshev collocation approximation (2.5) to the heat equation (2.1). Then
\[ \sum_{j=0}^{N} \frac{u_N^2(x_j, t)}{S(x_j)} w_j < \sum_{j=0}^{N} \frac{u_N^2(x_j, 0)}{S(x_j)} \frac{w_j}{S(x_j)}. \]

**Proof.** Since
\[ \frac{\partial u_N}{\partial t}(x_j, t) = S(x_j) \frac{\partial^2 u_N}{\partial x^2}(x_j), \quad j = 1, \ldots, N - 1, \]
and
\[ u_N(x_0) = u_N(x_N) = 0, \]
we get
\[ \sum_{j=0}^{N} u_N(x_j) \frac{\partial u_N}{\partial t}(x_j) \frac{w_j}{S(x_j)} = \sum_{j=0}^{N} u_N(x_j) \frac{\partial^2 u_N}{\partial x^2}(x_j)w_j. \]
By Lemma 2 and the fact that the degree of \( u_N \partial^2 u_N / \partial x^2 \) is \( 2N - 2 \), we get
\[
\sum_{j=0}^{N} u_N(x_j) \frac{\partial^2 u_N}{\partial x^2}(x_j) w_j = \int_{-1}^{1} \frac{1}{\sqrt{1 - x^2}} u_N \frac{\partial^2 u_N}{\partial x^2} \, dx < 0.
\]
The last inequality follows from Lemma 1, since \( u_N(\pm 1, t) = 0 \). Therefore,
\[
\frac{d}{dt} \sum_{j=0}^{N} u_N^2(x_j) \frac{w_j}{S(x_j)} < 0,
\]
and (2.16) follows.

The next step for showing convergence is to show that the truncation error tends to zero as \( N \) tends to infinity. In view of the discussion in [1, p. 48] the truncation error is given by

(2.10) \[ \left\| P_N S(x) \frac{\partial^2}{\partial x^2} P_N - P_N S(x) \frac{\partial^2}{\partial x^2} \right\| u \]
where \( u \in C^\infty \) is the solution to (2.1), \( P_N f(x) \) is a polynomial of degree \( N \) that interpolates the function \( f(x) \) at the points \( x_j \), and
\[
\| g \| = \left( \sum_{j=0}^{N} \frac{g^2(x_j)}{S(x_j)} w_j \right)^{1/2}, \quad x_j = \cos \frac{\pi j}{N}, j = 0, \ldots, N.
\]

**THEOREM (CONSISTENCY).** Let \( u, P_N \) and \( \| \cdot \| \) be defined as above. Then

(2.11) \[ \left\| P_N \left( S(x) \frac{\partial^2}{\partial x^2} P_N - S(x) \frac{\partial^2}{\partial x^2} \right) u \right\| = O\left( \frac{1}{N^r} \right), \]
for any positive \( r \).

**Proof.** From (2.5a) we can express \( P_N u \) by
\[
P_N u = \sum_{n=0}^{N} a_n T_n(x),
\]
where
\[
a_n = \frac{2}{N} \sum_{j=0}^{N} \frac{u(x_j)}{c_j} T_n(x_j).
\]
On the other hand
\[
u(x) = \frac{a_0}{2} T_0 + \sum_{n=1}^{\infty} a_n T_n(x),
\]
where
\[
a_n = \frac{2}{\pi} \int_{-1}^{1} \frac{u(x) T_n(x)}{\sqrt{1-x^2}} \, dx.
\]
It is well known that \( a_n = O(1/n^p) \), for any \( p \). Moreover, \( a_n \) can be expressed in terms of the \( a_n \)'s by the formula

(2.12) \[ a_n = \frac{1}{N} a_0 \sum_{j=0}^{N} T_k(x_j) T_n(x_j) c_j + \frac{2}{N} \sum_{k=1}^{N} a_k \sum_{j=0}^{N} T_k(x_j) T_n(x_j) c_j
\]
\[ = a_n + a_{2N-n} + a_{4N-n} + \ldots.
\]
and therefore

\begin{equation}
S(x) \frac{\partial^2}{\partial x^2} P_N u - S(x) \frac{\partial^2}{\partial x^2} u = S(x) \sum_{n=0}^{N} (a_n - a_n) T_n'' - S(x) \sum_{n=N}^{\infty} a_n T_n''.
\end{equation}

Define

\[ g(x) = S(x) \sum_{n=N}^{\infty} a_n T_n''. \]

Then

\[ \|g(x)\|^2 = \sum_{j=0}^{N} S(x_j) \left( \sum_{n=N}^{\infty} a_n T_n''(x_j) \right)^2 w_j = O\left( \frac{1}{N^r} \right). \]

Moreover, since \(|a_n - a_n| = O(1/N^r)\) by (2.12), we get

\[ \left\| S(x) \frac{\partial^2}{\partial x^2} P_N u - S(x) \frac{\partial^2}{\partial x^2} u \right\| = O\left( \frac{1}{N^r} \right), \]

and since \(\|P_N\| = 1\), (2.11) is proven.

3. In this section we would like to treat the hyperbolic equation

\begin{equation}
\begin{aligned}
&u_t + S(x) u_x = 0, \\ &S(x) > 0, \\ &|x| < 1,
\end{aligned}
\end{equation}

\[ u(1, t) = 0. \]

We concentrate upon the collocation method. There are currently two ways of performing the collocation method. The first one is to collocate at the point \(x_k = \cos \pi k/N, k = 1, \ldots, N\), and to use the boundary condition for \(x_0 = 1\). This means that we collocate at \(N - 1\) points in the interior of the domain and also at the outflow boundary; we do not collocate at \(x = 1\) since a boundary condition is imposed at this point. The other way is to collocate at the points \(x_k = \cos \pi k/N, k = 1, \ldots, N - 1\), and to use the boundary condition at \(x_0 = 1\). This amounts to using \(N - 1\) interior points for collocation and to impose a boundary condition at the inflow. The outflow boundary is not treated at all. We would now like to show how to carry out these two methods effectively.

In order to carry out the first one, we expand

\begin{equation}
\begin{aligned}
&u_N(x_n, t) = \sum_{k=0}^{N} a_k T_k(x_n), \\ &n = 0, \ldots, N, x_n = \cos \frac{\pi n}{N},
\end{aligned}
\end{equation}

and solve for \(a_k\)

\begin{equation}
\begin{aligned}
&a_k = \frac{2}{N c_k} \sum_{j=0}^{N} \frac{1}{c_j} u_N(x_j, t) \cos \frac{\pi j k}{N}, \\ &c_0 = c_N = 2, c_i = 1, 0 \neq i \neq N.
\end{aligned}
\end{equation}

Equation (3.3) is evaluated by using the Fast Fourier Transform (FFT) method. Now

\begin{equation}
\frac{\partial u_N}{\partial x} (x_n, t) = \sum_{k=0}^{N} b_k T_k(x_n),
\end{equation}

where

\begin{equation}
b_k = \frac{1}{c_k} \sum_{k=p+1}^{N} \sum_{k+p \text{ odd}} 2pa_p.
\end{equation}
The evaluation of the right-hand side of Eq. (3.4) is carried out using FFT. Then Eq. (3.5) is solved for the \( b_k \)'s with \( O(N) \) operations, that is a simple recursive formula is used,

\[
b_N = 0, \quad b_{N-1} = 2Na_n,
\]

and

\[
b_{k+2} - b_k = \frac{1}{c_{k+2}} 2(k + 1)a_{k+1}.
\]

Then we solve, in the physical space,

\[
\frac{\partial u_N}{\partial t}(x_j, t) = S(x_j) \frac{\partial u_N}{\partial x}(x_j, t), \quad j = 1, \ldots, N,
\]

\[
u_N(1, t) = 0.
\]

A very efficient time-marching technique which is explicit and unconditionally stable has been developed in [3] and can be used for the solution of (3.6).

The second way of collocation is carried out as follows. Set

\[
v_N(x_n, t) = \sum_{k=0}^{N-1} d_k T_k(x_n), \quad n = 0, \ldots, N - 1, x_n = \cos \frac{\pi n}{N}.
\]

It can be shown that \( d_k \) can be expressed in terms of \( a_k \) derived in (3.3). In fact

\[
d_k = a_k + (-1)^{N-1}2a_N(-1)^k/c_k.
\]

Equation (3.8) is derived as follows:

\[
u_N(x_n, t) = \sum_{k=0}^{N-1} a_k T_k(x_n) + a_N T_N(x_n)
\]

\[
= \sum_{k=0}^{N-1} a_k T_k(x_n) + (-1)^{N-1}2a_N \left[ \sum_{k=0}^{N-1} \frac{(-1)^k}{c_k} T_k(x_n) - \frac{(-1)^N}{c_N} T_N(x_n) \right]
\]

\[
= \sum_{k=0}^{N-1} a_k T_k(x_n) + (-1)^{N-1}2a_N \sum_{k=0}^{N-1} \frac{(-1)^k}{c_k} T_k(x_n) = \sum_{k=0}^{N-1} d_k T_k(x_n),
\]

for \( n = 0, \ldots, N - 1 \).

Now

\[
\frac{\partial v_N}{\partial x}(x_n, t) = \sum_{k=0}^{N-1} \gamma_k T_k(x_n),
\]

where

\[
\gamma_k = \frac{1}{c_k} \sum_{k=p+1}^{N} 2pd_p,
\]

and we solve

\[
\frac{\partial v_N(x_j, t)}{\partial t} = S(x_n) \frac{\partial v_N(x_j, t)}{\partial x}, \quad j = 1, \ldots, N - 1,
\]

\[
v_N(x_0, t) = 0.
\]

Observe that \( u_N \) in the second way of collocation (3.7)-(3.10) is a polynomial of degree \( N - 1 \), whereas in (3.2)-(3.6) it is a polynomial of degree \( N \). The similarity
between these two different methods can be seen in the case where \( S(x) = 1 \). Since 
\[
\frac{\partial u_N}{\partial t} - \frac{\partial u_N}{\partial x} = \text{a polynomial of degree } N \text{ that vanishes at } x = -1 \text{ and at the zeroes of } T'_N(x),
\]
we get
\[
(3.11a) \quad \frac{\partial u_N}{\partial t} = \frac{\partial u_N}{\partial x} + \tau_1(1 + x)T'_N(x)
\]
and, by the same argument,
\[
(3.11b) \quad \frac{\partial v_N}{\partial t} = \frac{\partial v_N}{\partial x} + \tau_2T'_N(x).
\]
It is interesting to note that for the Tau method one gets the error equation
\[
(3.12) \quad \frac{\partial R_N}{\partial t} = \frac{\partial R_N}{\partial x} + \tau_3T_N(x),
\]
where \( R_N \) is the Tau approximation to \( u \). It seems that the Tau method can be viewed, in the case of the constant coefficient problem (3.12), as a collocation method based on the collocation points
\[
(3.12a) \quad z_k = \cos\left(\frac{\pi}{2} \frac{2k - 1}{N}\right), \quad k = 1, \ldots, N.
\]
This observation suggests a convenient way of using the Tau method for the variable coefficient case as well; namely, set
\[
(3.13) \quad \frac{\partial R_N}{\partial t} - S(x) \frac{\partial R_N}{\partial x} = 0, \quad x = z_k, \quad k = 1, \ldots, N.
\]
This method reduces in the constant coefficient case to the Tau method. In order to establish stability for the collocation method described in (3.7)–(3.10), we need the following

**Lemma.** Let \( x_k = \cos \frac{\pi k}{N}, k = 0, \ldots, N - 1 \), then the quadrature formula
\[
(3.14) \quad \int_{-1}^{1} \sqrt{\frac{1 + x}{1 - x}} f(x) dx = \sum_{k=0}^{N-1} f(x_k) \hat{w}_k,
\]
where
\[
\hat{w}_k = \frac{1}{(1 - x_k)^2} \int_{-1}^{1} \frac{Y_{N-1}^2(x)}{(x - x_k)^2} \left(1 + x \right) dx > 0,
\]
\[
\hat{w}_0 = \frac{1}{Y_{N-1}^2(1)} \int_{-1}^{1} \frac{Y_{N-1}^2(x)}{1 - x} \left(1 + x \right) dx > 0
\]
is correct for every polynomial of degree \( 2N - 2 \) or less.

**Proof.** Let \( f(x) \) be a polynomial of degree \( 2N - 2 \). Set \( g(x) = (1 + x)f(x) \). Since \( g(x) \) is a polynomial of degree \( 2N - 1 \), formula (2.7) is exact.
\[
(3.15) \quad \int_{-1}^{1} \frac{(1 + x)f(x)}{\sqrt{1 - x^2}} dx = \sum_{j=0}^{N} (1 + x_j) w_j f(x_j) = \sum_{j=0}^{N-1} (1 + x_j) w_j f(x_j).
\]
Equation (3.15) implies (3.14) and \( w_k \) can be derived by a standard argument.

Now let \( v_N \) be the collocation approximation to \( u \), obtained by (3.7)–(3.10). Then
\[
(3.16) \quad \frac{\partial u_n}{\partial t} = S(x) \frac{\partial v_N}{\partial x}, \quad x = x_n, n = 1, \ldots, N - 1.
\]
Multiplying by \( v_N(x_n) \tilde{w}_n / c(x_n) \), we get from (3.16)
\[
\sum_{n=0}^{N-1} v_N(x_n) \frac{\partial v_N}{\partial t}(x_n) \frac{\tilde{w}_n}{S(x_n)} = \sum_{n=0}^{N-1} v_N(x_n) \frac{\partial v_N}{\partial x}(x_n) \tilde{w}_n
\]
and by (3.14)
\[
\int_{-1}^{1} \sqrt{\frac{1 + x}{1 - x}} v_N \frac{\partial u_N}{\partial x} \, dx
\]
(3.17)
\[
\leq \frac{1}{2} \sqrt{\frac{1 + x}{1 - x}} v_N^2 \left|_{-1}^{1} - \frac{1}{2} \int_{-1}^{1} \frac{v_N^2}{(1 - x) \sqrt{1 - x^2}} \, dx.
\]

The boundary term in the right-hand side of (3.17) vanishes since \( v_N(1) = 0 \) and \( v_N \) is a polynomial and therefore
\[
\frac{d}{dt} \sum_{n=0}^{N-1} v_N^2(x_n) \frac{\tilde{w}_n}{S(x_n)} < 0
\]
(3.18)
or
\[
\sum_{n=0}^{N-1} v_N^2(x_n, t) \frac{\tilde{w}_n}{S(x_n)} < \sum_{n=0}^{N-1} v_N^2(x_n, 0) \frac{\tilde{w}_n}{S(x_n)}.
\]

From the definition of \( w_n \) it follows that the norm described by the weights \( \tilde{w}_n / S(x_n) \) is algebraically equivalent to the norm in which we have consistency, therefore algebraic stability is proved. The same idea can be utilized in showing the stability of the Tau method. In fact, from (3.12) it is evident that
\[
\sum_{j=1}^{N} \frac{y_j}{1 - z_j} R_N(z_j) \frac{\partial R_N}{\partial t}(z_j) = \sum_{j=1}^{N} \frac{y_j}{1 - z_j} R_N(z_j) \frac{\partial R_N}{\partial x}(1 + z_j),
\]
(3.19)
where \( y_j \) are the weights in the Gauss-Chebyshev integration. From (3.17) it follows that
\[
\frac{d}{dt} \sum_{j=1}^{N} \frac{y_j}{1 - z_j} R_N^2(z_j, t) = \int_{-1}^{1} R_N \frac{\partial R_N}{\partial x} \frac{1 + x}{\sqrt{1 - x^2}} \, dx
\]
(3.20)
\[
= - \int_{-1}^{1} \frac{R_N^2}{(1 - x)^2} \frac{1}{\sqrt{1 - x^2}} \, dx < 0,
\]
which proves algebraic stability.

The stability of the collocation method described by (3.3)–(3.6) follows immediately from that described in (3.7)–(3.10). It can be seen from the relation (3.8). In fact, setting
\[
\frac{\partial u_N}{\partial t} - \frac{\partial u_N}{\partial x} = (1 + x) \left( \frac{\partial w_N}{\partial t} - \frac{\partial w_N}{\partial x} \right),
\]
one gets (3.11a) from (3.11b). This completes the discussion of collocation method for scalar equations. We refer the reader to [4] in which proper ways of implementing spectral methods for systems is discussed.
4. The proofs presented in the last section were confined to the case in which $S(x)$ does not change sign. This might be a weakness of the theory rather than that of the collocation method. Numerical experiments using the pseudospectral methods have indicated that there is no instability, that is they show the solution does not grow with $N$ even when $S(x)$ changes sign. There might be problems owing to growth in time of the solution or to the existence of a stationary characteristic in the neighborhood of either the boundary or some interior point. But these problems seem to occur because of lack of spatial resolution and not because of stability. In order to illustrate this fact let us consider two equations:

\begin{align}
(4.1) & \quad u_t = -xu_x, \quad |x| < 1, \\
& \quad u(x, 0) = f(x),
\end{align}

and

\begin{align}
(4.2) & \quad u_t = xu_x, \quad |x| < 1, \\
& \quad u(x, 0) = f(x), \quad u(\pm 1, t) = 0.
\end{align}

We attempt to solve (4.1) and (4.2) by the Chebyshev collocation method. According to the popular belief, there should be instabilities in the solution since $x$ changes sign in the domain. However, as indicated in Table I below no such instabilities were found. As a matter of fact, we can prove the following

**THEOREM.** The Chebyshev collocation method for (4.1) is stable.

**Proof.** Let $u_N$ be the Chebyshev approximation to $u$, obtained by the collocation method. Then

\begin{align}
(4.3a) & \quad \frac{\partial u_N}{\partial t} + x \frac{\partial u_N}{\partial x} = 0, \quad x = \cos \frac{\pi j}{N}, j = 0, \ldots, N, \\
\end{align}

as in (3.2). Or

\begin{align}
(4.3b) & \quad \frac{\partial v_N}{\partial t} + x \frac{\partial v_N}{\partial x} = 0, \quad x = \cos \frac{\pi j}{N}, j = 1, \ldots, N - 1, \\
\end{align}

as in (3.7). Since $u_N$ is $N$th degree polynomial and $v_N$ is $N - 1$ degree polynomial, we get

\begin{align}
(4.4) & \quad \frac{\partial w_N}{\partial t} = -x \frac{\partial w_N}{\partial x}, \quad -1 < x < 1,
\end{align}

where $w$ is either $u_N$ or $v_N$.

We now refer the reader to [1, pp. 85–87] for the proof that (4.4) implies stability.

**THEOREM.** The Chebyshev collocation approximation for (4.2) is stable.

**Proof.** Now $u_N$ satisfies

\begin{align}
(4.5) & \quad \frac{\partial u_N}{\partial t} = x \frac{\partial u_N}{\partial x}, \quad x = \cos \frac{\pi j}{N}, j = 1, \ldots, N - 1, \\
& \quad u_N(\pm 1, t) = 0.
\end{align}

Note that (4.5) has boundary conditions in contrast to (4.4). Let $w_j$ be defined in (2.7). From (4.5) it is clear that
\[
\sum_{j=0}^{N-1} \frac{u_N(x_j)}{1 + x_j} \frac{\partial u_N}{\partial t}(x_j)w_j = \sum_{j=0}^{N-1} \frac{x_j}{1 + x_j} u_N(x_j) \frac{\partial u_N}{\partial x}(x_j)w_j
\]

\[
= \sum_{j=0}^{N} \frac{x_j}{1 + x_j} u_N(x_j) \frac{\partial u_N}{\partial x}(x_j)w_j - \left( \frac{\partial u_N}{\partial x}(-1) \right)^2
\]

\[
< \int \frac{x}{(1 + x)\sqrt{1 - x^2}} u_N \frac{\partial u_N}{\partial x} \, dx
\]

\[
= -\int \frac{u_N^2}{(1 + x)^{5/2}(1 - x)^{3/2}} (1 - x + x^2) < 0
\]

and that proves stability.

It goes without saying that the proofs of the last two theorems can be extended to all the functions \(S(x)\) such that \(S(x)/x\) is of constant sign. We conjecture that it is true for any \(S(x)\).

In Table I we show the results of applying the Chebyshev-pseudospectral method to four equations.

</tbody>
</table>

The first equation is

(4.6a) \(u_t = (1 + x)u_x, \quad |x| < 1, \quad u(x, 0) = \sin \pi x, \quad u(1, t) = \sin(2e^t - 1)\pi\).

The solution to this problem is

(4.6b) \(u(x, t) = \sin \pi [(1 + x)e^t - 1]\).

This problem has a characteristic boundary at \(x = -1\). Moreover, for large \(t\) the solution has a large variation in the neighborhood of \(x = -1\).

The second problem is

(4.7a) \(u_t = (1 - x)u_x, \quad u(x, 0) = \sin \pi x\).

The solution is given by

(4.7b) \(u(x, t) = \sin \pi [1 - (1 - x)e^{-t}]\).

The line \(x = 1\) is a characteristic boundary, but, in contrast to the equation (4.6), the neighboring characteristics point from the boundary towards the domain. The third is

(4.8a) \(u_t = xu_x, \quad u(x, 0) = \sin \pi x, \quad u(1, t) = \sin(\pi e^t), \quad u(-1, t) = -\sin(\pi e^t).\)

The solution is

(4.8b) \(u(x, t) = \sin(\pi xe^t)\).
And the fourth is

\[(4.9a) \quad u_t = -xu_x, \quad u(x, 0) = \sin \pi x,\]

where

\[(4.9b) \quad u(x, t) = \sin(\pi x e^{-t}).\]

All these problems were solved by Chebyshev-pseudospectral methods with the modified Euler time-marching techniques. With the time step \(\Delta t = 1/\Delta x_{\min}\), we advance from the time 0 to the time \(t = 2\). Note that since \(x_N - x_{N-1} = O(1/N^2)\), then \(\Delta x_{\min} \sim O(1/N^2)\).

In Table I we show the \(L_2\) Chebyshev errors of the solution of the problems (4.6)–(4.9). It is clear that the Chebyshev collocation method is stable for all these problems and has the same rate of convergence. However, the errors for problems (4.6) and (4.8) were much larger than those of (4.7) and (4.9). In fact taking 64 modes in the solution of (4.6) and (4.8) produce the same error that 17 modes produce for (4.6) and (4.8). This is a problem of accuracy and not of stability. The question now is, do we retain spectral accuracy? To answer this question we ran the problem (4.8) with smaller and smaller time steps until the results were not changed, which means that we were limited only by the space accuracy. For 17 modes we got an \(L_2\) error of \(1.16 \cdot 10^{-1}\), whereas for 33 modes and the fine time step we got an error of \(6 \cdot 10^{-5}\). This indicates that the order of accuracy in space is indeed better than any algebraic order.

**Conclusion.** It has been shown in this paper that the pseudospectral-Chebyshev methods are convergent in variable coefficient parabolic problems and in some cases to hyperbolic problems. The analysis shows that the rate of convergence is greater for finite difference methods or the finite element method. It seems that for a single first-order hyperbolic equation the method remains stable even when the coefficient changes sign, though in this case care must be taken to have adequate spatial resolution. This fact, combined with the fact that collocation methods are easy to apply in the nonlinear case, shows that the pseudospectral method is in general preferable to Galerkin or Tau methods.
