On a Dimensional Reduction Method.

III. A Posteriori Error Estimation and an Adaptive Approach*

By M. Vogelius and I. Babuška

Abstract. This paper is the last in a series of three which analyze an adaptive approximate approach for solving \((n + 1)\)-dimensional boundary value problems by replacing them with systems of equations in \(n\)-dimensional space.

In this paper we show how to find reliable a posteriori estimates for the error and how these can also be used in the design of an adaptive strategy. Various numerical examples are contained in the paper.

1. Introduction. In a recent paper, [6], we introduced the concept of dimensionally reduced solutions to an elliptic boundary value problem. These are obtained by projecting (in the energy) the true solution of the boundary value problem in the \((n + 1)\)-dimensional domain \(\omega \times [-h, h]\) onto spaces of the form

\[
V^h_N = \left\{ \sum_{j=0}^{N} w_j(x) \psi_j(y/h) | w_j \text{ arbitrary} \right\},
\]

where \(\{\psi_j\}_{j=0}^{\infty}\) is a given set of functions on \([-1, 1]\), \(x\) are coordinates on \(\omega\) and \(y\) ranges over \([-h, h]\). For some basic ideas behind this concept, see [6] and the introduction to [5]. In [6] the focus was on the right selection of the \(\psi_j\)'s. It was shown there that for a very wide class of problems the \(\psi_j\)'s should be selected such that

\[
\text{span}\{\psi_j\}_{j=0}^{2k-1} = \mathcal{R}(P^k),
\]

where \(P\) is a second order ordinary differential operator intrinsic to the elliptic boundary value problem.

In [7] we analyzed the convergence properties of such methods as the order, \(N\), increases.

The present paper, which is a direct continuation of the previous work, deals with the problem of reliable a posteriori error estimation. It also designs an adaptive algorithm for the selection of the right dimensionally reduced solution. As it follows from [6] and [7], a high number of basis functions \(\psi_j\) may be needed (depending on the desired accuracy) either if the thickness of the domain, \(h\), is not
sufficiently small or there are singularities in the true solution to the boundary value problem. (Because of the corner in the domain such singularities are often present in the neighborhood of \( \partial \omega \times \{-h\} \) and \( \partial \omega \times \{h\} \).)

Since singularities are local phenomena, it is of the utmost practical importance to introduce dimensionally reduced solutions that permit \( N \), the order, to vary throughout the domain \( \omega \). This aspect, specifically the adaptive choice of the distribution for \( N \), is also addressed here.

We now give a short review of the contents of this paper.

In Section 2 we give a precise formulation of the model problem (which is identical to that of [6]) and prove some auxiliary results.

Section 3 is devoted to the construction of an estimator for the error. The main theoretical results in this section are Theorem 3.1 and Theorem 3.2, which show that the introduced estimator is an upper bound for the error but on the other hand is not too conservative (away from singularities and for reasonably small \( h \)). Numerical experiments verify this and furthermore indicate that even for relatively large \( h \), or strong singularities, the estimator is of the same magnitude as the error. The problems of how to detect if the estimator is unacceptably conservative and how to improve it are addressed in Section 4.

In Section 5 we extend the concept of dimensional reduction to include a possibly different number of basis functions, \( \psi_j \), in different parts of the domain. We also design an adaptive strategy to select the right distribution for the number of basis functions. This strategy is based on our ability to give reliable estimates for the error much in the same way as the strategy used by the finite element solver F.E.A.R.S. to generate an 'optimal' grid; cf. [1].

Finally Section 6 (and also 4) contains a numerical example that illustrates how well the error estimation and the adaptive strategy perform in practice.

2. Notation and the Model Problem. Let \( \mathcal{K} \) be a separable Hilbert space with inner product \( \langle u, v \rangle \) and norm \( \|u\| = \langle u, u \rangle^{1/2} \).

\( A \) denotes a (possibly unbounded) selfadjoint linear operator in \( \mathcal{K} \) with domain of definition \( \mathcal{D}(A) \).

Furthermore, we assume that \( A \) is a strictly positive-definite operator, i.e., there exists \( C > 0 \) such that

\[ \forall u \in \mathcal{D}(A): \ C\|u\|^2 < \langle Au, u \rangle. \]

Let \( M \) be a selfadjoint bounded linear operator in \( \mathcal{K} \). \( M \) is also assumed to be a strictly positive-definite operator.

\( \mathcal{D}(A^{1/2}) \) is itself a Hilbert space with inner product \( \langle u, v \rangle + \langle A^{1/2}u, A^{1/2}v \rangle \).

The same is true about \( \mathcal{D}((M^{-1}A)^k) \) for any integer \( k > 0 \).

\( I \) denotes an interval on the real line. \( L^2(I; \mathcal{K}) \) is defined as the set of strongly measurable functions \( u: I \to \mathcal{K} \) such that \( \|u(\cdot)\| \) is an element of \( L^2(I) \); cf. [4]. The same goes for \( L^2(I; \mathcal{D}(A^{1/2})) \) and \( L^2(I; \mathcal{D}((M^{-1}A)^k)). \)

We also need Sobolev spaces of functions with values in \( \mathcal{K} \), \( \mathcal{D}(A^{1/2}) \) and \( \mathcal{D}((M^{-1}A)^k) \). \( H^1(I; \mathcal{K}) \) denotes the space of functions \( u: I \to \mathcal{K} \) such that \( u(\cdot) \in L^2(I; \mathcal{K}) \) and \( (d/d\gamma)u(\cdot) \in L^2(I; \mathcal{K}); \) cf. [2]. The spaces for \( \mathcal{D}(A^{1/2}) \) and \( \mathcal{D}((M^{-1}A)^k) \) are defined similarly. The derivative is taken in the distributional sense.
$H^1(I)$ denotes the standard Sobolev space on $I$.

Assume $a$ and $b$ are real valued functions in $L^\infty([-1, 1])$ such that

$$a_0 < a(y), \quad b_0 < b(y)$$

for some constants $a_0 > 0, b_0 > 0$. $a_h$ and $b_h \in L^\infty([-h, h])$ are then defined as

$$a_h(y) = a(y/h), \quad b_h(y) = b(y/h).$$

By $P_h(d/dy)$ we denote the differential operator $-(d/dy)(a_h d/dy)$. Let $f$ and $g$ be two arbitrary vectors from $\mathcal{C}$. We consider the following model problem

$$P_h Mu + b_h Au = 0 \quad \text{in} \quad [-h, h [,$$

$$a_h \frac{d}{dy} Mu = g \quad \text{for} \quad y = h,$$

$$b_h \frac{d}{dy} Mu = f \quad \text{for} \quad y = -h.$$  

(1)

The precise formulation of (1) is

$$u^h \in H^1([-h, h]; \mathcal{C}) \cap L^2([-h, h]; \mathcal{D}(A^{1/2})),

$$\mathfrak{B}_h(u, v) = \langle g, v(h) \rangle - \langle f, v(-h) \rangle,

$$\forall \ v \in H^1([-h, h]; \mathcal{C}) \cap L^2([-h, h]; \mathcal{D}(A^{1/2})),

(2)

where $\mathfrak{B}_h$ denotes the bilinear form

$$\mathfrak{B}_h(u, v) = \int_{-h}^{h} a_{1/2} \left( M_{1/2} \frac{d}{dy} u, M_{1/2} \frac{d}{dy} v \right) \ dy + \int_{-h}^{h} b_{1/2} \left( A_{1/2} u, A_{1/2} v \right) \ dy.$$

For more details, see [6]. In that paper we introduced the notion of dimensionally reduced solutions to (1). Let $\{\psi_j\}_{j=0}^{\infty} \subset H^1([-1, 1])$ be a given sequence of linearly independent functions (referred to as basis functions).

Definition. The dimensionally reduced solution $u_N^h$ of order $N$ is the projection of $u^h$ onto the space

$$V_N^h = \left\{ \sum_{j=0}^{N} \psi_j(y/h)x_j \mid x_j \in \mathcal{D}(A^{1/2}), \ j = 0, \ldots, N \right\}.$$

The projection is with respect to the inner product $\mathfrak{B}_h(u, v)$.

We proved that in order to obtain optimal rate error estimates for $h \to 0$ there is essentially only one choice for the sequence $\{\psi_j\}_{j=0}^{\infty}$. This is related to the operator $P = b^{-1}(d/dy)(a d/dy)$.

**THEOREM.** There exists a sequence of linearly independent functions $\{\psi_j\}_{j=0}^{\infty}$, with

(i) $\mathfrak{R}(P^i) = \text{span}\{\psi_j\}_{j=0}^{2i-1}, \ i > 1,$

that has the following property:

(ii) For any integer $N > 0$ and for any given set of vectors $f, g \in \mathcal{D}((AM^{-1})^N)$ there exists a constant $C_N$ (independent of $h$) such that

$$\| u^h - u_N^h \|_E \leq C_N h^{2N+1/2}.$$

$\mathfrak{R}(P^i)$ here denotes the nullspace of $P^i$, and $\| \cdot \|_E$ is the energy-norm associated with the bilinear form $\mathfrak{B}_h$. This is slightly different from the formulation in [6],
where we used the norm
\[
\left( \int_{-h}^{h} \left| \frac{d}{dy} u(y) \right|^2 dy + \int_{-h}^{h} \| A^{1/2} u(y) \|^2 dy \right)^{1/2}.
\]

It is obvious though, that these two norms are equivalent with constants independent of \( h \). For more details concerning this theorem and its converse we refer to [6].

It is now convenient to introduce

**Definition.** Any sequence \( \{ \psi_j \}_{j=0}^{\infty} \) that has the two properties listed in the previous theorem is said to be an optimal sequence of basis functions.

It follows immediately from Theorem 4.1 of [6] that any two optimal sequences of basis functions \( \{ \phi_j \}_{j=0}^{\infty} \) and \( \{ \psi_j \}_{j=0}^{\infty} \) satisfy
\[
\text{span}\{ \phi_j \}_{j=0}^{N} = \text{span}\{ \psi_j \}_{j=0}^{N} \quad \forall \ N > 0.
\]

We shall often use this fact without explicitly mentioning so.

In the present paper we need a slightly different but weaker version of the result contained in Theorem 4.1 of [6].

**Lemma 2.1.** Let \( \{ \psi_j \}_{j=0}^{\infty} \) be an optimal sequence of basis functions, and let \( N \) be an integer \( \geq 0 \).

For any nontrivial set of vectors \( f, g \in \mathcal{X} \), there exists a constant \( C_N \) (independent of \( h \)) such that
\[
C_N h^{2N+1/2} < \left\| u^h - u_{2N}^h \right\|_E
\]
for \( h \) sufficiently small.

**Proof.** The proof is by contradiction, i.e., we assume
\[
\left\| u^h - u_{2N}^h \right\|_E = o(h^{2N+1/2})
\]
for some sequence \( h_i \), with \( h_i \to 0 \) as \( i \to \infty \).

If \( f \) and \( g \) are linearly independent, Theorem 4.1 of [6] then gives that
\[
\text{span}\{ \psi_j \}_{j=0}^{2N+2} \subseteq \text{span}\{ \psi_j \}_{j=0}^{2N},
\]
and this is obviously a contradiction.

We therefore only have to consider the case when \( f \) and \( g \) are linearly dependent, say \( f = \alpha \cdot g, g \neq 0 \). As in the proof of Theorem 4.1 of [6] it now follows that
\[
\frac{d}{dy} \psi_j^{0} + 1 - \alpha \frac{d}{dy} \psi_j^{1} \in \text{span}\left\{ \frac{d}{dy} \psi_j \right\}_{j=0}^{2N},
\]
where \( \psi_j^{0} \) and \( \psi_j^{1} \) are as introduced in Lemma 3.1 of [6]. Since
\[
\text{span}\left\{ \frac{d}{dy} \psi_j \right\}_{j=0}^{2N} = \text{span}\left\{ \frac{d}{dy} \psi_j^{0}, \frac{d}{dy} \psi_j^{1} \right\}_{j=0}^{2N}
\]
and
\[
b^{-1} \frac{d}{dy} a \frac{d}{dy} \psi_j^{l} = \psi_j^{l-1}, \quad l = 0, 1,
\]
(3) immediately leads to the conclusion
\[
\psi_j^{0} - \alpha \psi_j^{1} \in \text{span}\{ \psi_j^{0}, \psi_j^{1} \}.
\]
Because of the fact that $\psi_0^0$ and $\psi_1^1$ are both constant, we get

$$\frac{d}{dy} \psi_0^0 - \alpha \frac{d}{dy} \psi_1^1 = 0.$$ \hfill (4)

But, according to [6], $\psi_0^0$ and $\psi_1^1$ satisfy

$$a \frac{d}{dy} \psi_0^0(1) = 1, \quad a \frac{d}{dy} \psi_1^1(1) = 0,$$

so (4) is obviously a contradiction. \[\square\]

For the analysis in this paper we also need two simple regularity results, one concerning the true solution $u^h$ and one concerning the dimensionally reduced solutions $u^h_N$.

**Lemma 2.2.** Let $u^h$ denote the solution to (2). If for some integer $k > 0$, $f, g \in \mathcal{D}((AM^{-1})^k)$, then

$$u^h \in H^1([-h, h]; \mathcal{D}((M^{-1}A)^k)) \cap L^2([-h, h]; \mathcal{D}(A^{1/2}(M^{-1}A)^k))$$

**Proof.** Let $\tilde{u}^h$ denote the solution to (2) in the case where $f$ and $g$ have been replaced by $(AM^{-1})^k f$ and $(AM^{-1})^k g$, respectively, i.e.,

$$\mathcal{B}_h(\tilde{u}^h, v) = \langle (AM^{-1})^k g, v(h) \rangle - \langle (AM^{-1})^k f, v(-h) \rangle$$

$$\forall v \in H^1([-h, h]; \mathcal{K}) \cap L^2([-h, h]; \mathcal{D}(A^{1/2}))$$

We then get that

$$\mathcal{B}_h((AM^{-1})^k \tilde{u}^h, v) = \mathcal{B}_h(\tilde{u}^h, (AM^{-1})^k v) = \langle (AM^{-1})^k g, (AM^{-1})^k v(h) \rangle$$

$$-\langle (AM^{-1})^k f, (AM^{-1})^k v(-h) \rangle$$

$$= \langle g, v(h) \rangle - \langle f, v(-h) \rangle$$

$$\forall v \in H^1([-h, h]; \mathcal{K}) \cap L^2([-h, h]; \mathcal{D}(A^{1/2}))$$

and hence $(AM^{-1})^k \tilde{u}^h = u^h$. Since $\tilde{u}^h \in H^1([-h, h]; \mathcal{K}) \cap L^2([-h, h]; \mathcal{D}(A^{1/2}))$, the desired result now immediately follows. \[\square\]

The regularity result we need for the dimensionally reduced solutions $u^h_N$ is the following.

**Lemma 2.3.** Let $u^h_N = \sum_{j=0}^N \psi_j(y/h)x_j$ denote a dimensionally reduced solution of order $N$. If, for some integer $k > 0, f, g \in \mathcal{D}((AM^{-1})^k)$, then

$$x_j \in \mathcal{D}((M^{-1}A)^{k+1}) \quad \forall j: 0 < j < N.$$ 

**Proof.** Let $x \in \mathcal{K}^{N+1}$ denote the vector $(x_0, \ldots, x_N)$. It is clear that $x$ is the solution to

$$h\langle CA^{1/2}x, A^{1/2}y \rangle + h^{-1}\langle DM^{1/2}x, M^{1/2}y \rangle = \langle r, y \rangle$$

$$\forall y \in \mathcal{D}(A^{1/2})^{N+1},$$

where $C = \{c_{ij}\}_{i,j=0}^N$, $D = \{d_{ij}\}_{i,j=0}^N$, and $r = \{r_i\}_{i=0}^N$ are given by

$$c_{ij} = \int_{-1}^1 \psi_j(y)\psi_i(y) \, dy, \quad d_{ij} = \int_{-1}^1 \left( \frac{d}{dy} \psi_i \right) \left( \frac{d}{dy} \psi_j \right) \, dy,$$

and $r_i = \psi_i(1)g - \psi_i(-1)f$, respectively. (We have here used $\langle \cdot, \cdot \rangle$ also to denote the inner product $\sum_{i=0}^N \langle x_i, y_i \rangle$ in $\mathcal{K}^{N+1}$.)
Due to the fact that $A$ is selfadjoint and $M$ bounded, we get that $x \in [\mathcal{D}(A)]^{N+1}$ and
\[ hCAx + h^{-1}DMx = r, \quad \text{i.e.,} \quad Ax = h^{-1}C^{-1}r - h^{-2}C^{-1}DMx. \]

By successive application of this equality it follows that $r \in [\mathcal{D}((AM^{-1})^{N+1})]$ implies $x \in [\mathcal{D}((M^{-1}A)^{k+1})]^{N+1}$. This finishes the proof of the lemma. $\square$

3. A Posteriori Error Estimation in the General Case. As already mentioned in the introduction, one purpose of this paper is to derive a reliable technique for a posteriori estimation of the error introduced by dimensional reduction. The error here is measured in the energy-norm. The key ingredient of this technique is a so-called estimator $\text{Est}$, which we now proceed to define.

Let $\epsilon \in H^{1}([-h, h]; \mathfrak{K})$ be the solution to
\[
\begin{align*}
\left(\begin{array}{c}
P_h \left( \frac{d}{dy} \right) M \epsilon = -P_h \left( \frac{d}{dy} \right) M u_N^h - b_h A u_N^h \\
ap_h \frac{d}{dy} M \epsilon = g - a_h \frac{d}{dy} M u_N^h \\
ap_h \frac{d}{dy} M \epsilon = f - a_h \frac{d}{dy} M u_N^h
\end{array}\right) \quad \text{in } ]-h, h[, \\
\text{for } y = h, \\
\text{for } y = -h.
\end{align*}
\]

The exact meaning of (5) is
\[
\begin{align*}
\epsilon \in H^{1}([-h, h]; \mathfrak{K}) \quad \text{and} \\
\int_{-h}^{h} a_h \left( M^{1/2} \frac{d}{dy} \epsilon, M^{1/2} \frac{d}{dy} v \right) dy = \langle g, v(h) \rangle - \langle f, v(-h) \rangle \\
- \int_{-h}^{h} a_h \left( M^{1/2} \frac{d}{dy} u_N^h, M^{1/2} \frac{d}{dy} v \right) dy = - \int_{-h}^{h} b_h \langle A u_N^h, v \rangle dy \\
\forall \ v \in H^{1}([-h, h]; \mathfrak{K}).
\end{align*}
\]

In Eqs. (5) and (6) we have used the fact that $u_N^h(y) \in \mathcal{D}(A)$, which immediately follows from Lemma 2.3 with $k = 0$.

Since (6) is a Neuman problem for $\epsilon$, it only has a solution provided
\[
\langle g, \epsilon \rangle - \langle f, \epsilon \rangle - \int_{-h}^{h} b_h \langle A u_N^h, \epsilon \rangle dy = 0 \quad \forall \ x \in \mathfrak{K}.
\]

Because of the equations defining $u_N^h$, it follows that this is true if
\[
1 \in \text{span}\{\psi_j\}_{j=0}^N.
\]

Note. According to Theorems 3.1 and 4.1 of [6], condition (7) is in general necessary and always sufficient to ensure that
\[
\|u^h - u_N^h\|_{E} \to 0 \quad \text{for } h \to 0.
\]

Certainly (7) is satisfied for any optimal sequence of basis functions.

We now define
\[
\text{Est} = \left( \int_{-h}^{h} a_h \left\| M^{1/2} \frac{d}{dy} \epsilon \right\|^2 dy \right)^{1/2}.
\]
The function $e$ is clearly not uniquely determined, but, since only $de/dy$ is involved, $E_{st}$ is well-defined. We shall now show that the estimator $E_{st}$ exhibits some very attractive properties.

**Theorem 3.1.** Let $u^h$ be the solution to (2) and $u^h_{N}$ a dimensionally reduced solution of order $N > 0$ corresponding to a sequence of basis functions that satisfies (7). If $E_{st}$ is as defined in (8), then

$$||u^h - u^h_{N}||_{E} < E_{st}.$$ 

**Note.** In the terminology of [1] this theorem says that $E_{st}$ is a 'guaranteed' upper estimator.

**Proof.** Clearly

$$||u^h - u^h_{N}||_{E} = \sup |\mathcal{B}_{h}(u^h - u^h_{N}, v)|/||v||_{E},$$

where the sup is taken over $v \in H^1([-h, h]; \mathcal{C}) \cap L^2([-h, h]; \mathcal{D}(A^{1/2}))$. According to the definition of $e$, this is nothing but

$$\sup |\int_{-h}^{h} a_h \left( M^{1/2} \frac{d}{dy} e, M^{1/2} \frac{d}{dy} v \right) dy|/||v||_{E},$$

and, using Schwarz's inequality, we now get

$$||u^h - u^h_{N}||_{E} < \left( \int_{-h}^{h} a_h \left| M^{1/2} \frac{d}{dy} e \right|^2 dy \right)^{1/2} = E_{st}. \quad \square$$

For use of the estimator $E_{st}$ in actual computations, it is important that it is very close to the real error in a wide class of situations. In the terminology of [1] this is expressed by the requirement that $E_{st}$ be asymptotically exact. The following theorem contains a precise formulation of the asymptotical exactness for the estimator $E_{st}$. It is essential here that the dimensional reduction is based on an optimal sequence of basis functions.

**Theorem 3.2.** Let $\{\psi_j\}_{j=0}^{\infty}$ be an optimal sequence of basis functions. Let $u^h$ be the solution to (2) and $u^h_{N}$ be the dimensionally reduced solution of order $N > 0$. Assume furthermore that $f$ and $g$ are elements of $\mathcal{D}(AM^{-1}(N+1)/2+1)$.

If $E_{st}$ is as defined in (8), then

$$E_{st} = ||u^h - u^h_{N}||_{E}(1 + O(h^2)).$$

**Note.** Here $[ \cdot ]$ denotes the integer part.

**Proof.** Since $f, g \in \mathcal{D}(AM^{-1})$, it follows from Lemma 2.3 and (5) that $e$ in this case can be selected so that $e \in H^1([-h, h]; \mathcal{D}(A))$. We now have

$$E_{st} = \left| \int_{-h}^{h} a_h \left( M^{1/2} \frac{d}{dy} e, M^{1/2} \frac{d}{dy} e \right) dy \right|/\left( \int_{-h}^{h} a_h \left| M^{1/2} \frac{d}{dy} e \right|^2 dy \right)^{1/2}$$

$$\leq \left( \sup |\int_{-h}^{h} a_h \left( M^{1/2} \frac{d}{dy} e, M^{1/2} \frac{d}{dy} v \right) dy|/||v||_{E} \right)$$

$$\cdot \left( ||e||_{E}/\left( \int_{-h}^{h} a_h \left| M^{1/2} \frac{d}{dy} e \right|^2 dy \right)^{1/2} \right).$$
where the sup is taken over 

\[ v \in H^1([-h, h]; \mathcal{C}) \cap L^2([-h, h]; \mathcal{D}(A^{1/2})) \]

As shown in the proof of Theorem 3.1, this last expression is equal to

\[
\| u^h - u_N^h \|_E \cdot \| \varepsilon \|_E / \left( \int_{-h}^{h} a_h \left\| M^{1/2} \frac{d}{dy} \varepsilon \right\|^2 dy \right)^{1/2} 
\]

The theorem will therefore be proven if we show that \( \varepsilon \) can be chosen such that

\[
\int_{-h}^{h} b_h \| A^{1/2} \varepsilon \|^2 dy < C_N h^2 \left( \int_{-h}^{h} a_h \left\| M^{1/2} \frac{d}{dy} \varepsilon \right\|^2 dy \right). 
\]

It is clear that, by appropriately selecting the undetermined constant of \( \varepsilon \), we can obtain

\[
\int_{-h}^{h} b_h \| A^{1/2} \varepsilon \|^2 dy < C h^2 \int_{-h}^{h} a_h \left\| M^{1/2} \frac{d}{dy} A^{1/2} \varepsilon \right\|^2 dy 
\]

(10)

\[
= C h^2 \int_{-h}^{h} a_h \left( \frac{d}{dy} \varepsilon, \frac{d}{dy} A \varepsilon \right) dy. 
\]

Now from (6), the definition of \( \varepsilon \), we have

\[
\int_{-h}^{h} a_h \left( \frac{d}{dy} \varepsilon, \frac{d}{dy} A \varepsilon \right) dy = \int_{-h}^{h} a_h \left( M^{1/2} \frac{d}{dy} \varepsilon, M^{1/2} \frac{d}{dy} M^{-1} A \varepsilon \right) dy 
\]

\[
= \langle g, M^{-1} A \varepsilon(h) \rangle - \langle f, M^{-1} A \varepsilon(-h) \rangle 
\]

\[
- \int_{-h}^{h} a_h \left( M^{1/2} \frac{d}{dy} u_N^h, M^{1/2} \frac{d}{dy} M^{-1} A \varepsilon \right) dy 
\]

\[
- \int_{-h}^{h} b_h \langle A u_N^h, M^{-1} A \varepsilon \rangle dy, 
\]

and by introduction of \( u^h \) this is, because of Lemma 2.3, equal to

\[
\mathcal{B}_h(M^{-1} A(u^h - u_N^h), \varepsilon). 
\]

By an application of Schwarz's inequality, this expression can be bounded by

\[
\| M^{-1} A(u^h - u_N^h) \|_E \cdot \| \varepsilon \|_E. 
\]

From the fact that \( A \) is strictly positive-definite together with (10), it follows that

\[
\| \varepsilon \|_E < C(1 + h^2) \left( \int_{-h}^{h} a_h \left\| M^{1/2} \frac{d}{dy} A^{1/2} \varepsilon \right\|^2 dy \right)^{1/2}, 
\]

and, since we only need to consider small \( h \), this now gives

\[
\int_{-h}^{h} a_h \left\| M^{1/2} \frac{d}{dy} A^{1/2} \varepsilon \right\|^2 dy = \mathcal{B}_h(M^{-1} A(u^h - u_N^h), \varepsilon) 
\]

\[
< C \| M^{-1} A(u^h - u_N^h) \|_E \left( \int_{-h}^{h} a_h \left\| M^{1/2} \frac{d}{dy} A^{1/2} \varepsilon \right\|^2 dy \right)^{1/2}. 
\]

By insertion in (10) we conclude that

(11)

\[
\int_{-h}^{h} b_h \| A^{1/2} \varepsilon \|^2 dy < C h^2 \| M^{-1} A(u^h - u_N^h) \|_E^2. 
\]

For the rest of this proof let us assume that \( N \) is even (the procedure for \( N \) odd is quite similar, only there are slight variations of Lemma 2.1 and Theorem 3.1 of [6] needed in this case).
It follows immediately from the proofs of Lemmas 2.2 and 2.3 that $M^{-1}Au^h$ and $M^{-1}A_N^h$ are solutions to the same problems as $u^h$ and $u_N^h$ just with $f$ and $g$ replaced by $AM^{-1}f$ and $AM^{-1}g$. Because of Theorem 3.1 in [6] and the assumption that $f, g \in O((AM^{-1})^{N/2+1})$, we get
\[ \|M^{-1}A(u^h - u_N^h)\|_E < C_N h^{N+1/2}, \]
and this combined with (11) immediately leads to
\[ \int_{-h}^h b_h A^{1/2} \| \|_{A}^2 \, dy < C_N h^{2N+3}. \]

On the other side from Lemma 2.1 it follows that
\[ C_N h^{2N+1} < \|u^h - u_N^h\|_E. \]
From the definition of Est and Theorem 3.1 of this paper, we therefore get
\[ C_N h^{2N+1} < \int_{-h}^h a_h M^{-1/2} \frac{d}{dy} \| \|_{A}^2 \, dy, \]
that is, we have finally proven
\[ \int_{-h}^h b_h A^{1/2} \| \|_{A}^2 \, dy < C_N h^2 \int_{-h}^h a_h M^{-1/2} \frac{d}{dy} \| \|_{A}^2 \, dy. \]

Since the estimator Est is to be used in actual computation, it is of the utmost importance that it can be calculated very simply. The equations (6) and (8) that include the solution of an O.D.E. are therefore not well suited as a formula for the calculation of Est. In the following we shall show how easily Est can be calculated by means of different formulae. For these formulae to be valid it is essential not only that the dimensional reduction is based on an optimal sequence of basis functions but also that this sequence satisfies a special orthogonality condition.

Let $\{\psi_j\}_{j=0}^\infty$ denote an optimal sequence of basis functions which is orthogonal in the semi-inner-product $\int_{-1}^1 ad/\,dy \cdot d/\,dy \cdot \,dy$. ($\psi_j$ is clearly uniquely determined modulo a constant and a scalar.)

We define a sequence $\{\phi_j\}_{j=0}^\infty$ by
\[ \phi_0 = 1, \]
\[ \phi_1(y) = \psi_1(y) - \left( \int_{-1}^1 b(t) \, dt \right)^{-1} \int_{-1}^1 b(t) \psi_1(t) \, dt \]
\[ \phi_j(y) = \psi_j(y) - \psi_j(-1) \quad \text{for } j \geq 2. \]
($\phi_j, j > 1$, are therefore uniquely determined modulo a scalar.)

**Lemma 3.1.** Let $\{\phi_j\}_{j=0}^\infty$ be a sequence as defined above. Let $u_N^h = \sum_{j=0}^N \phi_j(y/h) x_j$ denote the corresponding dimensionally reduced solution of order $N$. If $\varepsilon$ is as defined in (6), then there exist constants $\{c_k\}_{k=0}^\infty$ and $\{\tilde{c}_k\}_{k=0}^\infty$ such that
\[ \frac{d}{dy} \varepsilon = \left( \frac{d}{dy} \phi_1 \right) (y/h) M^{-1}(c_0(f + g) + \tilde{c}_0(f - g)) \]
\[ + \left( \frac{d}{dy} \phi_2 \right) (y/h) h M^{-1} A c_1 x_0 \quad \text{for } N = 0 \]
and

\[
\frac{d}{dy} \varepsilon = \left( \frac{d}{dy} \phi_{N+1} \right) \left( \frac{y}{h} \right) hM^{-1} A(eN_{N-1} + \varepsilon Nx_N) \\
+ \left( \frac{d}{dy} \phi_{N+2} \right) \left( \frac{y}{h} \right) hM^{-1} A_{N+1}x_N \quad \text{for } N > 1.
\]

**Proof.** Since \( \{\phi_j\}_{j=0}^\infty \) is an optimal sequence of basis functions, it follows immediately that

\[
\varepsilon = \sum_{j=0}^{N+2} \phi_j(y/h) \varepsilon_j
\]

for some \( \varepsilon_j \in \mathbb{C} \), \( 0 < j < N + 2 \), i.e.,

\[
\frac{d}{dy} \varepsilon = \sum_{j=1}^{N+2} h^{-1} \left( \frac{d}{dy} \phi_j \right)(y/h) \varepsilon_j.
\]

For any \( 1 < j < N \) and \( x \in \mathcal{O}(A^{1/2}) \),

\[
\langle Me_j, x \rangle \int_{-1}^{1} a \left( \frac{d}{dy} \phi_j \right)^2 \, dy = \langle M^{1/2} \varepsilon_j, M^{1/2} x \rangle h \int_{-h}^{h} a_h \left( \frac{d}{dy} \phi_j(y/h) \right)^2 \, dy
\]

\[
= h \int_{-h}^{h} a_h \left( M^{1/2} \frac{d}{dy} \varepsilon, M^{1/2} \frac{d}{dy} \phi_j(y/h)x \right) \, dy,
\]

where the last equality is due to the fact that \( \{\phi_j\}_{j=0}^\infty \) is orthogonal in the semi-inner-product \( \int_{-1}^{1} ad/\, dy \cdot d/\, dy \cdot dy \). Now from (6) we get that the last expression is equal to \( h \mathcal{O}_h(u^h - u_N^h, \phi_j(y/h)x) \), and this vanishes because \( u_N^h \) is defined as a projection. We have therefore proven that

\[
\langle Me_j, x \rangle = 0 \quad \forall 1 < j < N, x \in \mathcal{O}(A^{1/2}),
\]

or

(12) \[
\varepsilon_j = 0 \quad \forall 1 < j < N.
\]

For \( j = N + 1 \) we get as before

\[
\langle Me_{N+1}, x \rangle \int_{-1}^{1} a \left( \frac{d}{dy} \phi_{N+1} \right)^2 \, dy
\]

\[
= h \int_{-h}^{h} a_h \left( M^{1/2} \frac{d}{dy} \varepsilon, M^{1/2} \frac{d}{dy} \phi_{N+1}(y/h)x \right) \, dy,
\]

and this is, according to (6), equal to

\[
h \langle g, \phi_{N+1}(1)x \rangle - h \langle f, \phi_{N+1}(-1)x \rangle - h \int_{-h}^{h} b_h \langle Au_N^h, \phi_{N+1}(y/h)x \rangle \, dy.
\]

In this identity we also used the orthogonality of the \( \phi_j \)'s. Concerning the last term

\[
h \int_{-h}^{h} b_h \langle Au_N^h, \phi_{N+1}(y/h)x \rangle \, dy = h^2 \sum_{j=0}^{N} \langle Ax_j, x \rangle \int_{-1}^{1} b(y) \phi_j(y) \phi_{N+1}(y) \, dy.
\]

This vanishes for \( N = 0 \), because \( \int_{-1}^{1} b(y) \phi_1(y) \, dy = 0 \), and therefore establishes the formula for \( \varepsilon_{N+1} \) in the particular case \( N = 0 \).
In the following we are left to consider \( N > 1 \). Let \( j \) be any integer \( 0 < j < N - 1 \). Then

\[
(13) \quad \int_{-1}^{1} b(y) \phi_j(y) \phi_{N+1}(y) \, dy = \int_{-1}^{1} \frac{d}{dy} a \left( \sum_{i=0}^{j+2} a^i \phi_i(y) \right) \phi_{N+1}(y) \, dy,
\]

where the \( \alpha_i \)'s are selected such that \( P(\sum_{i=0}^{j+2} \alpha_i \phi_i) = \phi_j \).

This is possible because \( \{\phi_j\}_{j=0}^{\infty} \) is an optimal sequence of basis functions. Since \( N > 1 \) and \( f_{-1}^{+1} ds/a(s) \in \mathcal{L}_s(P) \), we also have that

\[
\phi_{N+1}(1) - \phi_{N+1}(-1) = \int_{-1}^{1} a \left( \int_{-1}^{y} \frac{1}{a(s)} \, ds \right) \frac{d}{dy} \phi_{N+1} \, dy = 0.
\]

We already know that \( \phi_{N+1}(-1) = 0 \), i.e., we conclude

\[
(14) \quad \phi_{N+1}(1) = \phi_{N+1}(-1) = 0.
\]

It follows immediately from an integration by parts in (13) and application of (14) that for any integer \( 0 < j < N - 1 \)

\[
\int_{-1}^{1} b(y) \phi_j(y) \phi_{N+1}(y) \, dy = \sum_{i=0}^{j+2} \alpha_i \int_{-1}^{1} a(y) \frac{d}{dy} \phi_i \frac{d}{dy} \phi_{N+1} \, dy = 0.
\]

The last identity is due to the orthogonality of \( \{\phi_j\}_{j=0}^{\infty} \) and the fact that \( i < N + 1 \).

In summary we have therefore proven

\[
\langle M_{e_{N+1}} \cdot x \rangle \int_{-1}^{1} a \left( \frac{d}{dy} \phi_{N+1} \right)^2 \, dy = -h \int_{-h}^{h} b_h \langle A u_N^h, \phi_{N+1}(y/h) x \rangle \, dy
\]

\[
\quad \text{(here again we used (14))}
\]

\[
= -h^2 \left( \langle A x_{N-1} \cdot x \rangle \int_{-1}^{1} b \phi_{N-1} \phi_{N+1} \, dy + \langle A x_N \cdot x \rangle \int_{-1}^{1} b \phi_N \phi_{N+1} \, dy \right),
\]

that is,

\[
(15) \quad e_{N+1} = h^2 M^{-1} A (c_N x_{N-1} + \bar{c}_N x_N),
\]

with the explicit expressions for \( c_N \) and \( \bar{c}_N \) as given above.

Along exactly the same lines we also get

\[
e_{N+2} = h^2 M^{-1} A c_{N+1} x_N,
\]

and therefore the desired result for the function \( d e / dy \). □

Lemma 3.1 immediately leads to

**Theorem 3.3.** Let \( \{\phi_j\}_{j=0}^{\infty} \) be a sequence with properties as in the previous lemma. Let \( u_N^h = \sum_{j=0}^{N} \phi_j(y/h)x_j \) denote the corresponding dimensionally reduced solution of order \( N \). If \( Est \) is as defined in (8), then there exist constants \( \{C_k\}_{k=0}^{\infty} \) and \( \{\bar{C}_k\}_{k=0}^{\infty} \) such that

\[
Est = h^{3/2} \left( \| M^{-1/2} (C_0 (f + g) + C_0 (f - g)) \|_2^2 + h^{-2} + \| M^{-1/2} A C_1 x_0 \|_2^2 \right)^{1/2}
\]

for \( N = 0 \)

and

\[
Est = h^{3/2} \left( \| M^{-1/2} A (C_N x_{N-1} + \bar{C}_N x_N) \|_2^2 + \| M^{-1/2} A C_{N+1} x_N \|_2^2 \right)^{1/2}
\]

for \( N > 1 \).
From the formulae contained in the proof of Lemma 3.1 it follows that the constants \( \{c_k, \tilde{c}_k\}_{k=0}^{\infty} \) and \( \{C_k, \tilde{C}_k\}_{k=0}^{\infty} \), respectively, are readily computable based on the sequence \( \{\phi_j\}_{j=0}^{\infty} \). The following example gives the exact values in the case of constant coefficients \( a \) and \( b \).

**Example 3.1.** If the functions \( a \) and \( b \) are both constant, it immediately follows that every optimal sequence of basis functions \( \{\phi_j\}_{j=0}^{\infty} \) satisfies

\[
\text{span}\{\phi_j\}_{j=0}^{N} = \text{all polynomials of degree } \leq N
\]

for any \( N > 0 \), and vice versa.

The specific optimal sequence of basis functions \( \{\phi_j\}_{j=0}^{\infty} \) used in Lemma 3.1 and Theorem 3.3 is now (modulo a scalar)

\[
\phi_0 = 1, \quad \phi_1(y) = y, \\
\phi_j(y) = \int_{-1}^{1} l_{j-1}(t) \, dt, \quad j > 2,
\]

where \( l_k \) denotes the Legendre polynomial of degree \( k \) (normalized so that \( \int_{-1}^{1} l_k^2(t) \, dt = 2(2k + 1) \)).

Because of the alternating even and odd polynomials, it immediately follows that

\[
\tilde{c}_k = \tilde{C}_k = 0 \quad \forall \ k > 0.
\]

Simple algebraic manipulations with the Legendre polynomials now give

\[
c_0 = 1/2a, \quad c_1 = b/a
\]

and

\[
c_k = b/((2k - 1)(2k - 3)a) \quad \text{for } k > 2.
\]

From the definition of \( C_k \) it immediately follows that

\[
C_k = \left( \int_{-1}^{1} a \left( \frac{d}{dy} \phi_{k+1} \right)^2 \, dy \right)^{1/2} \cdot c_k,
\]

i.e.,

\[
C_0 = [1/2a]^{1/2}, \quad C_1 = [2b^2/3a]^{1/2},
\]

and

\[
C_k = [2b^2/((2k + 1)(2k - 1)^2(2k - 3)^2a)]^{1/2} \quad \text{for } k > 2.
\]

We shall now show how one can derive another set of formulae for the a posteriori error estimator. As it will turn out these formulae are much better suited for practical applications. For the case \( N = 0 \) it is clear that \( Ax_0 = C h^{-1}(f - g) \).

In the following we therefore only consider \( N > 1 \).

**Lemma 3.2.** Let \( \{ C_k \}_{k=0}^{\infty} \), \( \{\tilde{C}_k\}_{k=0}^{\infty} \) and \( u_h^N = \Sigma_{j=0}^{N} \phi_j(y/h)x_j \) be as in the previous theorem. Then there exist constants \( D_{ij}^N \), \( 1 < i, j < 2 \), such that

\[
A(C_N x_{N-1} + \tilde{C}_N x_N) = h^{-1}D_{11}^N M\left( g - a_h \frac{d}{dy} Mu_N^h(h) \right) + h^{-1}D_{12}^N M\left( f - a_h \frac{d}{dy} Mu_N^h(-h) \right)
\]
and

\[ AC_{N+1}x_N = h^{-1}D^2_N\left( g - a_h \frac{d}{dy} Mu_N^h(h) \right) \]

\[ + h^{-1}D^2_N\left( f - a_h \frac{d}{dy} Mu_N^h(-h) \right) \quad \text{for } N > 1. \]

**Proof.** From (5) and Lemma 3.1 it follows that

\[ -P_h\left( \frac{d}{dy} \right) Mu_N^h - b_h Au_N^h = -\left( \frac{d}{dy} a \frac{d}{dy} \phi_{N+1} \right) \left( y/h \right) A(c_Nx_{N-1} + \tilde{c}_N x_N) \]

\[ - \left( \frac{d}{dy} a \frac{d}{dy} \phi_{N+2} \right) \left( y/h \right) Ac_{N+1}x_N. \]

If we integrate the right-hand side of (6) by parts, set \( v = \phi_0(y/h) \cdot x \), and apply the identity (16), the result is

\[ hd^1_{N}A(c_Nx_{N-1} + \tilde{c}_N x_N) + hd^2_{N}Ac_{N+1}x_N = g - a_h \frac{d}{dy} Mu_N^h(-h) \]

with

\[ d^1_{N} = \int_{-1}^{1} \frac{d}{dy} a \frac{d}{dy} \phi_{N+1} \, dy \quad \text{and} \quad d^2_{N} = \int_{-1}^{1} \frac{d}{dy} a \frac{d}{dy} \phi_{N+2} \, dy. \]

Performing the similar procedure with \( v = \phi_1(y/h) \cdot x \), instead we get

\[ hd^1_{N}A(c_Nx_{N-1} + \tilde{c}_N x_N) + hd^2_{N}Ac_{N+1}x_N \]

\[ = \phi_1(1) \left( g - a_h \frac{d}{dy} Mu_N^h(h) \right) - \phi_1(-1) \left( f - a_h \frac{d}{dy} Mu_N^h(-h) \right) \]

with

\[ d^1_{N} = \int_{-1}^{1} \frac{d}{dy} a \frac{d}{dy} \phi_{N+1} \phi_1 \, dy \quad \text{and} \quad d^2_{N} = \int \frac{d}{dy} a \frac{d}{dy} \phi_{N+2} \phi_1 \, dy. \]

The lemma therefore immediately follows if the matrix

\[ d_N = \{ d^j_N \}_{i,j=1} \]

is always invertible. The proof of the invertibility follows by contradiction. Assume \( d_N \) is not invertible for some \( N \). This implies that some nontrivial linear combination of the columns of \( d_N \) vanishes. In terms of the functions \( \phi_{N+1} \) and \( \phi_{N+2} \) this says that some nontrivial linear combination \( s_1\phi_{N+1} + s_2\phi_{N+2} \) exists such that

\[ \int_{-1}^{1} \frac{d}{dy} a \frac{d}{dy} (s_1\phi_{N+1} + s_2\phi_{N+2}) \, dy = 0 \]

for \( \nu = \phi_0 \) and \( \nu = \phi_1 \). By performing an integration by parts we easily see that this identity must also hold for \( \nu = \phi_j, \ 2 < j < N \). Since the sequence \( \{ \phi_j \}_{j=0}^{N} \) is an optimal sequence of basis functions, we know that

\[ \frac{d}{dy} a \frac{d}{dy} (s_1\phi_{N+1} + s_2\phi_{N+2}) = b \sum_{j=0}^{N} \alpha_j \phi_j \]

for some set of constants \( \{ \alpha_j \}_{j=0}^{N} \). Combining this with (17) we conclude that

\[ \frac{d}{dy} a \frac{d}{dy} (s_1\phi_{N+1} + s_2\phi_{N+2}) = 0. \]
Due to the fact that $s_1\phi_{N+1}(y) + s_2\phi_{N+2}(y) = 0$ for $y = \pm 1$, this implies

$$s_1\phi_{N+1} + s_2\phi_{N+2} = 0,$$

which obviously contradicts the fact that this is a nontrivial linear combination.

The difference between the formulae given in Theorem 3.3 and those that are based on Lemma 3.2 is that while the first include elements of the form $Ax_j$ the latter are expressed solely in terms of $f$, $g$ and the $x_j$'s. In practical applications we seldom know the exact values of the $x_j$'s. Instead we compute some approximate values $\tilde{x}_j$, e.g. using a finite element method. The error introduced by using approximate values, derived from finite elements, in the expressions of Lemma 3.2 can be neglected. The reason is that the difference between $x_j$ and $\tilde{x}_j$ in the $\mathcal{C}$ norm (viz. $L^2$) is normally very small. The problem with the expressions of Theorem 3.3 in this context is that in general $Ax_j$ is not at all defined.

As before we now give the values of the constants $D_N^i$ in the case where $a$ and $b$ are both constants.

**Example 3.2.** Assume $a$ and $b$ are constants. In this case we already know that $C_N = 0$. Lemma 3.2 therefore reduces to formulae for $AC_{N}x_{N-1}$ and $AC_{N+1}x_{N}$, $N > 1$. It is easily seen that these are

$$AC_{N}x_{N-1} = h^{-1}(2a(2N + 1))^{1/2}\left[\left(g - a_h \frac{d}{dy}Mu_N^h(h)\right) + (-1)^N\left(f - a_h \frac{d}{dy}Mu_N^h(-h)\right)\right]$$

$$AC_{N+1}x_{N} = h^{-1}(2a(2N + 3))^{1/2}\left[\left(g - a_h \frac{d}{dy}Mu_N^h(h)\right) + (-1)^{N+1}\left(f - a_h \frac{d}{dy}Mu_N^h(-h)\right)\right]$$

for $N > 1$.

**4. Improved Error Estimation—A Specific Example.** As mentioned before it is very important that we are able to estimate the error accurately. Theorem 3.2 shows that our estimator Est does exactly that provided the data is sufficiently regular and $h$ is not too large. In this section we shall address the problem of how to detect if the estimator Est is too conservative, due to singularities in the data or large $h$, and what can be done to correct it. For simplicity we consider the model problem

$$\left[\left(\frac{\partial}{\partial x}\right)^2 + \left(\frac{\partial}{\partial y}\right)^2\right]u^h = 0 \quad \text{in } \Omega^h = [0, 1] \times [-h, h],$$

$$\frac{\partial u^h}{\partial y} = g \quad \text{for } y = h,$$

$$\frac{\partial u^h}{\partial y} = -g \quad \text{for } y = -h,$$

$$u^h = 0 \quad \text{for } x = 0, 1,$$

where $g$ is an element of $L^2([0, 1])$. 

ON A DIMENSIONAL REDUCTION METHOD. III

Let \( \{ \phi_j \}_{j=0}^{\infty} \) be the sequence of polynomials introduced in Example 3.1. The dimensionally reduced solution of order \( N \), \( u_N^h \), has the form

\[
u_N^h(x, y) = \sum_{j=0}^{N} \phi_j(y/h)v_j(x),\]

where \( v_j \in H^1([0, 1]) \), \( 0 < j < N \). Let \( e_N \) denote the exact error, i.e., \( e_N = u^h - u_N^h \).

Since everything is even in \( y \), all the terms in the dimensionally reduced solutions corresponding to odd indices vanish. From here on we only consider dimensionally reduced solutions of even order \( 2N \). Let us start by giving a table that shows the relative error \( (= \| e_{2N} \|_{L^2}/\| u^h \|_{L^2}) \) and the efficiency index of the estimator \( \text{Est} \) \( (\text{Eff} = \| e_{2N} \|_{L^2}/\text{Est}) \) in the case \( g(x) = \pi/4 \), for \( N = 0 \) and \( N = 1 \), respectively, and for different values of \( h \).

### Table 4.1

<table>
<thead>
<tr>
<th>( h )</th>
<th>( N = 0: ) Rel.Error</th>
<th>Eff.</th>
<th>( h )</th>
<th>( N = 1: ) Rel.Error</th>
<th>Eff.</th>
</tr>
</thead>
<tbody>
<tr>
<td>1/2</td>
<td>0.67</td>
<td>0.88</td>
<td>1/2</td>
<td>0.12</td>
<td>0.69</td>

<td>0.68</td>
</tr>
</tbody>
</table>

From the table it is evident that the efficiency index approaches 1, as \( h \to 0 \), for \( N = 0 \), but that this is not so for \( N = 1 \). The numbers therefore clearly show that some smoothness condition, as in Theorem 3.2, is essential in order to ensure that this index converges to 1 for \( h \to 0 \). For most practical applications though, an efficiency index of 0.7 is completely satisfactory and no corrections to \( \text{Est} \) are needed. It is also important to note that \( h = 1/2 \) corresponds to a square and that \( \text{Est} \) still gives a very reliable estimate for the error. The next table lists the efficiency index, also in the case where \( g(x) = \pi/4 \), but for \( N = 2 \) and \( N = 3 \), and three different values of \( h \).

### Table 4.2

In the following we shall take a closer look at the derivation of the estimator \( \text{Est} \) for the purpose of suggesting corrections that can increase the efficiency to any desired level. We shall only work out the details of a first correction.

License or copyright restrictions may apply to redistribution; see https://www.ams.org/journal-terms-of-use
The exact error $e_{2N}$ is the solution to the boundary value problem

$$
\left[ \left( \frac{\partial}{\partial x} \right)^2 + \left( \frac{\partial}{\partial y} \right)^2 \right] e_{2N} = r_{2N} \quad \text{in } \Omega^h,
$$

$$\frac{\partial e_{2N}}{\partial y} = \rho_{2N} \quad \text{for } y = h,
$$

$$\frac{\partial e_{2N}}{\partial y} = -\rho_{2N} \quad \text{for } y = -h,
$$

$$e_{2N} = 0 \quad \text{for } x = 0, 1,$n

with

$$r_{2N} = -\left[ \left( \frac{\partial}{\partial x} \right)^2 + \left( \frac{\partial}{\partial y} \right)^2 \right] u_{2N}^h(x, y)$$

and

$$\rho_{2N} = g(x) - \frac{\partial}{\partial y} u_{2N}^h(x, h).$$

In terms of complementary energy the norm of $e_{2N}$, $||e_{2N}||_E$, can now be characterized by

$$||e_{2N}||^2_E = \min_{(s, t) \in \mathcal{R}} \int_0^1 \int_{-h}^h (s(x, y) + t^2(x, y)) \, dy \, dx,$$

where

$$(s, t) \in \mathcal{R} \quad \text{if and only if } (s, t) \in (L^2(\Omega^h))^2,$$

$$\frac{\partial}{\partial x} s + \frac{\partial}{\partial y} t = r_{2N},$$

$$t = \rho_{2N} \quad \text{for } y = h \quad \text{and} \quad t = -\rho_{2N} \quad \text{for } y = -h.$$

If we define $t_0$ by

$$\frac{\partial}{\partial y} t_0 = r_{2N}, \quad t_0 = \rho_{2N} \quad \text{for } y = h$$

then

$$t_0 = -\rho_{2N} \quad \text{for } y = -h,$$

and it is clear that $(0, t_0) \in \mathcal{R}$. On the other hand, it is also clear that $\text{Est} = (\int_0^1 \int_{-h}^h t_0^2(x, y) \, dy \, dx)^{1/2}$, i.e., $\text{Est}$ is simply a particular value of a functional, the minimal value of which is the exact norm of the error. One way to improve the estimator $\text{Est}$ is therefore to take the minimum over more than just the single function $t_0$. This should not be exaggerated since we also have to keep the formulae simple. Define

$$s(x, y) = \int_0^x \left( r_{2N}(z, y) - \tilde{r}_{2N}(z) \left( \frac{d}{dy} \xi \right)(y/h) \right) \, dz$$

and

$$t(x, y) = h\tilde{r}_{2N}(x)\xi(y/h),$$

where $\tilde{r}_{2N}(x)$ denotes the function

$$\tilde{r}_{2N}(x) = \frac{1}{2h} \int_{-h}^h r_{2N}(x, y) \, dy,$$
and \( \zeta \) is an arbitrary element of \( H^1([0,1]) \). It is obvious that
\[
\frac{\partial}{\partial x} s + \frac{\partial}{\partial y} t = r_{2N}.
\]
If furthermore \( \zeta \) satisfies \( \zeta(1) = 1, \zeta(-1) = -1 \), it also follows that
\[
t = \rho_{2N} \quad \text{for } y = h \quad \text{and} \quad t = -\rho_{2N} \quad \text{for } y = -h.
\]
From Lemma 3.1 we get the identity
\[
r_{2N}(x,y) = \left( \frac{d}{dy} l_{2N+1} \right) (y/h) \cdot \tilde{r}_{2N}(x),
\]
where \( l_{2N+1} \) as before denotes the Legendre polynomial of degree \( 2N + 1 \), so it immediately follows that
\[
\left( \int_0^1 \int_{-h}^h (s^2(x,y) + t^2(x,y)) \, dy \, dx \right) = \left( h^3 \int_{-1}^1 \zeta^2(y) \, dy \int_0^1 (\tilde{r}_{2N}(x))^2 \, dx \right) + h \int_{-1}^1 \left( \frac{d}{dy} (l_{2N+1}(y) - \zeta(y)) \right) \, dy \int_0^1 (\int_0^x \tilde{r}_{2N} \, dx)^2 \, dx \right)^{1/2}.
\]
It should be noticed that the estimator \( \text{Est} \) is obtained from this with the choice \( \zeta(y) = l_{2N+1}(y) \). If we define
\[
A(h) = \int_0^1 (\tilde{r}_{2N}(x))^2 \, dx
\]
and
\[
B(h) = \int_0^1 \left( \int_0^x \tilde{r}_{2N} \, dx \right)^2 \, dx,
\]
then the previous expression can be written as
\[
\left( \int_{-1}^1 \zeta^2(y) \, dy A(h) + \int_{-1}^1 \left( \frac{d}{dy} (l_{2N+1}(y) - \zeta(y)) \right) \, dy B(h) \right)^{1/2}.
\]
It is easy to see that the minimum of this expression over \( \zeta \) approaches
\[
\left( \int_{-1}^1 l_{2N+1}^2(y) \, dy A(h) \right)^{1/2} = \text{Est}
\]
as \( A(h)/B(h) \to 0 \). In the case that \( A(h)/B(h) \to \infty \), the minimum of the expression (18) approaches
\[
(4A(h)B(h))^{1/4}.
\]
Based on these asymptotics we introduce a new estimator \( \text{Est}_1 \) by
\[
\text{Est}_1 = \begin{cases} 
\text{Est} & \text{if } A(h)/B(h) < \tau, \\
\left(4A(h)B(h)\right)^{1/4} & \text{if } A(h)/B(h) > \tau,
\end{cases}
\]
where \( \tau \) is some specified constant. The quantity \( A(h)/B(h) \) will therefore tell us whether we shall use the value of the old estimator \( \text{Est} \) or not. Since we know that \( h\tilde{r}_{2N}(x) = \rho_{2N}(x) \), \( A(h) \) and \( B(h) \) can very easily be expressed in terms of \( \rho_{2N} \). It follows from this that \( A(h)/B(h) \) is small exactly if \( h \) is small and \( \rho_{2N} \) is sufficiently
smooth. Since the smoothness of $\rho_{2N}$ may sharply vary on the interval $[0, 1]$, we get that the estimator $\text{Est}$ may well give a good estimation of the error in parts of $[0, 1]$ but not in others. We therefore divide the interval $[0, 1]$ into $K$ disjoint subintervals $I_j$, $1 \leq j \leq K$, and define

$$\text{Est}_2 = \left( \sum_{j=1}^{K} \text{Est}_1(I_j)^2 \right)^{1/2},$$

where $\text{Est}_1(I_j)$ refers to the estimator $\text{Est}_1$ computed on the interval $I_j$. The following table shows the efficiency index of the estimator $\text{Est}_2$ ($\text{Eff}_2 = \|\varepsilon_{2N}\|_E / \|\text{Est}_2\|$) in the case $g(x) = \pi/4$ for $N = 2, 3$ and three different values of $h$. The interval $[0, 1]$ was divided into eight subintervals of equal length, i.e. $K = 8$, and the constant $r$ in the definition of $\text{Est}_1$ was chosen to be $10^2$.

Although the efficiency index is not quite 1, Table 4.3 shows a definite improvement over Table 4.2. Again note that the efficiency is almost independent of $h$. If additional accuracy of the estimator is deemed necessary, this can obviously be obtained by an extension of the technique used to derive $\text{Est}_2$. Whether such additional corrections are worthwhile in the end of course depends on the balance between the cost of computing the estimator and what is computationally to be gained from a more accurate estimator.

5. Some Remarks on an Adaptive Strategy. As already mentioned in the introduction, the goal of this paper is not only to derive reliable estimates for the error, but also to use these estimates as tools in an automatic selection of the right order dimensionally reduced solution for a given problem.

First let us introduce a slight generalization of the concept of dimensionally reduced solution. Instead of projecting onto the space $\{\Sigma_{j=0}^{N} \psi(y/h)x_j | x_j \in \mathcal{D}(A^{1/2}) \}$, $j = 0, \ldots, N$, we project onto $\{\Sigma_{j=0}^{N} \psi(y/h)x_j | x_j \in \mathcal{Y}_j \}$, $j = 0, \ldots, N$, where $\{\mathcal{Y}_j\}^N_{j=0}$ is a family of closed subspaces of $\mathcal{D}(A^{1/2})$.

To see the importance of this generalization and describe the ideas behind the self-adaptive strategy, we shall consider the case that $A$ is a differential operator on some domain $\Omega$. Let $\Omega$ be divided into $k$ disjoint subdomains $\Omega_i$, $1 \leq i \leq k$, and let $N_i$, $1 \leq i \leq k$, be $k$ nonnegative integers. Set $\mathcal{Y}_j = \{ u \in \mathcal{D}(A^{1/2}) | u(x) = 0 \text{ for } x \in \cup_{N_i \leq j} \Omega_i \}$, the extended concept of dimensionally reduced solutions with this family $\{\mathcal{Y}_j\}^N_{j=0}$, $N = \max_i \{N_i\}$, is one that permits different order of the dimensionally reduced solution in different parts of the domain $\Omega$. This is extremely important for practical applications, where a low order dimensionally reduced solution may very well be satisfactory in the interior of the domain and away from singularities in the loads and at the same time a high order solution is required near
the boundary or near singularities. As a total estimator for the error, let us use an expression of the form

$$\left( \sum_{i=1}^{k} \left[ \eta_i(N_i) \right]^2 \right)^{1/2},$$

where $\eta_i(N_i)$ refers to some estimator on the domain $\Omega_i$ with respect to dimensional reduction of order $N_i$. ($\eta_i$ could for example be the estimator $\text{Est}$ or the corrected estimator $\text{Est}_2$ of the previous section.)

To set a goal for the 'best' distribution of the orders $\{N_i\}_{i=1}^{k}$ for a dimensionally reduced solution we need the concept of cost. Let us assume that the cost of (solving) the dimensionally reduced problem with orders $\{N_i\}_{i=1}^{k}$ is given by $\Sigma_{i=1}^{k} (\beta N_i + 1)^{\alpha} m(\Omega_i)$, where $\alpha$ and $\beta$ are two positive constants and $m(\Omega_i)$ is some measure of $\Omega_i$.

As a 'best' distribution of the orders for a dimensionally reduced solution we define one which for a given cost minimizes the energy norm of the error. (We could also have defined a 'best' distribution as one that for a given value of the energy norm of the error minimizes the cost. Which of these two definitions we take makes no difference in the strategy we propose.)

The following is very heuristic in nature and by no means an exact verification that the strategy works. Let us use the expression (19) as if it were the exact norm of the error. Secondly, let us assume this expression to be defined for all positive values of the $N_i$'s, and not only integers. By introduction of Lagrangean multipliers it is easily seen that a 'best' distribution of the $N_i$'s has to satisfy

$$\exists C \text{ (independent of } i \text{) such that } \frac{(\partial / \partial N_i)\left[ \eta_i(N_i) \right]^2}{(\beta N_i + 1)^{\alpha - 1} m(\Omega_i)} \sim C, \text{ } \forall i.$$  

In practice we only have the values of the $\eta_i$'s at integer points and a discrete equivalent of (20) is then

$$\frac{[\eta_i(N_i + 1)]^2 - [\eta_i(N_i)]^2}{(\beta N_i + 1)^{\alpha - 1} m(\Omega_i)} \sim C, \text{ } \forall i.$$  

We shall also assume that $\eta_i(N_i + 1)$ is significantly smaller than $\eta_i(N_i)$, so that instead of (21) we get

$$\frac{[\eta_i(N_i)]^2}{(\beta N_i + 1)^{\alpha - 1} m(\Omega_i)} \sim C, \text{ } \forall i.$$  

The strategy we propose is one that aims at equilibrating the left-hand sides of (22). We do this in a way similar to the adaptive finite element solver F.E.A.R.S.; cf. [1]. Let us assume that we have arrived at a distribution $\{N_i^0\}_{i=1}^{k}$ and that the estimate for the error is unacceptably large. Our strategy is simply to find $j$ such that

$$\delta_j = \frac{[\eta_j(N_j^0)]^2}{(\beta N_j^0 + 1)^{\alpha - 1} m(\Omega_j)}$$

is maximal, and then increase $N_j^0$ by 1. In the next section we shall see how well this performs in a practical example.
6. A Numerical Example. Consider the same problem as in Section 4, namely

\[
\left( \frac{\partial}{\partial x} \right)^2 + \left( \frac{\partial}{\partial y} \right)^2 u^h = 0 \quad \text{in} \quad \Omega^h = [0, 1[ \times ]-h, h[,
\]

\[
\frac{\partial u^h}{\partial y} = g \quad \text{for} \quad y = h,
\]

\[
\frac{\partial u^h}{\partial y} = -g \quad \text{for} \quad y = -h,
\]

\[
u^h = 0 \quad \text{for} \quad x = 0, 1.
\]

Let \([0, 1]\) be divided into the four subintervals \(I_i = [(i - 1)/4, i/4], 1 < i < 4\). A dimensionally reduced solution can now have different order in the different intervals \(I_i, 1 < i < 4\). As basis functions we choose the polynomials introduced in Example 3.1.

</table>
The equations that define the dimensionally reduced solutions are solved by introducing a finite element discretization in the \( x \)-direction. Piecewise linear functions on a regular mesh are used as test and trial functions for the finite element method. Since we want to illustrate the behavior of the dimensional reduction, and are here not interested in any contribution from the \( x \)-discretization, we choose a very fine grid of meshsize \( = 2^{-9} \). The involved linear equations are solved by a Cholesky decomposition combined with iterative refinement. In the computations that we present here \( g(x) \) is chosen \( = \pi/4 \). Since this choice of boundary data makes the problem symmetric in the line \( x = \frac{1}{2} \) we only need consider \( x \) in the interval \([0, \frac{1}{2}]\). Let \( 2N_i, 1 < i < 2 \), denote the order of the dimensionally reduced solution in \( I_i \). The above table shows the error on the whole interval \([0, 1]\) \( (= \| e_\tilde{N} \|_E) \) and the work (here defined by \( \frac{1}{2}(N_1 + 1)^3 + \frac{1}{2}(N_2 + 1)^3 \)) as a function of the pair \( \tilde{N} = 2\tilde{N} = (2N_1, 2N_2) \) for two different values of \( h \).

Based on the numbers in this table we can now find the entries with the property that the error is smaller than any error obtained with the same or less work. These entries are marked in the following table.
Tables 6.1 and 6.2 clearly illustrate the advantage of a nonuniform distribution of the polynomials. It is easy to see that the true solution $\mu^h$ in the limit as $h \to 0$ has a parabolic behavior in the $y$ direction, also for $x$ in the middle of the interval $[0, 1]$. This is reflected in the fact that the pair $(0, 2)$ is slightly better than $(2, 0)$, it also explains the significant decrease in the error obtained by choosing the pair $(2, 2)$. For the higher order polynomials there is a clear tendency towards concentration near the boundary $x = 0$ (and $x = 1$) in the entries marked in Table 6.2. This concentration is more visible the smaller $h$ is; for $h = \frac{1}{2}$ the pair $(6, 2)$ is not as good as $(4, 4)$ but for $h = \frac{1}{4}$ the error obtained by $(6, 2)$ is less than half the error by $(4, 4)$ with only a slight increase in the work.

We now want to test the adaptive strategy outlined in Section 5 on this example. We consider the case $h = \frac{1}{4}$, where nonuniformity in the distribution of the polynomials is most advantageous. As an estimator we use $\text{Est}_2$ of Section 4, with the constant $\tau$ set to $10^2$ and each interval $I$ divided into 2 subintervals of length $\frac{1}{8}$. The following table shows the efficiency of $\text{Est}_2$ ($\text{Eff}_2 = \frac{\|e_2\|}{\text{Est}_2}$) as a function of the pair $2\mathbf{N} = (2N_1, 2N_2)$. It is evident from Table 6.3 that $\text{Est}_2$ provides a reliable estimate for the error even in the case of variable order. We also note that $\text{Est}_2$ is not necessarily an upper bound for the error, when the orders of the polynomials are allowed to vary. Steps could be taken to correct this, but on the other hand computational experience shows that this effect is insignificant, and that $\text{Est}_2$ is very close to an upper bound in most cases.

</table>

Let us start with an initial distribution for the orders of the polynomials given by $(2N_1, 2N_2) = (0, 0)$.

Based on the present formula for the work and the error estimate, we now compute $\delta_j, j = 1, 2$, as in Section 5. The result is

$\delta_1 = \delta_2 = 0.10$.

We can therefore proceed to both $(0, 2)$ and $(2, 0)$. According to Table 6.1, $(0, 2)$ is only slightly better than $(2, 0)$, so this apparent "failure" of our strategy is of very little significance.
For the pair (0, 2) we compute
\[ \delta_1 = 0.10, \quad \delta_2 = 0.14 \times 10^{-2} \]
and for the pair (2, 0)
\[ \delta_1 = 0.31 \times 10^{-2}, \quad \delta_2 = 0.10. \]
In both of these two cases we are told to proceed to the distribution given by
(2, 2).

For this pair we get
\[ \delta_1 = 0.14 \times 10^{-2} \quad \text{and} \quad \delta_2 = 0.59 \times 10^{-6}, \]
i.e., if we want higher accuracy with dimensional reduction, our strategy selects the pair
(4, 2).

In this case
\[ \delta_1 = 0.14 \times 10^{-3} \quad \text{and} \quad \delta_2 = 0.16 \times 10^{-5}, \]
so that additional requirements to the accuracy will lead us to the distribution
(6, 2).

The path that our strategy goes through can schematically be represented as

\[
\begin{array}{c}
(0, 2) \\
\uparrow \\
(0, 0) & \downarrow & (2, 2) & \rightarrow & (4, 2) & \rightarrow & (6, 2) \\
\downarrow & \uparrow \\
(2, 0)
\end{array}
\]

and based on Tables 6.1 and 6.2 this is clearly seen to be a very good choice. The strategy has been tried in a variety of other situations and has consistently been very effective. It has also been tried with different measures for the work. Here it should be noted that by changing the measure of the work we may entirely change the “best” distributions for the polynomials, but the strategy detects that easily.

7. Conclusions. In the following we list some conclusions concerning the approach of dimensional reduction developed in a series of three papers ([6], [7], and the present).

(a) It is common in engineering to distinguish between structures with large and small thickness (see, e.g., [3]). The approach presented here entirely avoids this somewhat artificial categorization.

(b) This approach gives, in an optimal and adaptive way, the advantages of asymptotic expansion (when the thickness is small) and the effectivity of the spectral or \( p \)-version methods (when the thickness is not small, or strong singularities are present). It has been shown that these two requirements uniquely characterize the approach.

(c) Reliable a posteriori error estimates can be obtained for this approach, and they lead immediately to an effective adaptive strategy.

(d) The approach is numerically very robust and works well independent of the thickness and the regularity of input data.
The underlying mathematical theory and numerical experiments show the
direction for various generalizations. These shall be dealt with elsewhere.
