ON THE PERIODS OF GENERALIZED FIBONACCI RECURRENCES

RICHARD P. BRENT

Abstract. We give a simple condition for a linear recurrence (mod $2^w$) of degree $r$ to have the maximal possible period $2^{w-1}(2^r - 1)$. It follows that the period is maximal in the cases of interest for pseudorandom number generation, i.e., for three-term linear recurrences defined by trinomials which are primitive (mod 2) and of degree $r > 2$. We consider the enumeration of certain exceptional polynomials which do not give maximal period, and list all such polynomials of degree less than 15.

1. Introduction

The Fibonacci numbers satisfy a linear recurrence

$$F_n = F_{n-1} + F_{n-2}.$$  

Generalized Fibonacci recurrences of the form

$$(1) \quad x_n = \pm x_{n-s} \pm x_{n-r} \mod 2^w$$

are of interest because they are often used to generate pseudorandom numbers [1, 6, 7, 12, 14, 18]. We assume throughout that $x_0, \ldots, x_{r-1}$ are given and not all even, and $w > 0$ is a fixed exponent. Usually, $w$ is close to the wordlength of the (binary) computer used.

Apart from computational convenience, there is no reason to restrict attention to three-term recurrences of the special form (1). Thus, we consider a general linear recurrence

$$(2) \quad q_0 x_n + q_1 x_{n+1} + \cdots + q_r x_{n+r} = 0 \mod 2^w$$

defined by a polynomial $Q(t) = q_0 + q_1 t + \cdots + q_r t^r$ with integer coefficients and degree $r > 0$. We assume throughout that $q_0$ and $q_r$ are odd. Because $q_0$ is odd, the sequence $(x_n)$ is reversible, i.e., $x_n$ is uniquely defined (mod $2^w$) by $x_{n+1}, \ldots, x_{n+r}$. Thus, $(x_n)$ is purely periodic [20].
In the following we often work in a ring \( \mathbb{Z}_m[t]/Q(t) \) of polynomials (mod \( Q \)) whose coefficients are regarded as elements of \( \mathbb{Z}_m \), the ring of integers mod \( m \). For relations \( A = B \) in \( \mathbb{Z}_m[t]/Q(t) \) we use the notation

\[
A = B \mod (m, Q).
\]

It may be shown by induction on \( n \) that, if \( a_{n,0}, \ldots, a_{n,r-1} \) are defined by

\[
t^n = \sum_{j=0}^{r-1} a_{n,j} t^j \mod (2^w, Q(t)),
\]

then

\[
x_n = \sum_{j=0}^{r-1} a_{n,j} x_j \mod 2^w.
\]

Also, the generating function

\[
G(t) = \sum_{n=0}^\infty x_n t^n
\]

is given by

\[
G(t) = \frac{P(t)}{Q(t)} \mod 2^w,
\]

where

\[
P(t) = \sum_{k=0}^{r-1} \left( \sum_{j=0}^{k} q_{r+j-k} x_j \right) t^k
\]

is a polynomial of degree less than \( r \), and

\[
\tilde{Q}(t) = t^r Q(1/t) = q_0 t^r + q_1 t^{r-1} + \cdots + q_r
\]

is the reverse of \( Q \). In the literature, \( \tilde{Q}(t) \) is sometimes called the characteristic polynomial [5] or the associated polynomial [22] of the sequence. The use of generating functions is convenient and has been adopted by many earlier authors (e.g., Schur [16]). Ward [22] does not explicitly use generating functions, but his polynomial \( U \) is the same as our \( \tilde{Q} \), and many of his results could be obtained via generating functions.

Let \( \rho_w \) be the period of \( t \) under multiplication mod \( (2^w, Q(t)) \), i.e., \( \rho_w \) is the least positive integer \( \rho \) such that

\[
t^\rho = 1 \mod (2^w, Q(t)).
\]

In the literature, \( \rho_w \) is sometimes called the principal period [22] of the linear recurrence, sometimes simply the period [5]. For brevity we define \( \lambda = \rho_1 \).

If \( Q(t) \) is irreducible in \( \mathbb{Z}_2[t] \), then \( Q(t) \) is a factor of \( t^{2^r} - t \) (see, e.g., [19]), so \( \lambda \mid 2^r - 1 \). We say that \( Q(t) \) is primitive (mod 2) if \( \lambda = 2^r - 1 \). Note that primitivity is a stronger condition than irreducibility, i.e., \( Q(t) \) primitive
implies that $Q(t)$ is irreducible\(^1\), but the converse is not generally true unless \(2^r - 1\) is prime. For example, the polynomial \(1 + t + t^2 + t^4 + t^6\) is irreducible, but not primitive, since it has \(\lambda = 21 < 2^6 - 1\). Tables of irreducible and primitive trinomials are available [5, 11, 15, 17, 21, 23, 24, 25].

In the following we usually assume that $Q(t)$ is irreducible. Our assumption that $q_0$ and $q_r$ are odd excludes the trivial case $Q(t) = t$, and implies that $Q(t)$ is irreducible (or primitive) of degree $r$ if and only if the same is true of $Q(t)$.

We are interested in the period $p_w$ of the sequence $(x_n)$, i.e., the minimal positive $p$ such that

\[ x_{n+p} = x_n \]

for all sufficiently large $n$. In fact, because of the reversibility of the sequence, (7) should hold for all $n$. The period is sometimes called the characteristic number of the sequence [20]. In general, the period depends on the initial values $x_0, \ldots, x_{r-1}$, but under our assumptions the period depends only on $Q(t)$, in fact $p_w = p_w$ (see Lemma 2).

It is known [8, 13, 20] that $p_w \leq 2^w - 1$, with equality holding for all $w > 0$ if and only if it holds for $w = 3$. The main aim of this paper is to give a simple necessary and sufficient condition for

\[ P_w = 2^w - 1. \]

The result is stated in Theorem 2 in terms of a simple condition which we call “Condition S” (see §2). In Theorem 3 we deduce that the period is maximal if $Q(t)$ is a primitive trinomial of degree greater than 2. Thus, in cases of practical interest for pseudorandom number generation, it is only necessary to verify that $Q(t)$ is primitive. This is particularly easy if $2^r - 1$ is a Mersenne prime, because then a necessary and sufficient condition is

\[ t^{2^r} = t \mod (2, Q(t)). \]

A word of caution is appropriate. Even when the period $p_w$ satisfies (8), it is not desirable to use a full cycle of $p_w$ numbers in applications requiring independent pseudorandom numbers. This is because only the most significant bit has the full period. If the bits are numbered from 1 (least significant) to $w$ (most significant), then bit $k$ has period $p_k$.

The basic results on linear recurrences modulo $m$ were obtained many years ago—see, for example, Ward [20]. However, our main results (Theorems 2 and 3) and the statement of “Condition S” (§2) appear to be new.

2. A Condition for maximal period

The following lemma is a special case of Hensel's Lemma [8, 9, 22] and may be proved using an application of Newton's method for reciprocals [10].

**Lemma 1.** Suppose that $P(t) \mod 2$ is invertible in $\mathbb{Z}_2[t]/Q(t)$. Then, for all $w \geq 1$, $P(t) \mod 2^w$ is invertible in $\mathbb{Z}_{2^w}[t]/Q(t)$.

\(^1\)For brevity we usually omit the “mod 2” when saying that a polynomial is irreducible or primitive. Thus “$Q(t)$ is irreducible (resp. primitive)” means that $Q(t) \mod 2$ is irreducible (resp. primitive) in $\mathbb{Z}_2[t]$. License or copyright restrictions may apply to redistribution; see http://www.ams.org/journal-terms-of-use
We now give a sufficient condition for the periods $p_w$ and $\rho_w$ to be the same.

**Lemma 2.** If $Q(t)$ is irreducible of degree $r$, and at least one of $x_0$, \ldots, $x_{r-1}$ is odd, then $p_w = \rho_w$.

**Proof.** For brevity we write $p = p_w$ and $\rho = \rho_w$. From (5),

$$G(t) = \frac{R(t)}{1 - tp} \mod 2^w,$$

where $R(t)$ has degree less than $p$. Thus, from (6),

$$R(t)Q(t) = (1 - tp)P(t) \mod 2^w.$$  

$P(t) \mod 2$ has degree less than $r$, but is not identically zero. Since $\tilde{Q}(t) \mod 2$ is irreducible of degree $r$, application of the extended Euclidean algorithm [8] to $P(t) \mod 2$ and $\tilde{Q}(t) \mod 2$ constructs the inverse of $P(t) \mod 2$ in $\mathbb{Z}_2[t]/\tilde{Q}(t)$. Thus, Lemma 1 shows that $P(t) \mod 2^w$ is invertible in $\mathbb{Z}_2^w[t]/\tilde{Q}(t)$. It follows from (9) that

$$t^p = 1 \mod (2^w, \tilde{Q}(t)),$$

and $\rho \mid p$. However, from (3) and (4), $p \mid \rho$. Thus, $p = \rho$. □

As an example, consider $Q(t) = 1 - t + t^2$. We have $t^3 = 1 \mod (2, Q(t))$, $t^3 = -1 \mod Q(t)$, and $t^6 = 1 \mod Q(t)$, so

$$\rho_w = \begin{cases} 3 & \text{if } w = 1, \\ 6 & \text{if } w > 1. \end{cases}$$

It is easy to verify that (10) gives the period $p_w$ of the corresponding recurrence

$$x_n = x_{n-1} - x_{n-2} \mod 2^w,$$

provided $x_0$ and $x_1$ are not both even.

The assumption of irreducibility in Lemma 2 is significant. For example, consider $Q(t) = t^2 - 1$ and $w = 1$, with initial values $x_0 = x_1 = 1$. The recurrence is $x_n = x_{n-2} \mod 2$, so $p_1 = 1$, but $\rho_1 = 2$. Here, $P(t) = 1 + t$ is a divisor of $\tilde{Q}(t) = 1 - t^2$.

We now define a condition which must be satisfied by $Q(\pm t)$ if the period $p_w$ of the sequence $(x_n)$ is less than $2^{w-1}\lambda$ (see Theorem 2 for details). For given $Q(t)$ the condition can be checked in $O(r^2)$ operations, or in $O(r \log r)$ operations if the FFT is used to compute the convolutions in (11). Even the $O(r^2)$ algorithm is much faster than the method suggested by Marsaglia and Tsay [13], which involves forming high powers of $r \times r$ matrices (mod 8), or the method of Knuth [8, ex. 3.2.2.11], which involves forming high powers in $\mathbb{Z}_8[t]/Q(t)$.

**Condition S.** Let $Q(t) = \sum_{j=0}^{r} q_j t^j$ be a polynomial of degree $r$. We say that $Q(t)$ satisfies Condition S if and only if

$$Q(t)^2 + Q(-t)^2 = 2q_r Q(t^2) \mod 8.$$
Lemma 3 gives an equivalent condition, which is more convenient for computational purposes. For another equivalent condition, see the remark following (22) in the proof of Theorem 1. The proof of Lemma 3 is straightforward, so is omitted.

**Lemma 3.** A polynomial \( Q(t) \) of degree \( r \) satisfies Condition S if and only if

\[
\sum_{j+k=2m, 0<j<k<r} q_j q_k = \epsilon_m \mod 2
\]

for \( 0 \leq m \leq r \), where

\[
\epsilon_m = \frac{q_m(q_m - q_r)}{2}.
\]

As an exercise, the reader may verify that the polynomial \( Q(t) = 1 - t + t^2 \) satisfies both the definition of Condition S and the equivalent conditions of Lemma 3. For other examples, see Table 1.

For convenience we collect in Lemma 4 some results regarding arithmetic in the rings \( \mathbb{Z}_{2^w}[t]/Q(t) \).

**Lemma 4.** Let \( X(t) \) and \( Y(t) \) be polynomials over \( \mathbb{Z} \), and \( Q(t) \) be as in §1. Then, for \( w \geq 1 \),

\[
X = Y \mod (2^w, Q) \Rightarrow X^2 = Y^2 \mod (2^{w+1}, Q).
\]

Also, if \( Q(t) \) is irreducible, then

\[
X^2 = Y^2 \mod (2, Q) \iff X^2 = Y^2 \mod (4, Q)
\]

and

\[
X^2 = Y^2 \mod (8, Q) \iff X = \pm Y \mod (4, Q).
\]

**Proof.** If \( X = Y \mod (2^w, Q) \), then \( X = Y + 2^w R \mod Q \) for some polynomial \( R(t) \) in \( \mathbb{Z}[t] \). Thus, \( X^2 = Y^2 + 2^{w+1} R(Y + 2^{w-1} R) \mod Q \), and (13) follows.

If \( Q(t) \) is irreducible and \( X^2 = Y^2 \mod (2, Q) \), then \( (X - Y)^2 = 0 \mod (2, Q) \). Since \( Q \) is irreducible, it follows that \( X = Y \mod (2, Q) \). Thus, from (13), \( X^2 = Y^2 \mod (4, Q) \), and (14) follows.

Finally, if \( Q \) is irreducible and \( X^2 = Y^2 \mod (8, Q) \) then, as in the proof of (14), we obtain \( X = Y \mod (2, Q) \), so \( X = Y + 2R \mod Q \), where \( R(t) \) is some polynomial in \( \mathbb{Z}[t] \). Thus, \( 4R(Y + R) = 0 \mod (8, Q) \), i.e., \( R(Y + R) = 0 \mod (2, Q) \). Since \( Q \) is irreducible, either \( R = 0 \mod (2, Q) \) or \( Y + R = 0 \mod (2, Q) \). In the former case, \( X = Y \mod (4, Q) \), and in the latter case, \( X = -Y \mod (4, Q) \). Thus, \( X = \pm Y \mod (4, Q) \). The implication in the other direction follows from (13). This establishes (15). \( \square \)

The following result is the key to the proof of Theorem 2. There is no obvious generalization to odd moduli. Recall that \( \lambda = \rho_1 \).
Theorem 1. Let \( Q(t) \mod 2 \) be irreducible in \( \mathbb{Z}_2[t] \). Then
\[
t^2 = -1 \mod (4, Q(t))
\]
if and only if \( Q(t) \) satisfies Condition S, and
\[
t^2 = 1 \mod (4, Q(t))
\]
if and only if \( Q(-t) \) satisfies Condition S.

Proof. Let
\[
V(t) = \sum_{j=0}^{[r/2]} q_{2j}t^j, \quad W(t) = \sum_{j=0}^{[(r-1)/2]} q_{2j+1}t^j,
\]
so \( Q(t) \) splits into even and odd parts:
\begin{equation}
Q(t) = V(t^2) + tW(t^2).
\end{equation}
By the definition of \( \lambda \), we have \( t = t^{\lambda+1} \mod (2, Q(t)) \), so
\begin{equation}
V(t^2) = t^{\lambda+1}W(t^2) \mod (2, Q(t)).
\end{equation}
Because \( X(t^2) = X(t)^2 \mod 2 \) for any polynomial \( X(t) \) in \( \mathbb{Z}[t] \), equation (17) may be written as
\[V(t)^2 = t^{\lambda+1}W(t)^2 \mod (2, Q(t)).\]
Since \( \lambda \) is a divisor of \( 2^r - 1 \), it is odd, so \( t^{\lambda+1} \) is a square. Thus, from (14),
\begin{equation}
V(t)^2 = t^{\lambda+1}W(t)^2 \mod (4, Q(t)).
\end{equation}
Also, since \( V(t) = V(-t) \mod 2 \) and \( W(t) = W(-t) \mod 2 \), we have
\begin{equation}
V(-t)^2 = t^{\lambda+1}W(-t)^2 \mod (4, Q(t)).
\end{equation}
To prove the first half of the theorem, suppose that
\[t^2 = -1 \mod (4, Q(t)).\]
Thus, from (18),
\begin{equation}
V(t)^2 + tW(t)^2 = 0 \mod (4, Q(t)).
\end{equation}
It follows that
\begin{equation}
V(t)^2 + tW(t)^2 - q_rQ(t) = 0 \mod (4, Q).
\end{equation}
However, the left side of (21) is a polynomial of degree less than \( r \). Hence,
\begin{equation}
V(t)^2 + tW(t)^2 - q_rQ(t) = 0 \mod 4.
\end{equation}
Replace \( t \) by \( t^2 \) in the identity (22). From (16), the result is easily seen to be equivalent to \( Q(t) \) satisfying Condition S.
To prove the converse, suppose that \( Q(t) \) satisfies Condition S. Reversing our argument, we see that (20) holds. Thus, from (18),

\[
(t^{k+1} + t)W(t)^2 = 0 \mod (4, Q(t)).
\]

Now \( W(t) \) has degree less than \( r \), and \( W(t) \not\equiv 0 \mod 2 \), because otherwise, using (16), \( Q(t) = V(t)^2 \mod 2 \) would contradict the irreducibility of \( Q(t) \). It follows that \( W(t) \mod 2 \) is invertible in \( \mathbb{Z}_2[t]/Q(t) \). From Lemma 1, \( W(t) \mod 4 \) is invertible in \( \mathbb{Z}_4[t]/Q(t) \), and we obtain

\[
t^{k+1} + t = 0 \mod (4, Q(t)).
\]

Since \( Q(t) \not\equiv t \mod 2 \), we can divide by \( t \) to obtain

\[
t^k = -1 \mod (4, Q(t)).
\]

This completes the proof of the first half of the theorem.

The proof of the second half is similar, with appropriate changes of sign. Suppose that

(23) \[
t^k = 1 \mod (4, Q(t)).
\]

From (19),

\[
V(-t)^2 = tW(-t)^2 \mod (4, Q(t)).
\]

Thus, instead of (22) we obtain

(24) \[
V(-t)^2 - tW(-t)^2 - (-1)^r q_r Q(t) = 0 \mod 4.
\]

Replace \( t \) by \( -t^2 \) in the identity (24). The result is equivalent to \( Q(-t) \) satisfying Condition S. The converse also applies: if \( Q(-t) \) satisfies Condition S then, by reversing our argument and using irreducibility of \( Q(t) \), we find that (23) holds. \( \square \)

We are now ready to state Theorem 2, which relates the period of the sequence \( (x_n) \) to Condition S. In view of Theorem 1, Theorem 2 is implicit in Ward [20, p. 628]. More precisely, Ward’s case \( T > 1 \) corresponds to \( Q(-t) \) satisfying Condition S, while Ward’s case (\( T = 1, K(x) = 1 \mod 2 \)) corresponds to \( Q(t) \) satisfying Condition S. However, Ward’s exposition is complicated by consideration of odd prime power moduli (see for example his Theorem 13.1), so we give an independent proof.

**Theorem 2.** Let \( Q(t) \) be irreducible and define a linear recurrence by (2), with at least one of \( x_0, \ldots , x_{r-1} \) odd. Then the sequence \( (x_n) \) has period

\[
p_w \leq 2^{w-2} \lambda
\]

for all \( w \geq 2 \) if \( Q(-t) \) satisfies Condition S, and

\[
p_w \leq 2^{w-2} \lambda
\]

for all \( w \geq 3 \) if \( Q(t) \) satisfies Condition S, and

\[
p_w = 2^{w-1} \lambda
\]

for all \( w \geq 1 \) if and only if neither \( Q(t) \) nor \( Q(-t) \) satisfies Condition S.
Proof. From Lemma 2, $p_w = p_w$ is the order of $t \mod (2^w, Q(t))$. If $Q(-t)$ satisfies Condition S, then, from Theorem 1,

$$t^l = 1 \mod (4, Q(t)).$$

By (13), it follows by induction on $w$ that

$$t^{2w-2l} = 1 \mod (2^w, Q(t))$$

for all $w \geq 2$. This proves the first part of the theorem. The second part is similar, so it only remains to prove the third part.

Suppose that $p_w = 2^{w-1}l$ for all $w > 0$. In particular, for $w = 3$ we have period $p_3 = 4l$. Thus,

$$t^{2l} \neq 1 \mod (8, Q(t))$$

and, from (15),

$$t^l \neq \pm 1 \mod (4, Q(t)).$$

From Theorem 1, neither $Q(t)$ nor $Q(-t)$ can satisfy Condition S, or we would obtain a contradiction to (25).

Conversely, if neither $Q(t)$ nor $Q(-t)$ satisfies Condition S, then we show by induction on $w$ that

$$t^{2w-1l} = 1 + 2^w R_w \mod Q(t),$$

where

$$R_w \neq 0 \mod (2, Q(t)),$$

for all $w \geq 1$. Certainly,

$$t^l = 1 \mod (2, Q(t)),$$

but, from Theorem 1,

$$t^l \neq 1 \mod (4, Q(t)),$$

so (26) and (27) hold for $w = 1$. Defining

$$R_w = R_{w-1}(1 + 2^{w-2}R_{w-1})$$

for $w \geq 2$, we see that (26) holds for all $w \geq 1$. It remains to prove (27) for $w > 1$.

For $w = 2$, inequality (27) follows from Theorem 1 and (15), as $t^l \neq \pm 1 \mod (4, Q(t))$ implies $t^{2l} \neq 1 \mod (8, Q(t))$. For $w > 2$, the inequality (27) follows by induction from (28), since $2^{w-2}$ is even. It follows that $p_w = 2^{w-1}l$ for all $w \geq 1$. □

3. Primitive trinomials

In this section we consider a case of interest because of its applications to pseudorandom number generation:

$$Q(t) = q_0 + q_s t^s + q_r t^r$$

is a trinomial ($r > s > 0$). Theorem 3 shows that the period is always maximal in cases of practical interest. The condition $r > 2$ is necessary, as the example $Q(t) = 1 - t + t^2$ of §2 shows.
Theorem 3. Let \( Q(t) = q_0 + q_s t^s + q_r t^r \) be a primitive trinomial of degree \( r > 2 \). Then the sequence \( (x_n) \) defined by (2), with at least one of \( x_0, \ldots, x_{r-1} \) odd, has period \( p_w = 2^{w-1}(2^r - 1) \).

Proof. From Theorem 2 it is sufficient to show that \( Q(t) \) does not satisfy Condition S. (Since \( Q(-t) \) is also a trinomial, the same argument shows that \( Q(-t) \) does not satisfy Condition S.)

Suppose, by way of contradiction, that \( Q(t) \) satisfies Condition S. We use the formulation of Condition S given in Lemma 3. Since \( Q(t) \) is irreducible, we have \( q_0 = q_s = q_r = 1 \mod 2 \). If \( s \) is even, say \( s = 2m \), then

\[
\sum_{0 \leq j < k \leq r} q_j q_k = q_0 q_3 = 1 \mod 2,
\]

so \( \epsilon_m \neq 0 \), and (12) implies that \( q_m \neq 0 \). Since \( 0 < m < s < r \), this contradicts the assumption that \( Q(t) \) is a trinomial. Hence, \( s \) must be odd.

If \( r \) is odd then \( r+s \) is even, and a similar argument shows that \( q_{(r+s)/2} \neq 0 \), contradicting the assumption that \( Q(t) \) is a trinomial. Hence, \( r \) must be even.

Taking \( m = r/2 \), we see that \( \epsilon_m \neq 0 \), so \( q_m \neq 0 \). This is only possible if \( m = s \), so \( Q(t) = t^{2s} + t^s + 1 \mod 2 \). In this case, \( t^{3s} = 1 \mod (2, Q(t)) \). Now \( r = 2s > 2 \), so \( 3s < 2^r - 1 \), and \( Q(t) \) cannot be primitive. This contradiction completes the proof. \( \square \)

A minor modification of the proof of Theorem 3 gives:

Theorem 4. Let \( Q(t) = q_0 + q_s t^s + q_r t^r \) be an irreducible trinomial of degree \( r \neq 2s \). Then the sequence \( (x_n) \) defined by (2), with at least one of \( x_0, \ldots, x_{r-1} \) odd, has period \( p_w = 2^{w-1} \).

As mentioned above, it is easy to find primitive trinomials of very high degree \( r \) if \( 2^r - 1 \) is a Mersenne prime. Zierler [24] gives examples with \( r \leq 9689 \), and we found two examples with higher degree: \( t^{9937} + t^{9842} + 1 \) and \( t^{23209} + t^{9739} + 1 \). These and other examples with \( r \leq 44497 \) were found independently by Kurita and Matsumoto [11]. Such primitive trinomials provide the basis for fast random number generators with extremely long periods and good statistical properties [3]. In general, random number generators with larger \( r \) have better statistical properties than those with smaller \( r \), and generators with small \( r \) should be avoided [3, 4].

4. Exceptional polynomials

We say that a polynomial \( Q(t) \) of degree \( r > 1 \) is exceptional if conditions E1–E3 hold, and is a candidate if conditions E2–E3 hold:

- E1. \( Q(t) \mod 2 \) is primitive.
- E2. \( Q(t) \) has coefficients \( q_j \in \{0, -1, +1\} \) and \( q_0 = q_r = 1 \).
- E3. \( Q(t) \) satisfies Condition S.

If \( Q(t) \) is exceptional then, by Theorem 2, \( Q(t) \) and \( Q(-t) \) define linear recurrences (mod \( 2^w \)) which have less than the maximal period for all \( w > 2 \). In Table 1 we list the exceptional polynomials \( Q(t) \) of degree \( r \leq 14 \). If \( Q(t) \) is exceptional, then so is \( Q(-t) \). Thus, we only list one of these in Table 1.
Table 1. Exceptional polynomials of degree $r \leq 14$

Only the coefficients of $Q(t) \mod 4$ are relevant to Condition S. If condition E2 is relaxed to allow coefficients equal to 2, then, by Lemma 3, there is one such $Q(t)$ corresponding to each primitive polynomial in $\mathbb{Z}_2[t]$. With condition E2 as stated, the number of these $Q(t)$ is considerably reduced.

It is interesting to consider strengthening condition E2 by asking for certain patterns in the signs of the coefficients. For example, we might ask for polynomials $Q(t)$ with all coefficients $q_j \in \{0, 1\}$, or for all coefficients of $\pm Q(-t)$ to be in $\{0, 1\}$. There are candidates satisfying these conditions, but we have not found any which are also exceptional, apart from the trivial $Q(t) = 1 - t + t^2$.

It is possible for an exceptional polynomial to have $(-1)^j q_j \geq 0$ for $0 \leq j < r$. The only example for $2 < r \leq 44$ is

$$Q(t) = 1 - t + t^2 - t^5 + t^6 + t^8 - t^9 + t^{10} + t^{12} - t^{13} + t^{16} + t^{18} + t^{21}.$$ 

Observe that $Q(-t)$ defines a linear recurrence with nonnegative coefficients

$$x_{n+21} = x_n + x_{n+1} + x_{n+2} + x_{n+5} + x_{n+6} + x_{n+8}$$
$$+ x_{n+9} + x_{n+10} + x_{n+12} + x_{n+13} + x_{n+16} + x_{n+18},$$

which has period $p_2 = p_1 = 2^{21} - 1$ when considered mod 2 or mod 4.

The number $\nu(r)$ of exceptional $Q(t)$ (counting only one of $Q(t)$, $\overline{Q}(t)$) is given in Table 2. The term “exceptional” is justified as $\nu(r)$ appears to be a much more slowly growing function of $r$ than the number $[5]$

$$\lambda_2(r) = \varphi(2^r - 1)/r$$

</table>

of primitive polynomials of degree \(r\) in \(\mathbb{Z}_2[t]\) (where \(\phi\) is Euler's totient function) or the total number of polynomials of degree \(r\) with coefficients in \(\{0, -1, +1\}\). A heuristic argument suggests that the number \(\kappa(r)\) of candidates should grow like \((3/2)^r\) and that \(\nu(r)\) should grow like \((3/4)^r\lambda_2(r)\). The argument is as follows:

There are \(2^{r-1}\) polynomials \(\overline{Q}(t)\) of degree \(r\) with coefficients in \(\{0, 1\}\), satisfying \(q_0 = q_r = 1\). Randomly select such a \(\overline{Q}(t)\), and compute \(\epsilon_0, \epsilon_1, \ldots, \epsilon_r\) from

\[
\sum_{j+k=2m \atop 0 \leq j < k \leq r} q_j q_k = \epsilon_m \mod 2.
\]

Extend \(\overline{Q}(t)\) to a polynomial \(Q(t)\) with coefficients \(q_m \in \{-1, 0, 1, 2\}\) such that \(q_m = q_m \mod 2\) and (12) is satisfied for \(0 \leq m \leq r\). The (unique) mapping is given by \(q_m = \overline{q}_m + 2\epsilon_m \mod 4\). It is easy to see that \(q_0 = q_r = 1\). If we assume that, for \(1 \leq m < r\), each \(q_m\) has independent probability \(1/4\) of assuming the “forbidden” value \(2\), then the probability that \(Q(t)\) is a candidate is \((3/4)^{r-1}\). Thus,

\[
\kappa(r) \approx (3/2)^{r-1}.
\]

The probability that a randomly chosen \(\overline{Q}(t)\) with \(q_0 = q_r = 1\) is primitive is just \(\lambda_2(r)/2^{r-1}\). If there is the same probability that a randomly chosen candidate is primitive, then the number of primitive candidates should be \((3/4)^{r-1}\lambda_2(r)\), and \(\nu(r)\) should be half this number.

The argument is not strictly correct. For example, it gives a positive probability that \(q_1 = 0, q_2 = 1\), but this never occurs for \(r > 2\). However, the argument does appear to predict the correct order of magnitude of \(\kappa(r)\) and \(\nu(r)\). In Table 2 we give

\[
\overline{\nu}(r) = \frac{\nu(r)}{(3/4)^r\lambda_2(r)};
\]

the numerical evidence suggests that \(\overline{\nu}(r)\) converges to a positive constant \(\overline{\nu}(\infty)\) as \(r \to \infty\). However, \(\overline{\nu}(\infty)\) is less than the value \(2/3\) predicted by the heuristic argument. Our best estimate (obtained from a separate computation which
gives faster convergence) is

\[ \overline{v}(\infty) = 0.45882 \pm 0.00002. \]

The computation of Table 2 took 166 hours on a VaxStation 3100. We outline the method used. It is easy to check if a candidate polynomial is exceptional [8]. A straightforward method of enumerating all candidate polynomials of degree \( r \) is to associate a polynomial \( Q(t) \) such that \( q_0 = q_r = 1 \) with an \( (r - 1) \)-bit binary number \( N = b_1 \cdots b_{r-1} \), where \( b_j = q_j \mod 2 \). For each such \( N \), compute \( \epsilon_0, \ldots, \epsilon_r \) from (11). Now (12) defines \( q_0, \ldots, q_r \mod 4 \). If there is an index \( m \) such that \( \epsilon_m = 1 \mod 2 \) but \( q_m = 0 \mod 2 \), then (12) shows that \( q_m = 2 \mod 4 \), contradicting condition E2. The straightforward enumeration has complexity \( \Omega(2^r) \), but this can be reduced by two devices:

A. If (12) shows that \( q_m = 2 \mod 4 \) for some \( m < r/2 \), we may use the fact that \( \epsilon_m \) in (11) depends only on \( q_0, \ldots, q_{2m} \) to skip over a block of \( 2^{r-2m-1} \) numbers \( N \). By an argument similar to the heuristic argument for the order of magnitude of \( \nu(r) \), with support from empirical evidence for \( r \leq 40 \), we conjecture that this device reduces the complexity of the enumeration to

\[ O(r^2 2^r (3/4)^{r/2}) = O(r^{2r^{3/4}/2}). \]

B. Fix \( s \), \( 0 < s < r \). Since \( \epsilon_{r-m} \) in (11) depends only on \( q_{r-2m}, \ldots, q_r \), we can tabulate those low-order bits \( b_{r-s} \cdots b_{r-1} \) which do not necessarily lead to condition E2 being violated for some \( q_{r-m}, 2m \leq s \). In the enumeration we need only consider \( N \) with low-order bits in the table. We conjecture that this reduces the complexity of the enumeration to

\[ O(r^2 2^r (3/4)^{s/2}) = O(r^2 2^r s^s/2), \]

provided care is taken to generate the table efficiently.

The two devices can be combined, but they are not independent. The complexity of the combination is conjectured to be

\[ O(r^2 2^r (3/4)^{(6s+5s)/12}) = O(r^2 3^{r/2}(3/4)^{5s/12}), \]

where the exponent \( 5s/12 \) (instead of \( s/2 \)) reflects the lack of independence. In the computation of Table 2 we used \( s \leq 22 \) because of memory constraints. The table size is \( O(s^{3s/2}) \) bits, if the table is stored as a list to take advantage of sparsity.

Note added in proof. Examples of primitive trinomials with \( r \leq 132049 \) were recently found by Heringa, Blöte and Compagner, Internat. J. Modern Phys. C 3 (1992), 561–564.

Acknowledgments

We thank a referee for pointing out an error in the formulation of Lemma 2 given in [2], and for providing references to the classical literature. Richard Walker's assistance with \( \LaTeX \) was invaluable. The ANU Supercomputer Facility provided time on a Fujitsu VP 2200/10 for the discovery of the primitive trinomials mentioned at the end of §3.
