A Uniformly Accurate Finite-Element Method for a Singularly Perturbed One-Dimensional Reaction-Diffusion Problem

By Eugene O'Riordan and Martin Stynes

Abstract. A finite-element method with exponential basis elements is applied to a selfadjoint, singularly perturbed, two-point boundary value problem. The tridiagonal difference scheme generated is shown to be uniformly second-order accurate for this problem (i.e., the nodal errors are bounded by $Ch^2$, where $C$ is independent of the mesh size $h$ and the perturbation parameter). With a certain choice of trial functions, uniform first-order accuracy is obtained in $L^2[0,1]$.

1. Introduction. We consider the following two-point boundary value problem:

$$Ly = \varepsilon^2 (py')' - r y = f \quad \text{on} \ (0,1),$$
$$y(0) = y_0, \quad y(1) = y_1,$$

where $\varepsilon$ is a parameter in $(0,1]$, $y_0$ and $y_1$ are given constants, the coefficients $p$, $r$, and $f$ are in $C^2[0,1]$ and satisfy

$$p(x) \geq \xi > 0 \quad \text{and} \quad r(x) \geq \beta > 0 \quad \text{for} \ x \in [0,1].$$

The solution $y(x)$ has, in general, a boundary layer of width $O(\varepsilon)$ at both end points of $[0,1]$.

Letting $y(x) = w(x) (p(x))^{-1/2}$, this problem transforms into

$$\varepsilon^2 w'' - d(x) w = g(x),$$
$$w(0) = y_0 (p(0))^{1/2}, \quad w(1) = y_1 (p(1))^{1/2},$$

where $d(x)$ and $g(x)$ are easily computed.

However, since $d(x)$ involves both first and second derivatives of $p(x)$, a discretization of this transformed problem is not attractive from a numerical point of view. In this paper, we present a numerical method which is directly applicable to problem (1.1).

Finite-difference schemes for singularly perturbed selfadjoint problems of the form (1.2), which are uniformly in $\varepsilon$ accurate, have been examined by various authors. Miller [6] gave sufficient conditions for the uniform first-order convergence of a general three-point difference scheme. Hegarty et al. [4] and Nijjima [7] produced uniformly second-order difference schemes. Boglaev [1] examined problem...
(1.2) in a finite-element framework and achieved uniform first-order accuracy at the nodes. Shishkin [11] examined problem (1.1) on a nonuniform mesh, which depends on $\varepsilon$, and obtained convergence results for various difference schemes. A useful discussion of uniform convergence of difference schemes for singularly perturbed two-point boundary value problems is obtained in Doolan, Miller, and Schilders [2]. Schatz and Wahlbin [10] examined problem (1.2) in both one and two dimensions, using a Galerkin finite-element method.

A weak form of problem (1.1) is:

\[(1.3) \quad B_\varepsilon(y, v) = -\varepsilon^2(p y', v') - (r y, v) = (f, v) \quad \text{for all } v \in H_0^1(0,1),\]
\[y(0) = y_0, \quad y(1) = y_1,\]

where $(, \,)$ denotes the usual inner product in $L^2$.

In this paper, we will discretize (1.3) using a Petrov-Galerkin finite-element method with exponential test functions and a quadrature rule that replaces the functions $p$, $r$, and $f$ by piecewise-constant approximations. This enables exact evaluation of the modified integrals in (1.3). By introducing a discretized Green’s function, the nodal errors are given explicitly in integral form. Our approximation will be shown to be uniformly second-order accurate at the nodes. The crux of the proof lies in suitably bounding the discretized Green’s function and its derivative. Using exponential trial functions to interpolate between these nodal values, our approximation is then shown to be uniformly first-order accurate in $L^\infty[0,1]$. Thus the second-order nodal accuracy is a superconvergence result.

For a discussion of exponential elements, see Hemker [5], de Groen [3] and the references therein. A discretized Green’s function was first used by Stynes and O’Riordan [12] to prove a superconvergence result for a nonselfadjoint singularly perturbed two-point boundary value problem.

**Note.** Throughout this paper, $C$ will be used to denote a generic constant independent of $x$, $j$, $h$, and $\varepsilon$. Also, $g = O(h^p)$ means $|g| \leq Ch^p$, $p = 0, 1, 2$.

2. The Continuous Problem. The differential operator $L$ in (1.1) satisfies a maximum principle (see Protter and Weinberger [8]). We state this formally as

**Lemma 2.1.** If $w(0) \leq 0$, $w(1) \leq 0$, $w \in C^2[0,1]$ and $Lw \geq 0$, then $w \leq 0$ on $[0,1]$.

In order to obtain the appropriate bounds on the derivatives of the solution of (1.1), we will require some information about the solutions of

\[(2.1) \quad Lw = g(x, \varepsilon), \quad |w(0)| \leq C \quad \text{and} \quad |w(1)| \leq C.\]

We will say that $g$ is of class $(\gamma, j)$ if the derivatives of $g$ with respect to $x$ satisfy

\[(2.2) \quad |g^{(i)}(x, \varepsilon)| \leq C(1 + \varepsilon^i e^{-\gamma x/\varepsilon} + \varepsilon^{-i} e^{-\gamma(1-x)/\varepsilon})\]

for $0 \leq i \leq j$, $x \in [0,1]$, where $\gamma$ is some positive constant independent of $x$ and $\varepsilon$.

**Lemma 2.2.** Let $g$ be of class $(\gamma, 0)$. Then the solution $w$ of (2.1) satisfies $|w(x)| \leq C$.

**Proof.** Apply the maximum principle to $-C \pm w(x)$. □
Lemma 2.3. Let \( g \) be of class \((\gamma, 0)\). Then the solution \( w \) of (2.1) satisfies \( |w'(x)| \leq Ce^{-1} \) for \( x \in [0, 1] \).

Proof. From the differential equation (2.1) we have that

\[
(2.3) \quad \left( pe^{-D/e}\left( w' + e^{-1}\left((r/p)^{1/2}\right)w\right)\right)' = e^{-2}e^{-D/e}\left( g + ((rp)^{1/2})e\right),
\]

\[
(2.4) \quad \left( pe^{D/e}\left( w' - e^{-1}\left((r/p)^{1/2}\right)w\right)\right)' = e^{-2}e^{D/e}\left( g - ((rp)^{1/2})e\right),
\]

where

\[
D(x) = \int_{t=0}^{x} (r/p)^{1/2} dt.
\]

Integrate (2.3) from 0 to \( t \), multiply by \( p^{-1}e^{2D/e} \) and then integrate again from \( t = 0 \) to \( t = 1 \). Collecting terms, we get \( |w'(0)| \leq Ce^{-1} \). By integrating (2.4) from 0 to \( x \) and using \( |w'(0)| \leq Ce^{-1} \), we get \( |w'(x)| \leq Ce^{-1} \). \( \square \)

Lemma 2.4. Let \( g \) be of class \((\gamma, 1)\). Then the solution \( w \) of (2.1) satisfies

\[
|w'(x)| \leq C(1 + e^{-\delta}exp(-\delta x/e) + e^{-\delta}exp(-\delta(1 - x)/e))
\]

for \( x \in [0, 1] \), where \( \delta \) is a positive constant depending only on \( p, r, \) and \( \gamma \).

Proof. Differentiate (2.1) to obtain

\[
(2.5) \quad \epsilon^2 v'' - (r/p)v = g' + r'w,
\]

where \( v(x) = pw'(x) \). Applying the maximum principle to (2.5) with the barrier function

\[
z(x) = C_1(exp(-\delta x/e) + exp(-\delta(1 - x)/e)) + C_2
\]

(where \( C_1, C_2, \) and \( \delta \) are suitably chosen constants) and using Lemma 2.3 to bound \( |w'(0)| \) and \( |w'(1)| \), we get the desired bound on \( |w'(x)| \). \( \square \)

Lemma 2.5. Let \( g \) be of class \((\gamma, 2)\). Then the solution \( w(x) \) of (2.1) satisfies

\[
|w''(x)| \leq C(1 + e^{-2}\{exp(-\delta x/e) + exp(-\delta(1 - x)/e)\})
\]

for \( x \in [0, 1] \), where \( \delta \) is a positive constant depending only on \( p, r, \) and \( \gamma \).

Proof. Apply the arguments in Lemmas 2.3 and 2.4 to the differential equation (2.5). \( \square \)

Corollary 2.6. If \( y \) is the solution of (1.1), then

\[
|y^{(i)}(x)| \leq C(1 + \epsilon^{-i}\{exp(-\delta_0 x/e) + exp(-\delta_0(1 - x)/e)\}) \quad \text{for} \quad i = 0, 1, 2
\]

and \( x \in [0, 1] \), where \( \delta_0 \) is some positive constant depending only on \( p \) and \( r \).

The next lemma gives us an asymptotic expansion for the solution \( y \) of (1.1).

Lemma 2.7. The solution \( y(x) \) of (1.1) may be written as

\[
y(x) = -f(x)/r(x) + K_1(\epsilon)exp(-D(x)/\epsilon)
\]

\[
+ K_2(\epsilon)exp(-(D(1) - D(x))/\epsilon) + \epsilon R_0(x),
\]

License or copyright restrictions may apply to redistribution; see http://www.ams.org/journal-terms-of-use
where

\[ |K_1(ε)| \leq C, \quad |K_2(ε)| \leq C, \]
\[ D(x) = \int_{0}^{x} (r(t)/p(t))^{1/2} dt, \]
\[ R_0(x) \text{ satisfies } LR_0(x) = g(x, ε), \quad R_0(0) = R_0(1) = 0, \]
and \( |g(x, ε)| \leq C \) for \( x \in [0, 1] \), \( ε \in (0, 1] \).

**Proof.** Check by substitution. \( \square \)

The final lemma in this section bounds the derivatives of the remainder term \( R_0(x) \).

**Lemma 2.8.** Let \( R_0(x) \) be defined as in Lemma 2.7; then for \( x \in [0, 1] \),
\[ |R_0^{(i)}(x)| \leq Cε^{-i}, \quad i = 0, 1, 2. \]

**Proof.** From Lemma 2.2, \( |R_0(x)| \leq C \). From Lemma 2.3, \( |R_0'(x)| \leq Cε^{-1} \). Now
\[ ε^2(pR_0')' = g(x, ε) + rR_0(x). \]
Thus
\[ |R_0''(x)| \leq Cε^{-2}, \quad 0 \leq x \leq 1. \quad \square \]

3. **Discretizing the Problem.** Divide the interval \([0, 1]\) into \( N \) subintervals, each of length \( h \), and let \( x_j = jh \), \( 0 \leq j \leq N \). Define \([0, 1]^*\) to be \([0, 1] \setminus \{x_j\}_0^N\). As an approximation to the function \( r(x) \), define the piecewise-constant function \( \tilde{r}(x) \) to be
\[ \tilde{r}(x) = \tilde{r}_j = \left( r(x_{j-1}) + r(x_j) \right)/2 \quad \text{for } x \in [x_{j-1}, x_j], \ j = 1, \ldots, N, \]
\[ \tilde{r}(x_N) = \tilde{r}_N. \]
Define \( \tilde{p}(x) \) and \( \tilde{f}(x) \) similarly. Define the operator \( \tilde{L} \) by
\[ \tilde{L}w = ε^2(\tilde{p}w')' - r\tilde{w} \quad \text{for } w \in C^2[0, 1], \]
the derivatives being taken in the sense of distributions.

The next lemma shows that \( \tilde{L} \) satisfies a maximum principle.

**Lemma 3.1.** Let \( w \in C[0, 1] \cap C^2([0, 1]^*) \) and \( \tilde{p}w' \in C[0, 1] \). Suppose \( w(0) \leq 0 \), \( w(1) \leq 0 \), \( \tilde{L}w \geq 0 \) on \([0, 1]^*\). Then \( w \leq 0 \) on \([0, 1]\).

**Proof.** Suppose the conclusion is false. Then there exists \( z \in (0, 1) \) such that
\[ \max_{0 \leq x \leq 1} w(x) = w(z) > 0. \]

**Case (i):** \( z \in [0, 1]^* \). Then \( w''(z) \) exists and \( w''(z) \leq 0 \), hence \( \tilde{L}w(z) = ε^2\tilde{p}w''(z) - \tilde{r}w(z) < 0 \), a contradiction.

**Case (ii):** \( z = x_i \), for some fixed \( i \). Since \( w \in C[0, 1] \), we can choose intervals \((c, x_i)\) and \((x_i, b)\), with \( x_{i-1} < c < x_i \) and \( x_i < b < x_{i+1} \), such that \( w > 0 \) on \((c, b)\).
Now \( \tilde{L}w = ε^2(\tilde{p}w')' - \tilde{r}w \geq 0 \) on \((c, x_i) \cup (x_i, b)\). Thus \( (\tilde{p}w')' > 0 \) on \((c, x_i) \cup (x_i, b)\).

(a) Suppose \( \tilde{p}w'(z) \geq 0 \). Then, since \( \tilde{p}w' \in C[0, 1] \) and \( (\tilde{p}w')' > 0 \) on \((x_i, b)\), this implies that \( \tilde{p}w'(x) > 0 \) on \((x_i, b)\), hence \( w'(x) > 0 \) on \((x_i, b)\). Then \( w \) cannot have a maximum at \( x_i \). Contradiction.

(b) Similarly, if \( \tilde{p}w'(z) < 0 \), it follows that \( w' < 0 \) on \((c, x_i)\), hence \( w \) cannot have a maximum at \( x_i \). Contradiction. \( \square \)
Define each test function $\psi_k$, $k = 1, \ldots, N - 1$, to be the solution of

\begin{equation}
(3.1) \quad \bar{L}\psi_k = 0 \quad \text{on } [0,1]^*, \quad \psi_k(x_j) = \delta_{k,j}, \quad j = 0, \ldots, N,
\end{equation}

where $\delta_{k,j}$ is the Kronecker delta.

Choose the trial functions $\phi_i$, $i = 0, \ldots, N$, to satisfy $\phi_i(x_j) = \delta_{i,j}$, $j = 0, \ldots, N$, with the support of each $\phi_i(x)$ the one or two subintervals containing $x_i$.

The Petrov-Galerkin approximation is

\begin{equation}
(3.2) \quad u(x) = \sum_{i=0}^{N} u_i \phi_i(x),
\end{equation}

where the $u_i$ are determined from the system of equations

\begin{equation}
(3.3) \quad \bar{B}_e(u, \psi_j) = (\bar{f}, \psi_j), \quad j = 1, \ldots, N - 1,
\end{equation}

where

\[ \bar{B}_e(v, w) = (-e^2 \bar{p}v', w') - (\bar{r}v, w), \quad v, w \in H^1(0,1) \]

and

\[ (v, w) = \int_0^1 v(x)w(x)\,dx, \quad v, w \in L^2(0,1). \]

\textbf{Lemma 3.2.} The difference scheme (3.3) has a unique solution.

\textit{Proof.} The difference scheme (3.3) may be written as

\[ \epsilon^2 h^{-2}Au = Bf, \]

i.e.,

\[ \epsilon^2 h^{-2}[a_{j-1}^+ u_{j-1} + a_j^0 u_j + a_{j+1}^+ u_{j+1}] = b_j^+ \bar{f}_j + b_{j+1}^- \bar{f}_{j+1}, \quad j = 1, \ldots, N - 1, \]

where

\[ a_{j-1}^+ = h\bar{p}_j \psi_j'(x_{j-1}), \quad a_j^+ = -h\bar{p}_{j+1} \psi_j'(x_{j+1}), \quad a_j^0 = -h\bar{p}_j \psi_j'(x_j) + h\bar{p}_{j+1} \psi_j'(x_j), \]

\[ b_j^- = h^{-1}(1, \psi_j)_j, \quad b_j^+ = h^{-1}(1, \psi_j)_{j+1} \quad \text{and} \quad (u, v)_j = \int_{x_j-1}^{x_j} u(x)v(x)\,dx. \]

By explicitly solving for $\psi_j(x)$ from (3.1), the reader can easily verify that

\[ a_j^- > 0, \quad a_j^+ > 0 \quad \text{and} \quad a_j^0 < -a_j^- - a_j^+. \]

This implies that the matrix $-A$ is an $M$-matrix and hence invertible (see Varga [13]). \qed

\textbf{Remark.} The difference scheme (3.3) is written out explicitly in Section 7.

\textbf{4. The Discretized Green's Function.} We associate a discretized Green’s function $G_j(x)$ with each node $x_j$, $j = 1, \ldots, N - 1$. Define each $G_j(x)$ in the sense of distributions by

\begin{equation}
(4.1) \quad \bar{L}G_j(x) = \epsilon^2 (\bar{p}G_j)'(x) - \bar{r}G_j(x) = \delta(x - x_j), \quad G_j(0) = G_j(1) = 0,
\end{equation}

where $\delta(\cdot)$ is the Dirac $\delta$-distribution.
In the classical sense, each $G_j(x)$ is defined by

(4.2a) $G_j \in C[0,1]$,

(4.2b) $G_j(0) = G_j(1) = 0$,

(4.2c) $G''_j$ exists and is continuous on $[0,1]^*$,

(4.2d) $\epsilon^2 \bar{p}G''_j - \bar{r}G_j = 0$ on $[0,1]^*$,

(4.2e) $\lim_{x \to x_i} \epsilon^2 \bar{p}G'_j(x) - \lim_{x \to x_i} \epsilon^2 \bar{p}G'_j(x) = \delta_{i,j}, \quad i = 1, \ldots, N - 1.$

**Lemma 4.1.** (i) $G_j(x)$ is well-defined and lies in the test space spanned by the test functions defined in (3.1).

(ii) $G_j(x) \leq 0$ on $[0,1]$.

**Proof.** (i) We must show that there exists a unique choice of $\{\lambda_k\}_{k=1}^{N-1}$ such that

$$G_j(x) = \sum_{k=1}^{N-1} \lambda_k \psi_k(x).$$

Now for each $i$ we require

$$\sum_{k=1}^{N-1} \lambda_k \bar{B}_k(\phi_i, \psi_k) = \delta_{i,j}, \quad i = 1, \ldots, N - 1,$$

for the unknowns $\lambda_1, \ldots, \lambda_{N-1}$. The matrix of this system is the transpose of the matrix associated with the difference scheme (3.3), which from Lemma 3.2 is known to be invertible.

(ii) The matrix in (3.3) is the negative of an $M$-matrix, so its inverse has all nonpositive entries (see Varga [13]). Thus $\lambda_k \leq 0$, $k = 1, \ldots, N - 1$. Now $\psi_k > 0$ on $(x_{k-1}, x_k)$. Since $G_j(x) = \sum_{k=1}^{N-1} \lambda_k \psi_k(x)$, we have $G_j \leq 0$ on $[0,1]$. □

**Theorem 4.2.** For $x \in [0,1]$, $|G_j(x)| \leq Ce^{-\gamma}|x - x_j|/e$, where $\gamma = \min((r(x)p(x))^{1/2})/\max(p(x))$.

**Proof.** Set $\omega(x) = -\{\exp(-(\beta \xi)^{1/2})/|x - x_j|/(\bar{p}(x)e))\}/(2(\beta \xi)^{1/2}/e)$. Note that $\bar{p} \omega'(x^-) = -1/(2e^2)$, $\bar{p} \omega(x^+) = 1/(2e^2)$. So $\bar{p} \omega(x)$ has a jump of $e^{-2}$ at $x_j$. Let $z = \omega - G_j$ on $[0,1]$. Then $z \in C[0,1]$, $z \in C^2([0,1]^*)$ and $\bar{p}z' \in C[0,1]$ (jumps cancel at $x = x_j$). Thus we are able to apply the maximum principle for $\bar{L}$, given in Lemma 3.1. Now $z(0) < 0$ and $z(1) < 0$. On $[0,1]^*$,

$$\bar{L}z = \epsilon^2 (\bar{p} \omega') - (\beta \xi \omega)/\bar{p} + (\beta \xi/\bar{p} - \bar{r}) \omega - \bar{L}G_j = (\beta \xi - \bar{r}) \omega/\bar{p} > 0.$$ 

By Lemma 3.1, $z \leq 0$ on $[0,1]$. Thus $G_j(x) \geq \omega(x)$, but from Lemma 4.1 $G_j(x) \leq 0$. Thus $|G_j(x)| \leq |\omega(x)|$. The result follows. □

The next result bounds the derivative of the Green’s function.

**Theorem 4.3.** $|G_j'(t)| \leq Ce^{-\gamma}|x - x_j|/e$ for $t \in [0,1] \setminus \{x_j\}$, where $\gamma$ is as in Theorem 4.2.
Proof. From the definition of $G_j(t)$ in (4.1), we have

$$\left( \bar{p} \exp(-D(t)/\epsilon) \left[ G_j' + (\bar{r}/\bar{p})^{1/2} \epsilon G_j \right] \right)' = \epsilon^{-2} \exp(-D(x)/\epsilon) \left[ \delta(x - x_j) + (\sqrt{\bar{p}})' \epsilon G_j \right],$$

(4.3)

$$\left( \bar{p} \exp(\bar{D}(t)/\epsilon) \left[ G_j' - (\bar{r}/\bar{p})^{1/2} \epsilon G_j \right] \right)' = \epsilon^{-2} \exp(\bar{D}(x)/\epsilon) \left[ \delta(x - x_j) - (\sqrt{\bar{p}})' \epsilon G_j \right],$$

(4.4)

where $\bar{D}(x) = \int_0^x \left( \bar{r}(t)/\bar{p}(t) \right)^{1/2} dt$.

Integrate (4.3) from 0 to $t$, multiply by $(\bar{p})^{-1} \exp(2D(t)/\epsilon)$ and then integrate again from $t = 0$ to $t = 1$. Collecting terms, we get

$$|G_j(0)| \leq C \epsilon^{-2} \exp(-D(x_j)/\epsilon) + C \epsilon^{-2} |I|,$$

where

$$I = \int_0^t \left( \bar{p}(s) \right)^{-1} \exp(-2(\bar{D}(s) - \bar{D}(t))/\epsilon) \int_0^s \exp(-\bar{D}(x)/\epsilon) \epsilon G_j(\sqrt{\bar{p}})' ds dt.$$

The integral $I$ equals

$$\sum_{i=1}^N \sum_{k=1}^{N-1} \int_{x_{i-1}}^{x_i} \left( \bar{p}(s) \right)^{-1} \exp(-2(\bar{D}(s) - \bar{D}(t))/\epsilon) \exp(-\bar{D}(x_k)/\epsilon)$$

$$\times \epsilon G_j(x_k) \left\{ \sqrt{\bar{p}}(x_k^+) - \sqrt{\bar{p}}(x_k^-) \right\} dt.$$

Now for any set of numbers $\{b_{ik}\}$, it is easy to show by induction on $N$ that

$$\sum_{i=1}^N \sum_{k=1}^{N-1} b_{ik} = \sum_{k=1}^{N-1} \sum_{i=k+1}^N b_{ik}.$$

Applying this above yields

$$I = \sum_{k=1}^{N-1} \exp(-\bar{D}(x_k)/\epsilon) \epsilon G_j(x_k) \left\{ \sqrt{\bar{p}}(x_k^+) - \sqrt{\bar{p}}(x_k^-) \right\}$$

$$\times \sum_{i=k+1}^N \int_{x_{i-1}}^{x_i} \left( \bar{p}(s) \right)^{-1} \exp(-2(\bar{D}(s) - \bar{D}(t))/\epsilon) dt.$$

Thus,

$$|I| \leq \sum_{k=1}^{N-1} C \exp(-\gamma x_k/\epsilon) |G_j(x_k)| \int_{x_k}^1 \epsilon^{-1} \exp(-2(\bar{D}(1) - \bar{D}(t))/\epsilon) dt.$$

Bounding each integral in the sum by $C$ and using the bound on $|G_j(x_k)|$ from Theorem 4.2, we get

$$|I| \leq C \left[ \sum_{k=1}^j \exp(-\gamma x_k/\epsilon) + \sum_{k=1}^{N-1} \exp(-\gamma (2x_k - x_j)/\epsilon) \right].$$

$$\leq C \sum_{k=1}^{N-1} \exp(-\gamma x_k/\epsilon) \leq C \exp(-\gamma x_j/\epsilon), \quad \text{since } hN = 1.$$

We have thus shown that

$$|G_j(0)| \leq C \epsilon^{-2} \exp(-\gamma x_j/\epsilon).$$
We will use this to bound $G_i(t)$ on $[0, x_i)$. Let $t \in [x_i, x_{i-1})$, where $i \leq j$. Integrate (4.4) from 0 to $t$ and multiply by $(\bar{p}(t))^{-1}\exp(-\bar{D}(t)/\epsilon)$. Thus, collecting terms, we get

$$|G_i'(t)| \leq Ce^{-2}\exp(-\gamma(x_j - t)/\epsilon) + Ce^{-2}\left|\int_0^t \exp\left(-\left(\bar{D}(t) - \bar{D}(s)/\epsilon\right)\right)eG_j(s)(\sqrt{p})'(s)\,ds\right| \leq Ce^{-2}\exp(-\gamma(x_j - t)/\epsilon)$$

(4.6)

$$+ Che^{-2}\sum_{k=1}^{i-1} \exp(-\gamma(t - x_j)/\epsilon)\exp(-\gamma(x_j - x_k)/\epsilon)$$

$$= Ce^{-2}\exp(-\gamma(x_j - t)/\epsilon)$$

$$+ Che^{-2}\exp(-\gamma(x_j - t)/\epsilon)\sum_{k=1}^{i-1} \exp(-2\gamma(t - x_k)/\epsilon)$$

$$\leq Ce^{-2}\exp(-\gamma(x_j - t)/\epsilon).$$

By symmetry arguments, we now extend this bound to $(x_i, 1]$. For $0 \leq x \leq 1$, set $F_j(x) = G_j(1 - x)$, $\tilde{r}_j(x) = \tilde{r}(1 - x)$ and $\tilde{p}_j(x) = \tilde{p}(1 - x)$.

Then

$$e^2(\bar{p}_j F_j)'(x) - \tilde{r}_j(x) F_j(x) = e^2(\bar{p}G_j)'(1 - x) - \tilde{r}(1 - x)G_j(1 - x)$$

$$= \delta(1 - x - x_j) = \delta(x - (1 - x_j)).$$

That is, $F_j$ satisfies the same sort of equation as (4.1) (of course $F_j(0) = F_j(1) = 0$).

Note, however, that we have $\delta(x - (1 - x_j))$ instead of $\delta(x - x_j)$, as we had for $G_j(x)$. From (4.6), we therefore have

$$|G_j'(1 - y)| = |F_j'(y)| \leq Ce^{-2}\exp(-\gamma(1 - x_j - y)/\epsilon), \quad 0 < y < 1 - x_j.$$  

Let $x = 1 - y$. Then

$$|G_j'(x)| \leq Ce^{-2}\exp(-\gamma(x - x_j)/\epsilon)$$

for $x_j < x < 1$, which together with (4.6) completes the proof. □

**Corollary 4.4.** (a) $|G_j(x_i) - G_j(x_{i-1})| \leq Che^{-2}\exp(-\gamma(x_j - x_i)/\epsilon)$ for $1 \leq i < j$.

(b) $|G_j(x_i) - G_j(x_{i-1})| \leq Che^{-2}\exp(-\gamma(x_{i-1} - x_j)/\epsilon)$ for $j < i \leq N$.

**Proof. (a)**

$$|G_j(x_i) - G_j(x_{i-1})| = h\left|G_j'(-\eta_i)\right|, \quad x_{i-1} < \eta_i < x_i,$$

$$\leq Che^{-2}\exp(-\gamma(x_j - \eta_i)/\epsilon) \quad \text{for } i \leq j,$$

$$\leq Che^{-2}\exp(-\gamma(x_j - x_i)/\epsilon), \quad \text{since } \eta_i < x_i.$$

(b) Similarly. □

**5. Estimating the Nodal Error.** The error at each node $x_j$ can be given explicitly in terms of the discretized Green's function.
Theorem 5.1. Let \( y(x) \) be the solution of problem (1.1). Let \( u(x) \) be our approximation defined in (3.2) and (3.3). Then

\[
y(x_j) - u(x_j) = (f - \tilde{f}, G_j) + \left( e^2 (p - \bar{p}) y', G_j' \right) + (r - \tilde{r}, y G_j)
\]

for \( j = 1, \ldots, N - 1 \).

Proof.

\[
y(x_j) - u(x_j) = (y - u, \delta(x - x_j)) = (y - u, \bar{G}j) = B_t(y, G_j) - B_y(u, G_j)
\]

by (3.3) and Lemma 4.1(i)

\[
= B_t(y, G_j) + \left( e^2 (p - \bar{p}) y', G_j' \right) + (r - \tilde{r}, y G_j)
\]

\[
= (f, G_j) - (\tilde{f}, G_j) + \left( e^2 (p - \bar{p}) y', G_j' \right) + (r - \tilde{r}, y G_j). \quad \square
\]

On the interval \([x_{i-1}, x_i] \) we may write the Green's function in the form

\[
G_j(x) = a_i \sinh(\alpha_i(x - x_{i-0.5})/h) + b_i \cosh(\alpha_i(x - x_{i-0.5})/h),
\]

where

\[
a_i = \frac{(G_j(x_i) - G_j(x_{i-1}))}{2\sinh(\alpha_i/2)},
\]

\[
b_i = \frac{(G_j(x_i) + G_j(x_{i-1}))}{2\cosh(\alpha_i/2)},
\]

\[
x_{i-0.5} = (x_{i-1} + x_i)/2 \quad \text{and} \quad \alpha_i = (\tilde{r}_i/\tilde{p}_i)^{1/2}h^{-1}.
\]

The following term will arise repeatedly throughout the error analysis:

\[
\tau_i = \int_{x_{i-1}}^{x_i} \left[ (x - x_{i-0.5}) \sinh(\alpha_i(x - x_{i-0.5})/h) \right] /[2 \sinh(\alpha_i/2)] \, dx.
\]

The next lemma is a technical lemma needed in the analysis of Lemma 5.3.

Lemma 5.2 (i) \( |\tau_i| \leq Ch^2 \),

(ii) \( |\tau_i| \leq Ch\epsilon \),

(iii) \( |\tau_{i+1} - \tau_i| \leq Ch^2 \epsilon \),

(iv) \( |\tau_i - \tau_j| \leq Ch^2 |x_i - x_j| \),

where \( \tau_i \) is defined in (5.3) and \( 1 \leq i, j \leq N \).

Proof. (i) Setting \( y = 2(x - x_{i-0.5})/h \),

\[
\tau_i = \left( h^2/8 \right) \int_{-1}^{1} \left[ y \sinh(\alpha_i y/2) \right] [\sinh(\alpha_i/2)] \, dy.
\]

Thus \( |\tau_i| \leq Ch^2 \).

(ii) Evaluating the integral in (i), we get

\[
|\tau_i| = \left| \left( h/\alpha_i \right)^2 \left( (\alpha_i/2) \coth(\alpha_i/2) - 1 \right) \right| \leq Ch\epsilon,
\]

since \( |x \coth(x) - 1| \leq Cx \) for all \( x \).

(iii) Using (ii), we get

\[
\tau_{i+1} - \tau_i = h^2 (\alpha_{i+1}^2 - \alpha_i^2) \left( (\alpha_{i+1}/2) \coth(\alpha_{i+1}/2) - 1 \right)
\]

\[
+ h^2 \alpha_i^2 \left( (\alpha_{i+1}/2) \coth(\alpha_{i+1}/2) - (\alpha_i/2) \coth(\alpha_i/2) \right).
\]

License or copyright restrictions may apply to redistribution; see http://www.ams.org/journal-terms-of-use
Now \(|x \coth(x) - 1| \leq Cx\) and \(|x \coth(x) - y \coth(y)| \leq |x - y|\), since \(|(x \coth(x))'| \leq 1\) for all \(x\). Thus \(|\tau_{i+1} - \tau_i| \leq C h^2 e\).

(iv) Fix \(i, j \in \{1, \ldots, N\}\). Let
\[
    u(y) = \frac{\sinh(\alpha_j y/2)}{\sinh(\alpha_j/2)} \quad \text{and} \quad v(y) = \frac{\sinh(\alpha_j y/2)}{\sinh(\alpha_j/2)},
\]

for \(0 \leq y \leq 1\). Let \(M_j w = w'' - (\alpha_j^2/4) w\), for \(w \in C^2[0,1]\). Note that \(M_i\) satisfies a maximum principle and \(M_i u = 0\). Apply the maximum principle for \(M_i\) to
\[
z(y) = -C|x_i - x_j| \pm (u - v)(y), \quad 0 \leq y \leq 1.
\]

Now \(z(0) = z(1) = -C|x_i - x_j| \leq 0\) and
\[
    M_i z = C(\alpha_i^2/4)|x_i - x_j| \pm (\alpha_i^2 - \alpha_j^2) v/4 \geq 0
\]
for suitably large \(C\), since \(|v| \leq 1\). Thus \(z \leq 0\). That is, \(|u - v| \leq C|x_i - x_j|\). Thus
\[
    |\tau_i - \tau_j| = \left(\frac{h^2}{4}\right) \left| \int_0^1 y(u(y) - v(y)) \, dy \right| \leq C h^2 |x_i - x_j|.
\]

Note that
\[
\int_{x_{i-1}}^{x_i} (x - x_{i-0.5}) \cosh(\alpha_i(x - x_{i-0.5})/h) \, dx = 0,
\]
since the integrand is an odd function about \(x = x_{i-0.5}\).

**Lemma 5.3** Let \(G_j(x)\) be the solution of (4.1). If \(k, q, w\) are functions defined on \([0,1]\) such that \(|k^{(i)}| \leq C\) for \(i = 0, 1, 2\), \(|q^{(i)}| \leq C\) for \(i = 0, 1\), \(|w^{(i)}| \leq C \varepsilon^{-i}\) for \(i = 0, 1\), \(\bar{k}(x) = \frac{k(x_i) + k(x_{i-1})}{2}\) for \(x \in [x_{i-1}, x_i]\) and \(D(x) = \int_{\tau_{i-1}}^{\tau_i} \frac{r(t)/p(t)}{p(t)}^{1/2} \, dt\), then

(i) \(|(k - \bar{k}, q G_j)| \leq C h^2\),
(ii) \(|(k - \bar{k}, q \exp(-D/\varepsilon)G_j)| \leq C h^2\),
(iii) \(|(k - \bar{k}, q \exp(-D(1) - D(x))/\varepsilon G_j)| \leq C h^2\),
(iv) \(|(k - \bar{k}, \varepsilon^2 q G_j')| \leq C h^2\),
(v) \(|(k - \bar{k}, \varepsilon q \exp(-D/\varepsilon)G_j')| \leq C h^2\),
(vi) \(|(k - \bar{k}, \varepsilon q \exp(-D(1) - D(x))/\varepsilon G_j')| \leq C h^2\),
(vii) \(|(k - \bar{k}, \varepsilon^2 w G_j')| \leq C h^2\).

**Proof.** For \(x \in [x_{i-1}, x_i]\),
\[
k(x) - \bar{k}(x) = k'(x_{i-0.5})(x - x_{i-0.5}) + O(h^2), \quad q(x) = q(x_{i-0.5}) + O(h).
\]

Let \(s(x_i) = k'(x_{i-0.5})q(x_{i-0.5})\) and set
\[
    (u, v) = \int_{x_{i-1}}^{x_i} u(x) v(x) \, dx \quad \text{for} \quad u, v \in L^2[0,1].
\]

(i) Theorem 4.2 implies that (1, \(|G_j|\)) \leq C. Using this and (5.2), (5.3), and (5.4), we have
\[
    (k - \bar{k}, q G_j) = \sum_{i=1}^{N} s(x_i) \tau_i (G_j(x_i) - G_j(x_{i-1})) + O(h^2)
\]
\[
    = \sum_{i=1}^{N-1} (\xi_i - \xi_{i-1}) G_j(x_i) + O(h^2),
\]
where we put \(\xi_i = s(x_i)\) \(\tau_i\) and used \(G_j(x_0) = G_j(x_N) = 0\). By Lemma 5.2, we have
\[
    |\xi_i - \xi_{i+1}| \leq |s(x_i) - s(x_{i+1})| |\tau_i| + |s(x_{i+1})| |\tau_i - \tau_{i+1}|
\]
\[
    \leq C \min(h^2, h \varepsilon) + C \min(h^3, h^2 \varepsilon) \leq C h^2 \min(h, \varepsilon).
\]
Combining this with the estimate $|G_j(x_i)| \leq C \varepsilon^{-1} \exp(-\gamma h|j - i|/\varepsilon)$, which follows from Theorem 4.2, we get
\[
\left| \sum_{i=1}^{N} (\xi_i - \xi_{i+1}) G_j(x_i) \right| \leq C h^2 \min(h/\varepsilon, 1) \sum_{i=1}^{N-1} \exp(-\gamma h|j - i|/\varepsilon) \leq C h^2 \min(1/(1 - \varepsilon^\lambda), 1/(1 - \varepsilon^\lambda))
\]
with $\lambda = h/\varepsilon$. Since $\lambda/(1 - \varepsilon^{-\lambda}) \leq C$ for $0 < \lambda \leq 1$ and $1/(1 - \varepsilon^{-\lambda}) \leq C$ for $\lambda > 1$, we have
\[
\left| \sum_{i=1}^{N} (\xi_i - \xi_{i+1}) G_j(x_i) \right| \leq C h^2,
\]
which completes the proof of (i).

(ii) Let $\bar{D}(x) = \int_{s=0}^{x} (\bar{\alpha}(t)/\bar{\beta}(t))^{1/2} dt$. We have
\[
\left( k - \bar{k}, q \exp(-\bar{D}/\varepsilon) G_j \right) = \left( k - \bar{k}, q \exp(-\bar{D}/\varepsilon) G_j \right) + O(h^2),
\]
since $|k - \bar{k}| \leq Ch(1, |G_j|) \leq C$, $|q| \leq C$ and
\[
|\exp(-D(x)/\varepsilon) - \exp(-\bar{D}(x)/\varepsilon)| \leq Ch \varepsilon^{-1} \exp(-\gamma x/\varepsilon) \leq C h.
\]
Hence,
\[
\left( k - \bar{k}, q \exp(-\bar{D}/\varepsilon) G_j \right) = \sum_{i=1}^{N} s(x_i) \exp(-\bar{D}(x_{i-0.5})/\varepsilon) \left( x - x_{i-0.5}, e^{-\eta_i(x - x_{i-0.5})/h} G_j \right) + O(h^2).
\]
On the interval $[x_{i-1}, x_i]$,
\[
G_j(x) = \{(a_i + b_i)/2\} \exp(\alpha_i(x - x_{i-0.5})/h) + \{(b_i - a_i)/2\} \exp(-\alpha_i(x - x_{i-0.5})/h),
\]
where $a_i$ and $b_i$ are as defined in (5.2). Using $(1, x - x_{i-0.5}) = 0$, we get
\[
\left( k - \bar{k}, q \exp(-\bar{D}/\varepsilon) G_j \right) = \sum_{i=1}^{N} s(x_i) (a_i - b_i) \exp(-\bar{D}(x_{i-0.5})/\varepsilon) \sinh(\alpha_i) \tau_i^* + O(h^2),
\]
where $\tau_i^* = (x - x_{i-0.5}, (\sinh(2\alpha_i(x - x_{i-0.5})/h))/2 \sinh(\alpha_i)) \left[ \exp(-y) = \cosh(y) - \sin(y) \right. \left. - \sinh(y) \right]$ and (5.4). Let
\[
c_i = (a_i - b_i) \exp(-\bar{D}(x_{i-0.5})/\varepsilon) \sinh(\alpha_i).
\]
With this notation,
\[
\left( k - \bar{k}, q \exp(-\bar{D}/\varepsilon) G_j \right) = \sum_{i=1}^{N} s(x_i) c_i \tau_i^* + O(h^2).
\]
From the definition of $a_i$ and $b_i$,
\[
c_i = \exp(-\bar{D}(x_i)/\varepsilon) G_j(x_i) - \exp(-\bar{D}(x_{i-1})/\varepsilon) G_j(x_{i-1}) \equiv \eta_i - \eta_{i-1}.
\]
Consequently,
\[
\sum_{i=1}^{N} s(x_i) c_i \tau_i^* = \sum_{i=1}^{N} s(x_i) (\eta_i - \eta_{i-1}) \tau_i^* = \sum_{i=1}^{N-1} \left( s(x_i) \tau_i^* - s(x_{i+1}) \tau_{i+1}^* \right) \eta_i.
\]
since $G_j(x_0) = G_j(x_N) = 0$. Note that Lemma 5.2 can be applied to $\tau_i^*$ and that $|\eta_i| \leq |G_j(x_i)|$ holds. Hence we get as in part (i),
\[
\left| \sum_{i=1}^{N} s(x_i) c_i \tau_i^* \right| \leq Ch^2,
\]
which completes the proof of (ii).

(iii) We have
\[
\left( k - \bar{k}, q \exp((-D(1) - D(x))/\varepsilon) G_j(x) \right) = \left( k_1 - \bar{k}_1, q_1 \exp(-D_1(t)/\varepsilon) F_j(t) \right),
\]
where $k_i(t) = k(1 - t)$, $\bar{k}_i(t) = \bar{k}(1 - t)$, $q_i$, $r_i$, and $p_1$ defined similarly,
\[
D_1(t) = \int_0^t \left( r_1(s)/p_1(s) \right)^{1/2} ds
\]
and $F_j(t)$ is defined as in the last part of Theorem 4.3. Since $F_j(t)$ satisfies the same sort of differential equation as $G_j(x)$ did, we can use (ii) to get the result.

(iv) From (5.2), on the interval $(x_{i-1}, x_i)$,
\[
G_j'(x) = (\alpha_i a_i/h) \cosh(\alpha_i(x - x_{i-0.5})/h) + (\alpha_i b_i/h) \sinh(\alpha_i(x - x_{i-0.5})/h).
\]
Thus
\[
\left| (e^2(k - \bar{k}), qG_j') \right| = \left| \sum_{i=1}^{N} e^2 h^{-1} \alpha_i s(x_i) t_i \left\{ G_j(x_i) + G_j(x_{i-1}) \right\} \tanh(\alpha_i/2) \right| + O(h^2)
\]
\[
\leq Ch^2 e \sum_{i=1}^{N} \left| G_j(x_i) + G_j(x_{i-1}) \right| (1 - e^{-\alpha_i}) + O(h^2),
\]
since, by Lemma 5.2, $|\tau_i| \leq Ch^2$. From Theorem 4.2, we have
\[
\left| G_j(x_{i-1}) + G_j(x_i) \right| \leq Ce^{-1} \begin{cases} \exp(-\gamma |x_j - x_i|/\varepsilon), & i \leq j, \\ \exp(-\gamma |x_{i-1} - x_j|/\varepsilon), & i > j. \end{cases}
\]
Using this, we get the result.

(v) Follow the argument in (ii), replacing $G_j$ by $eG_j'$, and note that
\[
eG_j'(x) = (e\alpha_i/(2h)) \left\{ (a_i + b_i)e^{\alpha_i(x - x_{i-0.5})/h} + (a_i - b_i)e^{-\alpha_i(x - x_{i-0.5})/h} \right\}.
\]

(vi) Use the transformation given in (iii) and then use (v).

(vii) Write $w(x) = w(x_{i-0.5}) + (w(x) - w(x_{i-0.5}))$. Thus,
\[
\left( e^2(k - \bar{k}), wG_j' \right) = \sum_{i=1}^{N} k'(x_{i-0.5}) \left( w(x) - w(x_{i-0.5}), (x - x_{i-0.5})e^2G_j' \right)_i
\]
\[
+ O(h^2) \quad \text{by (iv)}.
\]
Therefore,
\[
\left| (k - \bar{k}, e^2wG_j') \right| \leq Ch^2 \max |w'(x)| \left( 1, e^2|G_j'| \right) + Ch^2.
\]
Now $(1, e|G_j'|) \leq C$ by Theorem 4.3. Thus
\[
\left| (k - \bar{k}, e^2wG_j') \right| \leq Ch^2 e \max |w'(x)| + Ch^2 \leq Ch^2. \quad \square
THEOREM 5.4. Let \( y(x) \) be the solution of problem (1.1). Let \( u(x) \) be the approximation defined in (3.2) and (3.3). Then
\[
\max_{0 \leq i \leq N} |y(x_i) - u(x_i)| \leq C h^2.
\]

Proof. Substitute the asymptotic expansion given in Lemma 2.7 into the closed form expression for the nodal error given in Theorem 5.1 and use Lemma 5.3 to bound each term. The nine terms involved are
\[
y(x_j) - u(x_j) = f(\tilde{f}, G_j) + (r - \tilde{r}, - (f/r) G_j)
+ e^2 (p - \tilde{p}, - (f/r) G_j) + (r - \tilde{r}, K_1 e^{-D(x)/\varepsilon} G_j)
- e (p - \tilde{p}, K_1 (r/p)^{1/2} e^{-D(x)/\varepsilon} G_j) + (r - \tilde{r}, K_2 e^{-(D(1) - D(x))/\varepsilon} G_j)
+ e (p - \tilde{p}, K_2 (r/p)^{1/2} e^{-(D(1) - D(x))/\varepsilon} G_j) + (r - \tilde{r}, \varepsilon R_0 G_j)
+ e^2 (p - \tilde{p}, R_0 G_j).
\]
The last two integrals need the bounds given in Lemma 2.8. \( \square \)

6. A Uniform Global Error Estimate. As in O’Riordan [9], we choose the trial functions in such a way that, “close” to a boundary layer, they mirror the shape and direction of that boundary layer. For notational convenience, we will take \( N \) to be even. Define the trial functions \{\phi_i\}_{i=0}^N by
\[
\begin{align*}
\bar{L}_1 \phi_i &= e^2 \bar{p} \phi_i'' + \varepsilon (\bar{p})^{1/2} \phi_i' = 0 \text{ on } [0,0.5] \cap [0,1]^*, \\
\bar{L}_2 \phi_i &= e^2 \bar{p} \phi_i'' - \varepsilon (\bar{p})^{1/2} \phi_i' = 0 \text{ on } [0.5,1] \cap [0,1]^*, \\
\phi_i(x_j) &= \delta_{i,j}, \quad j = 0, \ldots, N.
\end{align*}
\]

THEOREM 6.1. If the trial and test functions are chosen as in (6.1) and (3.1), respectively, then
\[
\|y - u\|_\infty \leq C h,
\]
where \( y \) is the solution of (1.1) and \( u \) is the approximation defined in (3.2) and (3.3).

Proof. (a) Let \( x \in (x_{i-1}, x_i) \), where \( i \leq N/2 \) is fixed.
\[
\bar{L}_1 y = e^2 \bar{p} y'' + \varepsilon (\bar{p})^{1/2} y'
= e^2 p y'' + \varepsilon (r p)^{1/2} y' + e^2 (\bar{p} - p) y'' - (\sqrt{r p} - \sqrt{\bar{p}}) \varepsilon y'
= f + ry + \varepsilon (r p)^{1/2} y' - e^2 (\bar{p} - p) y'' + (\sqrt{r p} - \sqrt{\bar{p}}) \varepsilon y'.
\]
Using the bounds from Corollary 2.6,
\[
|\bar{L}_1 y| \leq |f + ry + \varepsilon (r p)^{1/2} y'| + C \varepsilon + C e^{-\delta_1 x/\varepsilon},
\]
since \( \exp(-\delta_1 (1 - x)/\varepsilon) \leq \exp(-\delta_1 x/\varepsilon) \) for \( x \leq 0.5 \).
Substituting the asymptotic expansion for \( y \) from Lemma 2.7, we get
\[
f + ry + \varepsilon (r/p)^{1/2} y' = 2K_2 e^{-(D(1) - D(x))/\varepsilon} + e k(x),
\]
where \( |k(x)| = |(\varepsilon R_0 - (f/r)'(r p)^{1/2} + r R_0| \leq C \). Therefore,
\[
|f + ry + \varepsilon (r p)^{1/2} y'| \leq C \varepsilon (1 + e^{-e^{-y/2\varepsilon}}) \quad \text{since } x \leq 0.5
\leq C \varepsilon.
\]
Thus \( |\bar{L}_1 y| \leq Ce + Che^{-\delta x^2/\epsilon} \). Set \( z(x) = C(x - x_i - h) - Che^{-\gamma x^2/\epsilon} \pm (y - u) \), where the positive constants \( C, \gamma \) are to be chosen. Now for \( C \) sufficiently large, Theorem 5.4 implies that \( z(x_{i-1}) \leq 0 \) and \( z(x_i) \leq 0 \). Also,

\[
\bar{L}_1 z = Ce((\bar{r}/\bar{p})^{1/2} + \bar{p}C\gamma \left((\bar{r}/\bar{p})^{1/2} - \gamma \right) e^{-\gamma x^2/\epsilon} \pm \bar{L}_1 y.
\]

Now \( |\bar{L}_1 y| \leq Ce + Che^{-\delta x^2/\epsilon} \). Hence we can choose \( C \) and \( \gamma \) such that \( \bar{L}_1 z > 0 \).

Since \( \bar{L}_1 \) satisfies a maximum principle (see Protter and Weinberger [8]), we have

\[
z \leq 0 \text{ on } [x_{i-1}, x_i], \text{ i.e., } |y - u| \leq Ch \text{ on } [x_{i-1}, x_i], \text{ } i \leq N/2.
\]

(b) Similarly for \( x \in (x_{i-1}, x_i) \), where \( i > N/2 \) is fixed, use the maximum principle for \( \bar{L}_2 \) applied to the barrier function

\[
z(x) = C(x, x - 2h) - Che^{-\gamma(1-x^2)/\epsilon} \pm (y - u) \quad \text{for } x \in [x_{i-1}, x_i]. \quad \square
\]

7. Numerical Experiments. In this section, we present some numerical results which illustrate Theorem 5.4. All computations were performed in Fortran double precision on a VAX 11/780 at University College, Cork. The authors are indebted to Dr. Jeanne Ng-Stynes for these results.

The difference scheme (3.3) may be written in the form

\[
e^2h^{-2}\left\{a_j^- u_{j-1}^- + a_j^0 u_j + a_j^+ u_{j+1}^-\right\} = c_j f_{j-1}^- + c_j^0 f_j + c_j^+ f_{j+1}^-,
\]

where

\[
a_j^- = \bar{p}_j^\alpha (a_j), \quad a_j^+ = \bar{p}_j^{\alpha+1} (a_{j+1}), \quad a_j^0 = -\bar{p}_j (a_j) - \bar{p}_j (a_{j+1}),
\]

\[
c_j^- = \sigma (a_j)(2\sigma (a_{j/2}))^{-2}, \quad c_j^+ = \sigma (a_{j+1})(2\sigma (a_{j+1/2}))^{-2},
\]

\[
c_j^0 = c_j^- + c_j^+, \quad a_j = (\bar{r}_j/\bar{p}_j)^{1/2} \epsilon^{-1},
\]

\[
\bar{p}_j = (p(x_{j-1}) + p(x_j))/2, \quad \bar{r}_j = (r(x_{j-1}) + r(x_j))/2,
\]

and

\[
\sigma (x) = x / \sinh (x), \quad \eta (x) = x \coth (x).
\]

Example 7.1. We applied this difference scheme to problem (1.1), with

\[
p(x) = 1 + x^2, \quad r(x) = \cos (x)(3 - x)^{-3},
\]

\[
f(x) = 4(3x^2 - 3x + 1)((x - 0.5)^2 + 2), \quad y(0) = -1, \quad y(1) = 0
\]

(see [2, p. 231]). The results are given in Table 1. The errors (EMAX) and the rates of convergence (RATE) are based on the double mesh principle (see [2, p. 223]). We define, for \( N = 8, 16, \ldots, 512 \),

\[
\text{EMAX} = \max_{0 < j < N} \left| u_j^N - u_{2j}^N \right| \quad \text{and} \quad \text{RATE} = \frac{\ln (E^1) - \ln (E^2))}{\ln(2)}
\]

where \( E^1 \) and \( E^2 \) correspond to EMAX for \( h = 1/N \) and \( h = 1/2N \), respectively.

Example 7.2. We also applied this difference scheme to problem (1.1), with

\[
p(x) = 1, \quad r(x) = \{4 + 4\epsilon (1 + x)\}/(1 + x)^4,
\]

\[
f(x) = \left\{-4/(1 + x)^4\right\}\left\{(1 + \epsilon (1 + x) + 4\pi^2 \epsilon^2 \cos (2\pi x)/2 - 2\epsilon^2 (1 + x) \sin (2\pi x) + 3(1 + \epsilon (1 + x)) \epsilon^{-1/\epsilon} (1 - \epsilon^{-1/\epsilon})^{-1}\right\},
\]

\[
y(0) = 2.0, \quad y(1) = -1.0
\]
(see [10, p. 81]). The results are given in Table 2. In this example, the analytic solution can be computed. Thus we define

\[ E\text{MAX} = \max_{0 < j < N} |y(x_j) - u(x_j)| \quad \text{and} \quad \text{RATE} = \left( \frac{\ln(E^1) - \ln(E^2)}{\ln(2)} \right), \]

where \( E^1 \) and \( E^2 \) correspond to \( E\text{MAX} \) for \( h = 1/N \) and \( h = 1/2N \), respectively.
