A CONVERGENCE AND STABILITY STUDY
OF THE ITERATED LUBKIN TRANSFORMATION
AND THE $\theta$-ALGORITHM

AVRAM SIDI

ABSTRACT. In this paper we analyze the convergence and stability of the iterated Lubkin transformation and the $\theta$-algorithm as these are being applied to sequences $\{A_n\}$ whose members behave like $A_n \sim A + \zeta^n/(n!)^r \sum_{i=0}^{\infty} \alpha_i n^{\gamma-i}$ as $n \to \infty$, where $\zeta$ and $\gamma$ are complex scalars and $r$ is a nonnegative integer. We study the three different cases in which (i) $r = 0$, $\zeta = 1$, and $\gamma \neq 0, 1, \ldots$ (logarithmic sequences), (ii) $r = 0$ and $\zeta \neq 1$ (linear sequences), and (iii) $r = 1, 2, \ldots$ (factorial sequences). We show that both methods accelerate the convergence of all three types of sequences. We show also that both methods are stable on linear and factorial sequences, and they are unstable on logarithmic sequences. On the basis of this analysis we propose ways of improving accuracy and stability in problematic cases. Finally, we provide a comparison of these results with analogous results corresponding to the Levin $u$-transformation.

1. INTRODUCTION AND BACKGROUND

The purpose of this work is to contribute to our understanding of how the iterated $W$-transformation of Lubkin \cite{7} and the $\theta$-algorithm of Brezinski \cite{2} accelerate the convergence of some important classes of infinite sequences $\{A_n\}$. The sequences that we have in mind are the following:

1. Logarithmic sequences for which

$$A_n \sim A + \sum_{i=0}^{\infty} \alpha_i n^{\gamma-i} \text{ as } n \to \infty; \quad \alpha_0 \neq 0, \, \gamma \neq 0, 1, 2, \ldots.$$  \hspace{1cm} (1.1)

Here $A = \lim_{n \to \infty} A_n$ when $\Re \gamma < 0$. When $\Re \gamma \geq 0$, $A$ is the antilimit of $\{A_n\}$.

2. Linear sequences for which

$$A_n \sim A + \zeta^n \sum_{i=0}^{\infty} \alpha_i n^{\gamma-i} \text{ as } n \to \infty; \quad \alpha_0 \neq 0, \, \zeta \neq 1.$$  \hspace{1cm} (1.2)

Here $A = \lim_{n \to \infty} A_n$ when (a) $|\zeta| < 1$ or (b) $|\zeta| = 1$ and $\Re \gamma < 0$. Otherwise, $A$ is the antilimit of $\{A_n\}$.

3. Factorial sequences for which

\[ A_n \sim A + \frac{\zeta^n}{(n!)^r} \sum_{i=0}^{\infty} \alpha_i n^{\gamma - i} \quad \text{as } n \to \infty; \quad \alpha_0 \neq 0, \ r = 1, 2, \ldots. \]

Here \( A = \lim_{n \to \infty} A_n \) always.

Of these, the classes of logarithmic and linear sequences have provided researchers with important test grounds for the comparative study of convergence acceleration methods, including the Shanks transformation [9] (or the equivalent \( \varepsilon \)-algorithm of Wynn [13]), the \( \theta \)-algorithm, the iterated \( W \)-transformation, the Levin [5] transformations, and so on. See, e.g., Smith and Ford [15], [16] and Van Tuyl [17].

If we let \( a_0 = A_0 \) and \( a_n = \Delta A_{n-1} = A_n - A_{n-1}, \ n = 1, 2, \ldots \), then we realize that the \( a_n \) grow as

\[ a_n \sim \sum_{i=0}^{\infty} e_i n^{\gamma - i} \quad \text{as } n \to \infty; \quad e_0 = \gamma \alpha_0 \neq 0, \ \gamma \neq 0, 1, \ldots \quad \text{(for (1.1))}, \]

\[ a_n \sim \zeta^n \sum_{i=0}^{\infty} e_i n^{\gamma - i} \quad \text{as } n \to \infty; \quad e_0 = (1 - \zeta^{-1}) \alpha_0 \neq 0, \ \zeta \neq 1 \quad \text{(for (1.2))}, \]

\[ a_n \sim \frac{\zeta^n}{(n!)^r} \sum_{i=0}^{\infty} e_i n^{\gamma + r - i} \quad \text{as } n \to \infty; \quad e_0 = -\zeta^{-1} \alpha_0 \neq 0, \ r = 1, 2, \ldots \quad \text{(for (1.3))}. \]

(Of course, the \( e_i \) are different in each of (1.4)–(1.6).) Furthermore, the \( a_n \) satisfy 2-term recursion relations of the form

\[ a_{n+1} = c(n) a_n, \]

where \( c(n) \) satisfies asymptotically

\[ c(n) \sim 1 + (\gamma - 1)n^{-1} + c_2 n^{-2} + \cdots \quad \text{as } n \to \infty; \quad \gamma \neq 0, 1, 2, \ldots \quad \text{(in (1.1))}, \]

\[ c(n) \sim \zeta \left( 1 + \gamma n^{-1} + c_2 n^{-2} + \cdots \right) \quad \text{as } n \to \infty; \quad \zeta \neq 1 \quad \text{(in (1.2))}, \]

\[ c(n) \sim \zeta n^{-r} \left( 1 + \gamma n^{-1} + c_2 n^{-2} + \cdots \right) \quad \text{as } n \to \infty; \quad r = 1, 2, \ldots \quad \text{(in (1.3))}. \]

Conversely, if the \( a_n \) satisfy (1.7) with (1.8) or (1.9) or (1.10), then they have asymptotic expansions that are given exactly as in (1.4) or (1.5) or (1.6), respectively. This has been shown in Ford [14, p. 70].

Conversely again, if \( a_n \) are as in (1.4) or (1.5) or (1.6) and \( A_n = \sum_{k=0}^{n} a_k, \ n = 0, 1, \ldots, \) then the \( A_n \) have asymptotic expansions that are given exactly as in
Invoking (1.7), we can write
\[ A_n = A + a_{n+1} \sum_{i=0}^{\infty} \beta_i n^{-i} \text{ as } n \to \infty; \quad \beta_0 = \gamma^{-1} \neq 0 \text{ for } (1.4), \]
\[ A_n \sim A + a_{n+1} \sum_{i=0}^{\infty} \beta_i n^{-i} \text{ as } n \to \infty; \quad \beta_0 = (\zeta - 1)^{-1} \neq 0 \text{ for } (1.5), \]
\[ A_n \sim A + a_{n+1} \left( -1 + \sum_{i=r}^{\infty} \beta_i n^{-i} \right) \text{ as } n \to \infty; \quad \beta_r = -\zeta \neq 0 \text{ for } (1.6). \]

The expansions in (1.11) and (1.12) were given by the author in [10] and [11] for convergent \( \sum_{k=0}^{\infty} a_k \). The result in (1.11) for divergent \( \sum_{k=0}^{\infty} a_k \) was given in [13], where the nature of the antilimit \( A \) and its precise value are also provided. The result in (1.12) for divergent \( \sum_{k=0}^{\infty} a_k \) was given in [12] for the case \( |\zeta| = 1, \zeta \neq 1 \), where it is shown that the antilimit \( A \) is the Abel sum of \( \sum_{k=0}^{\infty} a_k \), namely, \( A = \lim_{\tau \to -1^{+}} \sum_{k=0}^{\infty} a_k \tau^k \). \( A \) is also the analytic continuation to \( |\zeta| = 1 \) of \( f(\zeta) \), the function that is defined by the power series \( \sum_{k=0}^{\infty} c_k \zeta^k \), \( c_n = a_n \zeta^{-n} \), \( n = 0, 1, \ldots \), and that is analytic for \( |\zeta| < 1 \). In [12] it is shown in addition that (1.12) holds also when \( |\zeta| > 1, \zeta \notin [1, +\infty) \), if \( a_n = \zeta^n p h(n) \), where \( p \) is a nonnegative integer and \( h(n) = \int_{0}^{\infty} e^{-nt} \varphi(t) \, dt \), \( \varphi(t) \) being a function of exponential order for which \( a_n \) has an asymptotic expansion of the form given in (1.5). In this case, the antilimit of \( \{A_n\} \), is \( f(\zeta) \), described above, that is now defined and analytic for all \( \zeta \) in the complex plane cut along \([1, +\infty)\).

The result in (1.13) is new and can be proved as follows: Since \( \{A_n\} \) converges when \( a_n \) is as in (1.6), we have \( A_n - A = -\sum_{k=0}^{\infty} a_k \) and \( \sum_{k=0}^{\infty} a_k \) is a convergent series. Invoking (1.7), we can write
\[ A_n - A = -a_{n+1} \left[ 1 + \sum_{k=1}^{\infty} \prod_{j=1}^{k} c(n+j) \right]. \]

By (1.10) the term inside the square brackets has an asymptotic expansion of the form \( 1 + \sum_{i=r}^{\infty} \sigma_i n^{-i} \) as \( n \to \infty \), with \( \sigma_r = \zeta \). This produces (1.13). (We must note, however, that an expansion of the form \( A_n \sim A + a_{n+1} \sum_{i=0}^{\infty} \beta_i n^{-i} \) as \( n \to \infty \) is already contained in the paper [10] for the case in which \( \{A_n\} \) satisfies (1.3).)

The results in (1.11) - (1.13) will be used later in proving theorems on the convergence and convergence acceleration of the (iterated) \( W \)-transformation and the \( \theta \)-algorithm. It must be noted here that the fact that \( \beta_1 = \cdots = \beta_{r-1} = 0 \) in (1.13) is of great importance in the convergence theorems of the next two sections. Without this knowledge one cannot show that there is convergence acceleration, for example.

We now turn to the definitions of the \( W \)- and iterated \( W \)-transformations and the \( \theta \)-algorithm.

Two convenient representations of the \( W \)-transformation on \( \{A_k\} \) are given by
\[ W_j(\{A_k\}) = \frac{\Delta^2(A_j/\Delta A_j)}{\Delta^2(1/\Delta A_j)} = \frac{\Delta(A_{j+1} - \Delta A_j)}{\Delta^2(1/\Delta A_j)}, \quad j = 0, 1, \ldots. \]
This transformation is normally applied in iterated form as in
\begin{equation}
B_0^{(j)} = A_j, \quad j = 0, 1, \ldots, \tag{1.15}
B_{n+1}^{(j)} = W_j(\{ B_n^{(s)} \}), \quad j, n = 0, 1, \ldots, \ldots
\end{equation}

Thus \( B_1^{(j)} = W_j(\{ A_s \}) \). In addition, \( B_n^{(j)} \) is determined from \( A_{j+k}, \quad k = 0, 1, \ldots, 3n \).

The \( \theta \)-algorithm on \( \{ A_k \} \) is defined via the recursion relations
\begin{align}
\theta_1^{(j)} &= 0, \quad \theta_0^{(j)} = A_j, \quad j = 0, 1, \ldots, \tag{1.16}
\theta_{2n+1}^{(j)} &= \theta_{2n-1}^{(j)} + \frac{1}{\Delta \theta_{2n}^{(j)}}, \\
\theta_{2n+2}^{(j)} &= \theta_{2n}^{(j)} + \frac{\Delta \theta_{2n+1}^{(j)} \times \Delta \theta_{2n+1}^{(j)}}{\Delta^2 \theta_{2n+1}^{(j)}}, \quad j, n = 0, 1, \ldots,
\end{align}

where \( \Delta \theta_{2n}^{(j)} = \theta_{2n+1}^{(j)} - \theta_{2n}^{(j)} \) for all \( j \) and \( p \).

Note that \( \theta_{2n}^{(j)} \) is determined from \( A_{j+k}, \quad k = 0, 1, \ldots, 3n \), just like \( B_n^{(j)} \).

Using the fact that \( \theta_{1}^{(j)} = 1/\Delta A_j \) in (1.10), it can be shown after some algebra that
\begin{equation}
\theta_2^{(j)} = W_j(\{ A_s \}). \tag{1.17}
\end{equation}
This fact was first noted by Drummond [3]. Also, from the fact that the Levin \( u \)-transformation on \( \{ A_k \} \) produces the approximations \( u_n^{(j)} \) to \( A \) as in
\begin{equation}
u_n^{(j)} = \frac{\Delta^u (j^{n-2} A_j / \Delta A_j)}{\Delta^u (j^{n-2} / \Delta A_j)}, \tag{1.18}
\end{equation}
see Sidi [10], it is clear that
\begin{equation}
u_2^{(j)} = W_j(\{ A_s \}), \tag{1.19}
\end{equation}
and this was first observed by Bhowmick, Bhattacharya, and Roy [1].

Sablomière [8] and Van Tuyyl [17] have provided the convergence analysis for the sequences \( \{ B_n^{(j)} \}_{j=0}^{\infty} \) as these are obtained from logarithmic sequences \( \{ A_k \} \) in (1.1). In fact, both papers deal with sequences \( \{ A_k \} \) for which \( A_n \sim A + \sum_{i=0}^{\infty} a_i n^{-i/s} \) as \( n \to \infty \), where \( s = 1, 2, \ldots \). In [8] explicit treatment is given for \( s = 2 \), while in [17] \( s \) is any integer.) The convergence analysis of the sequences \( \{ \theta_{2n}^{(j)} \}_{j=0}^{\infty} \) from logarithmic sequences \( \{ A_k \} \) has been given in [17]. We are not aware of analogous studies pertaining to the linear and factorial sequences in (1.2) and (1.3).

Furthermore, no results on the stability of the sequences \( \{ B_n^{(j)} \}_{j=0}^{\infty} \) and \( \{ \theta_{2n}^{(j)} \}_{j=0}^{\infty} \) have been obtained so far. Our purpose in the present work is to provide these missing analyses. We give the convergence and stability theories of the sequences \( \{ B_n^{(j)} \}_{j=0}^{\infty} \) and \( \{ \theta_{2n}^{(j)} \}_{j=0}^{\infty} \) as these are obtained from the logarithmic, linear, and factorial sequences \( \{ A_k \} \) given in (1.1)–(1.3). A nice feature of our analysis is that the treatments of the three fundamentally different classes (linear, logarithmic, factorial) are unified and simplified. In addition, based on the stability analyses of \( \{ B_n^{(j)} \}_{j=0}^{\infty} \) and \( \{ \theta_{2n}^{(j)} \}_{j=0}^{\infty} \) from linear sequences \( \{ A_k \} \), we are able to conclude that the strategy proposed in [12] for power series and Fourier series near points of singularity can be applied very effectively here too. All this is done in Sections
The study of the convergence of the W-transformation that is the subject of Section 2 turns out to be of great importance in the developments of Sections 3 and 4.

Finally, in Section 5 we provide a detailed comparison of our results on the iterated Lubkin transformation and the \(\theta\)-algorithm with the corresponding results pertaining to the Levin \(u\)-transformation.

2. Convergence analysis of the iterated Lubkin transformation

We start with the W-transformation of (1.14).

Theorem 2.1. (i) Let \(\{A_k\}\) be as in (1.1), and let \(\beta_{2+\mu}\) (\(\mu \geq 0\)) be the first nonzero \(\beta_i\) with \(i \geq 2\) in (1.11). Then

\[
W_j(\{A_s\}) - A \sim \sum_{i=0}^{\infty} w_i j^{\gamma - 2 - \mu - i} \text{ as } j \to \infty; \quad w_0 = \alpha_0 \beta_{2+\mu} \frac{(\mu+1)(\mu+2)}{\gamma-1} \neq 0.
\]

(ii) Let \(\{A_k\}\) be as in (1.2), and let \(\beta_{1+\mu}\) (\(\mu \geq 0\)) be the first nonzero \(\beta_i\) with \(i \geq 1\) in (1.12). Then

\[
W_j(\{A_s\}) - A \sim \zeta_j \sum_{i=0}^{\infty} w_i j^{\gamma - 3 - \mu - i} \text{ as } j \to \infty; \quad w_0 = \alpha_0 \beta_{1+\mu} \frac{(\mu+1)(\mu+2)}{\zeta-1} \zeta^2 \neq 0.
\]

(iii) Let \(\{A_k\}\) be as in (1.3). Then

\[
W_j(\{A_s\}) - A \sim \frac{\zeta^j}{(j!)^r} \sum_{i=0}^{\infty} w_i j^{\gamma - 3 - r - 2 - i} \text{ as } j \to \infty; \quad w_0 = \alpha_0 \zeta^3 r (r+1) \neq 0.
\]

Part (i) of Theorem 2.1 was already given in [7]. All three of (2.1)–(2.3) also follow from the analogous results of [10] and [11] that pertain to the Levin transformations. They can be proved by observing that

\[
W_j(\{A_s\}) = A - \frac{\Delta^2((A_j - A)/\Delta A_j)}{\Delta^2(1/\Delta A_j)} = \frac{\Delta^2((A_j - A)/\Delta A_j)}{\Delta^2(1/\Delta A_j)},
\]

and by invoking (1.11)–(1.13) and (1.6)–(1.8). In addition, we need the following facts that we will use again later in this work: Let

\[
g(n) \sim \sum_{i=0}^{\infty} g_i n^{\delta - i} \text{ as } n \to \infty; \quad g_0 \neq 0.
\]

First, if \(\delta \neq 0\),

\[
\Delta g(n) \sim \sum_{i=0}^{\infty} \hat{g}_i n^{\delta - i - 1} \text{ as } n \to \infty; \quad \hat{g}_0 = \delta g_0 \neq 0,
\]

and if \(\delta = 0\) and \(g_\nu\) is the first nonzero \(g_i\) with \(i \geq 1\),

\[
\Delta g(n) \sim \sum_{i=\nu}^{\infty} \hat{g}_i n^{- i - 1} \text{ as } n \to \infty; \quad \hat{g}_\nu = -\nu g_\nu \neq 0.
\]
Next, if $\zeta \neq 1$,
\begin{equation}
\Delta [\zeta^n g(n)] \sim \zeta^n \sum_{i=0}^{\infty} \hat{g}_i n^{\delta - i} \quad \text{as } n \to \infty; \quad \hat{g}_0 = (\zeta - 1) g_0 \neq 0.
\end{equation}

Finally, if $p = 1, 2, \ldots$,
\begin{equation}
\Delta [(n!)^p \zeta^n g(n)] \sim (n!)^p \zeta^n \sum_{i=0}^{\infty} \hat{g}_i n^{\delta + p - i} \quad \text{as } n \to \infty; \quad \hat{g}_0 = \zeta g_0 \neq 0.
\end{equation}
\begin{equation}
\Delta \left[ \frac{\zeta^n}{(n!)^p} \hat{g}(n) \right] \sim \frac{\zeta^n}{(n!)^p} \sum_{i=0}^{\infty} \hat{g}_i n^{\delta - i} \quad \text{as } n \to \infty; \quad \hat{g}_0 = -g_0.
\end{equation}

It follows from Theorem 2.1 that the $W$-transformation accelerates the convergence of logarithmic, linear, and factorial sequences, the acceleration of linear sequences being more effective in general. Specifically,
\begin{equation}
\frac{W_j(A_{s}) - A}{A_{j+i} - A} = O(j^{-2}) \quad \text{as } j \to \infty, \quad i \text{ fixed in (1.1)},
\end{equation}
\begin{equation}
\frac{W_j(A_{s}) - A}{A_{j+i} - A} = O(j^{-3}) \quad \text{as } j \to \infty, \quad i \text{ fixed in (1.2)},
\end{equation}
\begin{equation}
\frac{W_j(A_{s}) - A}{A_{j+3} - A} \sim r(r + 1)j^{-2} \quad \text{as } j \to \infty, \quad (1.3).
\end{equation}

Note that since $W_j(A_{s})$ is constructed from $A_{j+i}$, $0 \leq i \leq 3$, we should compare $W_j(A_{s}) - A$ with $A_{j+i} - A$, $0 \leq i \leq 3$. When $\{A_k\}$ is as in (1.1) or (1.2), $A_{j+i} - A$ are all of the same order with arbitrary fixed $i$. When $\{A_k\}$ is as in (1.3), however, $W_j(A_{s}) - A$ must be compared with $A_{j+3} - A$, the smallest of $A_{j+i} - A$, $0 \leq i \leq 3$, as $j \to \infty$, and this is what we have done in (1.3).

Finally, from (2.1) it is clear that, whether $\{A_k\}$ in (1.1) converges or not, $W_j(A_{s})$ converges to $A$ when $|\zeta| < 2$. Similarly, from (2.2) we see that $W_j(A_{s})$ converges to $A$ when $|\zeta| = 1$ provided $R\gamma < 3$, whether $\{A_k\}$ in (1.2) converges or not.

The following theorem concerns the repeated $W$-transformation as defined in (1.13) and can be proved by repeated application of Theorem 2.1. This is possible since the asymptotic expansion of $W_j(A_{s})$ as $j \to \infty$ in Theorem 2.1 is of precisely the same nature as that of $A_j$.

**Theorem 2.2.** (i) If $\{A_k\}$ is as in (1.1), then
\begin{equation}
B_n^{(j)} - A \sim \sum_{i=0}^{\infty} g_{n+j} \gamma^{-i} \quad \text{as } j \to \infty, \quad g_{n0} \neq 0,
\end{equation}
with $\gamma_0 = \gamma$, $\gamma_k = \gamma_{k-1} - 2 - \mu_k$, $k = 1, 2, \ldots$, where $\mu_k$ are some nonnegative integers, hence $R\gamma_k \leq R\gamma - 2k$, $k = 1, 2, \ldots$.

(ii) If $\{A_k\}$ is as in (1.2), then
\begin{equation}
B_n^{(j)} - A \sim \zeta^j \sum_{i=0}^{\infty} g_{n+j} \gamma^{-i} \quad \text{as } j \to \infty, \quad g_{n0} \neq 0,
\end{equation}
with $\gamma_0 = 0$, $\gamma_k = \gamma_{k-1} - 3 - \mu_k$, $k = 1, 2, \ldots$, where $\mu_k$ are some nonnegative integers, hence $R\gamma_k \leq R\gamma - 3k$, $k = 1, 2, \ldots$. 

iii) If \( \{A_k\} \) is as in (1.3), then

\[
B_n^{(j)} - A \sim \frac{\zeta^j}{j!} r \sum_{i=0}^{\infty} g_m j^{\gamma_n - i} \quad \text{as } j \to \infty, \quad g_n = a_0 \xi^3 r (r + 1)^n \neq 0,
\]

with \( \gamma_k = \gamma - k(3r + 2), \ k = 0, 1, \ldots \).

Part (i) of Theorem 2.1 was already given in [8] and [17]. Parts (ii) and (iii) are new.

Clearly, the repeated W-transformation accelerates the convergence of logarithmic, linear, and factorial sequences. Even when \( \Re \gamma \geq 0 \), hence \( \{A_k\} \) in (1.1) diverges, \( \{B_n^{(j)}\}_{j=0}^{\infty} \) will converge to \( A \) for every \( n > \frac{1}{2} \Re \gamma \) in part (i) of Theorem 2.2. Similarly, when \( \{A_k\} \) is as in (1.2) with \( |\zeta| = 1 \), \( \{B_n^{(j)}\}_{j=0}^{\infty} \) will converge to \( A \) for every \( n > \frac{1}{2} \Re \gamma \) in part (ii) of Theorem 2.2 even when \( \{A_k\} \) diverges.

In addition, analogously to (2.11)–(2.13), we have

\[
\begin{align*}
\frac{B_{n+1}^{(j)} - A}{B_n^{(j+1)} - A} &= O(j^{-2}) \quad \text{as } j \to \infty, \ i \text{ fixed (in (1.1))}, \\
\frac{B_{n+1}^{(j)} - A}{B_n^{(j+1)} - A} &= O(j^{-3}) \quad \text{as } j \to \infty, \ i \text{ fixed (in (1.2))}, \\
\frac{B_{n+1}^{(j)} - A}{B_n^{(j+3)} - A} &\sim r(r + 1)j^{-2} \quad \text{as } j \to \infty \quad \text{(in (1.3))}.
\end{align*}
\]

In other words, the sequence \( \{B_{n+1}^{(j)}\}_{j=0}^{\infty} \) converges more quickly than \( \{B_n^{(j)}\}_{j=0}^{\infty} \) for each \( n \) in all cases.

### 3. Convergence Analysis of the \( \theta \)-Algorithm

Due to the complexity of the recursion relation in (1.16), the analysis of the \( \theta \)-algorithm turns out to be quite involved. Specifically, we have two different types of sequences to worry about, namely, \( \{\theta_{2n}^{(j)}\}_{j=0}^{\infty} \) and \( \{\theta_{2n+1}^{(j)}\}_{j=0}^{\infty} \), and the two are coupled nonlinearly. Luckily, a very rigorous analysis of both types of sequences can be given, and we turn to it now.

We start by expressing \( \theta_{2n+2}^{(j)} \) in (1.16) in different forms.

**Lemma 3.1.** \( \theta_{2n+2}^{(j)} \) can be expressed as in

\[
\begin{align*}
\theta_{2n+2}^{(j)} &= \frac{1}{\Delta^2 \theta_{2n}^{(j)}} \left\{ W_j(\{\theta_{2n}^{(j)}\}) \times \Delta^2 \left(1/\Delta \theta_{2n}^{(j)} + \Delta \theta_{2n+2}^{(j)} \times \Delta \theta_{2n+1}^{(j)} \right) \right\}
\end{align*}
\]

and

\[
\theta_{2n+2}^{(j)} = \frac{\Delta \theta_{2n+2}^{(j)} \times \Delta \theta_{2n+1}^{(j)}}{\Delta^2 \theta_{2n+1}^{(j)}}.
\]

**Proof.** From (1.16) we first have

\[
\begin{align*}
\theta_{2n+2}^{(j)} &= \frac{\theta_{2n+1}^{(j+1)} \times \Delta^2 \theta_{2n+1}^{(j)} + \Delta \theta_{2n+2}^{(j)} \times \Delta \theta_{2n+1}^{(j+1)}}{\Delta^2 \theta_{2n+1}^{(j)}}.
\end{align*}
\]
Substituting $\Delta^{(j+1)} = \theta_{2n}^{(j+2)} - \theta_{2n}^{(j+1)}$ and $\Delta^2 \theta_{2n+1} = \Delta \theta_{2n+1} - \Delta \theta_{2n+1}$ in the numerator of (3.3), we obtain (3.2). Next, substituting $\theta_{2n+1}^{(j)} = \theta_{2n+1}^{(j+1)} + 1/\Delta \theta_{2n}^{(j)}$ in the numerator of (3.3), we have

$$\theta_{2n+2}^{(j)} = \frac{\Delta \theta_{2n+1}^{(j+1)} \times \Delta(1/\Delta \theta_{2n}^{(j)}) + \Delta(\theta_{2n}^{(j+1)} \times \Delta \theta_{2n+1}^{(j+1)}/\Delta^2 \theta_{2n+1}^{(j+1)})}{\Delta^2 \theta_{2n+1}^{(j+1)}}.\tag{3.4}$$

Letting now $n = 0$ and recalling that $\theta_0 = 0$, $\theta_0^{(j)} = A_j$, and hence $\theta_0^{(j)} = 1/\Delta A_j$, we have from (3.4) and (1.17) that

$$\theta_2^{(j)} = \frac{\Delta(A_{j+1} \times \Delta(1/\Delta A_j))}{\Delta^2(1/\Delta A_j)} = W_j(\{A_x\}).\tag{3.5}$$

(This is nothing but (1.17).) Using this in (3.4), the result in (3.1) follows.

The representation of $\theta_{2n+2}^{(j)}$ given in (3.3) of Lemma 3.1 and Theorem 2.1 enable us to analyze in a unified manner the convergence of the sequences $\{\theta_{2n}^{(j)}\}_{j=0}^\infty$ for all three cases of $\{A_n\}$ described in (1.1)–(1.3).

**Theorem 3.2.** (i) If $\{A_k\}$ is as in (1.1), then

$$\theta_{2n}^{(j)} - A \sim \sum_{i=0}^\infty g_{ni} j^{-\gamma_{n-i}} \text{ as } j \to \infty, \text{ } g_{n0} \neq 0,\tag{3.6}$$

$$\theta_{2n+1}^{(j)} \sim \sum_{i=0}^\infty h_{ni} j^{-\gamma_{n-i}+1} \text{ as } j \to \infty, \text{ } h_{n0} = 1/(\gamma_n g_{n0}) \neq 0,\tag{3.7}$$

with $\gamma_0 = \gamma, \gamma_k = \gamma_k-1 - 2 - \mu_k, k = 1,2,\ldots, \text{ where } \mu_k \text{ are some nonnegative integers, hence } \Re \gamma_k \leq \Re \gamma - 2k, k = 1,2,\ldots.$

(ii) If $\{A_k\}$ is as in (1.2), then

$$\theta_{2n}^{(j)} - A \sim \zeta^j \sum_{i=0}^\infty g_{ni} j^{-\gamma_{n-i}} \text{ as } j \to \infty, \text{ } g_{n0} \neq 0,\tag{3.8}$$

$$\theta_{2n+1}^{(j)} \sim \zeta^{-j} \sum_{i=0}^\infty h_{ni} j^{-\gamma_{n-i}} \text{ as } j \to \infty, \text{ } h_{n0} = 1/[(\zeta - 1) g_{n0}] \neq 0,\tag{3.9}$$

with $\gamma_0 = \gamma, \gamma_k = \gamma_k-1 - 3 - \mu_k, k = 1,2,\ldots, \text{ where } \mu_k \text{ are some nonnegative integers, hence } \Re \gamma_k \leq \Re \gamma - 3k, k = 1,2,\ldots.$

(iii) If $\{A_k\}$ is as in (1.3), then

$$\theta_{2n}^{(j)} - A \sim \zeta^j \frac{\zeta^j}{(j!)} \sum_{i=0}^\infty g_{ni} j^{-\gamma_{n-i}} \text{ as } j \to \infty, \text{ } g_{n0} = \alpha_0[(\zeta^j r + 1)\\n^2 \neq 0,\tag{3.10}$$

$$\theta_{2n+1}^{(j)} \sim \zeta^{-j} (j!)^r \sum_{i=0}^\infty h_{ni} j^{-\gamma_{n-i}} \text{ as } j \to \infty, \text{ } h_{n0} = -1/g_{n0} \neq 0,\tag{3.11}$$

with $\gamma_0 = \gamma, \gamma_k = \gamma - k(3r + 2), k = 1,2,\ldots$. Thus, in this case we also have that

$$\lim_{j \to \infty} \left[\left(\theta_{2n}^{(j)} - A\right)/(B_{2n}^{(j)} - A)\right] = 1.$$
Remark. Part (i) of this theorem was given in [17]. Parts (ii) and (iii) seem to be new. The $\gamma_n$ in (3.6) and (3.8) are not necessarily the same as those in (2.14) and (2.15) respectively.

Proof. Here we shall give a detailed proof of part (ii) of the theorem. The proofs of part (i) and part (iii) can be achieved by following the steps of the proof of part (ii) and by making the appropriate substitutions there.

We proceed by induction on $n$. From the fact that $\theta^{(j)}_0 = A_j$ and by (1.2) it is clear that (3.8) holds for $n = 0$ with $\gamma_0 = \gamma$ and $g_0 = \alpha_0 \neq 0$. From this and from the fact that $\theta^{(j)}_1 = 1/\Delta A_j$ it follows that (3.9) holds for $n = 0$ with $h_0 = 1/[(\zeta - 1)\alpha_0] \neq 0$. Let us now assume that (3.8) and (3.9) hold, and prove that they hold with $n$ replaced by $n+1$.

We begin by observing that equality is maintained in (1.16) if we subtract $A$ from the $\theta^{(2p)}_s$ there. As a result of this and of Lemma 3.1, we can write

$$\theta^{(j)}_{2n+2} - A = \frac{1}{\Delta^2 \theta^{(j)}_{2n+1}} \left\{ [W_j(\{\theta^{(s)}_{2n}\}) - A] \Delta^2 (1/\Delta \theta^{(j)}_{2n}) + \Delta [(\theta^{(j+1)}_{2n} - A)(\Delta \theta^{(j+1)}_{2n-1})] \right\}.$$  

Now by part (ii) of Theorem 2.4 we have

$$P_j \equiv W_j(\{\theta^{(s)}_{2n}\}) - A \sim \zeta^j \sum_{i=0}^{\infty} p_{ij} \gamma_{n-3-i} \text{ as } j \to \infty,$$

and

$$Q_j \equiv \Delta^2 (1/\Delta \theta^{(j)}_{2n}) \sim \zeta^{-j} \sum_{i=0}^{\infty} q_{ij} \gamma_{n-i} \text{ as } j \to \infty.$$

Thus

$$P_j Q_j \sim \sum_{i=0}^{\infty} u'_{ij} \gamma_{3-i} \text{ as } j \to \infty.$$

Next, by the induction hypothesis we have

$$R_j \equiv \theta^{(j+1)}_{2n} - A \sim \zeta^j \sum_{i=0}^{\infty} r_{ij} \gamma_{n-i} \text{ as } j \to \infty,$$

and

$$S_j \equiv \Delta \theta^{(j+1)}_{2n-1} \sim \zeta^{-j} \sum_{i=0}^{\infty} s_{ij} \gamma_{n-1-i} \text{ as } j \to \infty,$$

and hence

$$\Delta(R_j S_j) \sim \sum_{i=0}^{\infty} u''_{ij} \gamma_{n-1-i-1} \text{ as } j \to \infty.$$
Combining (3.19) and (3.20) in (3.12), we obtain

\[(3.20)\]

nonnegative integer \(\mu\)

In addition, since \(\theta^{(j)}_{2n+1}\) satisfies (3.14) by the induction hypothesis,

\[(3.14)\]

Next, by (3.22) we have

\[(3.23)\]

with \(\gamma_{n+1} = \gamma_n - 3 - \mu_{n+1}\) for some nonnegative integer \(\mu_{n+1}\).

As for \(\theta^{(j)}_{2n+2}\), we first have the asymptotic equality

\[(3.24)\]

Next, by (3.22) we have

\[(3.25)\]

Combining (3.21) and (3.22) in (3.12), we obtain

\[(3.21)\]

which gives the desired result for \(\theta^{(j)}_{2n+2}\), namely,

\[(3.22)\]

As for \(\theta^{(j)}_{2n+3}\), we start with

\[(3.23)\]

By the induction hypothesis we first have

\[(3.24)\]

and, as a result,

\[(3.27)\]

which is the desired result for \(\theta^{(j)}_{2n+3}\). This completes the proof of part (ii) of the theorem.

As the representation of \(\theta^{(j)}_{2n+2}\) given in (3.22) looks simpler than that in (3.14), one may wonder whether it is not easier to use (3.22) in the proof of Theorem 3.2. It turns out that the convergence result produced by (3.22) is inferior to that stated in Theorem 3.2. The representation in (3.22) turns out to be useful in the stability analysis that we present in the next section, however.
4. Stability

An issue of major importance in convergence acceleration is that of stability. By studying this issue carefully, we may understand why convergence acceleration methods behave the way they do, and we can also design ways of improving the convergence of these methods, at least in some cases. This has been done successfully in the papers \[12\] and [13] by the author in connection with the $d$-transformation of Levin and Sidi [6].

Our purpose now is to study the stability of the iterated $W$-transformation and the $\theta$-algorithm as these are applied to the sequences $\{A_k\}$ that have been treated in the previous sections. It turns out that both methods can be analyzed simultaneously with respect to stability.

From (4.1) and (4.2) we have

\begin{equation}
\lambda_n^{(j)} = \frac{\Delta(1/\Delta B_n^{(j)})}{\Delta^2(1/\Delta B_n^{(j)})} \quad \text{and} \quad \mu_n^{(j)} = \frac{\Delta(1/\Delta B_n^{(j+1)})}{\Delta^2(1/\Delta B_n^{(j)})}.
\end{equation}

Similarly, from (3.2) we have

\begin{equation}
\theta_{2n+2}^{(j)} = \lambda_n^{(j)} \theta_{2n}^{(j)} + \mu_n^{(j)} \theta_{2n+2}^{(j)}.
\end{equation}

If we denote both $B_n^{(j)}$ and $\theta_{2n}^{(j)}$ by $Q_n^{(j)}$, we realize that (4.1) and (4.2) can be expressed as in

\begin{equation}
Q_{n+1}^{(j)} = \lambda_n^{(j)} Q_n^{(j+1)} + \mu_n^{(j)} Q_n^{(j+2)}; \quad \lambda_n^{(j)} + \mu_n^{(j)} = 1,
\end{equation}

with the appropriate $\lambda_n^{(j)}$ and $\mu_n^{(j)}$.

Starting with the fact that $Q_0^{(j)} = A_j$, $j = 0, 1, \ldots$, we can easily see by induction that

\begin{equation}
Q_n^{(j)} = \sum_{i=0}^{n-1} \gamma_{ni}^{(j)} A_{j+n+i} ; \quad \sum_{i=0}^{n-1} \gamma_{ni}^{(j)} = 1,
\end{equation}

for some $\gamma_{ni}^{(j)}$ that depend nonlinearly on $A_k$, $j \leq k \leq j + 3n$. As has been observed in the context of other extrapolation methods, the way $Q_n^{(j)}$ has been expressed in (4.4) is very suitable for the analysis of stability. The quantities of relevance to stability of the $Q_n^{(j)}$ are

\begin{equation}
\Gamma_n^{(j)} = \sum_{i=0}^{n} |\gamma_{ni}^{(j)}|,
\end{equation}

in the following sense. If $\hat{A}_k = A_k + \epsilon_k$ are the computed values of the $A_k$, then the application of the iterated $W$-transformation and the $\theta$-algorithm to $\{\hat{A}_k\}$ produces the approximations $\tilde{Q}_n^{(j)}$ that are given by

\begin{equation}
\tilde{Q}_n^{(j)} \approx \sum_{i=0}^{n} \gamma_{ni}^{(j)} \hat{A}_{j+n+i} = Q_n^{(j)} + \sum_{i=0}^{n} \gamma_{ni}^{(j)} \epsilon_{j+n+i}.
\end{equation}
for all practical purposes. (This is so since the $\gamma^{(j)}_{nl}$, even though they depend on the $A_k$, do not vary appreciably with small errors in the $A_k$.) Thus

\[ |\bar{Q}^{(j)}_n - Q^{(j)}_n| \leq \frac{\Gamma^{(j)}_n}{\varepsilon}, \quad \varepsilon = \max\{|\epsilon_k| : j + n \leq k \leq j + 2n|\}. \]

That is, $\Gamma^{(j)}_n$ determines how close $\bar{Q}^{(j)}_n$ is to $Q^{(j)}_n$. For additional information on the meaning of $\Gamma^{(j)}_n$ we refer to Section 4 of Sidi [14].

We next state a result on the behavior of $\gamma^{(j)}_{nl}$ as in part (i) of Theorem 2.2 or Theorem 3.2. We leave its details to the reader.

Lemma 4.1. Let $P^{(j)}_n(z) = \sum_{n=0}^{\infty} \gamma^{(j)}_{nl} A_j z^i$. Then

\[ P^{(j)}_{n+1}(z) = \lambda^{(j)}_n P^{(j+1)}_n(z) + \mu^{(j)}_n z P^{(j+2)}_n(z). \]

Proof. By (4.3) and (4.4) we have

\[ \bar{Q}^{(j)}_n - Q^{(j)}_n = \Gamma^{(j)}_n \varepsilon, \quad \varepsilon = \max\{|\epsilon_k| : j + n \leq k \leq j + 2n|\}. \]

Lemma 4.2. (i) If $\{A_k\}$ is as in (1.1), then

\[ \lambda^{(j)}_n \sim \frac{j}{\gamma_n} \quad \text{and} \quad \mu^{(j)}_n \sim \frac{j}{\gamma_n} \quad \text{as} \quad j \to \infty, \quad n \geq 0, \]

with $\gamma_k$ as in part (i) of Theorem 2.2 or Theorem 3.2.

(ii) If $\{A_k\}$ is as in (1.2), then

\[ \lambda^{(j)}_n \sim \frac{\zeta}{\zeta - 1} \quad \text{and} \quad \mu^{(j)}_n \sim \frac{1}{\zeta - 1} \quad \text{as} \quad j \to \infty, \quad n \geq 0. \]

(iii) If $\{A_k\}$ is as in (1.3), then

\[ \lambda^{(j)}_n = o(1) \quad \text{and} \quad \mu^{(j)}_n \sim 1 \quad \text{as} \quad j \to \infty, \quad n \geq 0. \]

The proof of this lemma can be achieved by employing the results of Theorems 2.2 and 3.2. We leave its details to the reader.

The main stability results are given in the next theorem.
Theorem 4.3. (i) If \( \{A_k\} \) is as in (1.1), then
\[
(4.14) \quad P_n^{(j)}(z) \sim \left( \prod_{k=0}^{n-1} \gamma_k \right)^{-1} (1 - z)^n j^n \quad \text{and} \quad \Gamma_n^{(j)} \sim \left( \prod_{k=0}^{n-1} \gamma_k \right)^{-1} (2j)^n \quad \text{as} \quad j \to \infty.
\]

(ii) If \( \{A_k\} \) is as in (1.2), then
\[
(4.15) \quad P_n^{(j)}(z) \sim \left( \frac{\zeta - z}{\zeta - 1} \right)^n \quad \text{and} \quad \Gamma_n^{(j)} \sim \left( \frac{\zeta + 1}{\zeta - 1} \right)^n \quad \text{as} \quad j \to \infty.
\]
(Of course, when \( \zeta = -1 \), \( \Gamma_n^{(j)} \sim 1 \) as \( j \to \infty \).)

(iii) If \( \{A_k\} \) is as in (1.3), then
\[
(4.16) \quad P_n^{(j)}(z) \sim z^n \quad \text{and} \quad \Gamma_n^{(j)} \sim 1 \quad \text{as} \quad j \to \infty.
\]

Proof. The proofs of all three parts can be carried out by combining Lemma 4.1 and Lemma 4.2 and by using induction on \( n \). We leave the details to the reader. \( \Box \)

We can conclude from part (i) of Theorem 4.3 that neither the iterated \( W \)-transformation nor the \( \theta \)-algorithm is stable when applied to the logarithmic sequences in (1.1). They may achieve quite high numerical accuracy when \( |\Im \gamma| \) is large, as in this case the factor \( \left| \prod_{k=0}^{n-1} \gamma_k \right|^{-1} \) becomes small causing \( \Gamma_n^{(j)} \) to be small, even though \( \sup \Gamma_n^{(j)} = \infty \). This conclusion is the same as that reached in Sidi [13] for the Richardson extrapolation process.

From part (ii) of Theorem 4.3 we conclude that both methods are stable when applied to the linear sequences in (1.2). When \( \zeta \) is close to 1, however, \( \Gamma_n^{(j)} \) may be very large even though \( \sup \Gamma_n^{(j)} < \infty \). In order to stabilize the approximations \( Q_n^{(j)} \) we propose to apply the methods to the subsequences \( \{A_{sk}\}_{k=0}^\infty \) for some positive integer \( s \geq 2 \) such that \( \zeta^s \neq 1 \) and is farther from 1 than \( \zeta \) is. For \( \{A_{sk}\}_{k=0}^\infty \) we will have in this case
\[
(4.17) \quad A_{sn} \sim A + (\zeta^s)^n \sum_{i=0}^\infty a'_i n^{s-i} \quad \text{as} \quad n \to \infty, \quad a'_0 = a_0 s^s \neq 0.
\]

An analogous strategy was already proposed in Sidi [12] in the application of the Levin-Sidi [6] \( d \)-transformation to power series and Fourier series and their generalizations.

Part (iii) of Theorem 4.3 implies that, when applied to the factorial sequences in (1.3), the methods are stable.

5. Comparison with the Levin \( u \)-transformation

The results we have obtained for the iterated \( W \)-transformation and the \( \theta \)-algorithm are similar to those pertaining to the Levin \( u \)-transformation that is defined in (1.18). We provide the latter here for comparison and completeness. Before we do that we also note that
\[
(5.1) \quad u_n^{(j)} = \sum_{i=0}^n \gamma_n^{(j)} A_{j+i}; \quad \gamma_n^{(j)} = \frac{(-1)^n i(n+i)(j+i)n+2}{\Delta A_{j+i}}/\Delta^2(jn^{n+2}/\Delta A_j), \quad i = 0, 1, \ldots , n.
\]
Theorem 5.1. (i) Let \( \{A_k\} \) be as in (1.1), and let \( \beta_{n+\mu} \) \( (\mu \geq 0) \) be the first nonzero \( \beta_i \) with \( i \geq n \) in (1.1). Then

\[
u_n(j) - A \sim \sum_{i=0}^{\infty} w_i j^{-n-\mu-i} \quad \text{as} \quad j \to \infty; \quad w_0 = (-1)^n \alpha_0 \beta_{n+\mu} \frac{(\mu+1)n}{(\gamma_n) n} \neq 0,
\]

\[
P_n(j) \sim \frac{j^n}{(\gamma_n) n} (z-1)^n \quad \text{and} \quad \Gamma_n(j) \sim \frac{(2j)^n}{|(-\gamma_n) n|} \quad \text{as} \quad j \to \infty.
\]

(ii) Let \( \{A_k\} \) be as in (1.2), and let \( \beta_{n-1+\mu} \) \( (\mu \geq 0) \) be the first nonzero \( \beta_i \) with \( i \geq n - 1 \) in (1.2). Then

\[
u_n(j) - A \sim \zeta j \sum_{i=0}^{\infty} w_i j^{-2n+1-\mu-\nu-i} \quad \text{as} \quad j \to \infty; \quad w_0 = \alpha_0 \beta_{n-1+\mu} \frac{\zeta^n}{(\gamma_n) n} \neq 0,
\]

\[
P_n(j) \sim \left( \frac{\zeta - \zeta}{\zeta - 1} \right)^n \quad \text{and} \quad \Gamma_n(j) \sim \left( \frac{\zeta + 1}{\zeta - 1} \right)^n \quad \text{as} \quad j \to \infty.
\]

(iii) Let \( \{A_k\} \) be as in (1.3), and let \( \beta_{n-1+\mu} \) \( (\mu \geq 0) \) be the first nonzero \( \beta_i \) with \( i \geq n - 1 \) in (1.3). Then

\[
u_n(j) - A \sim (\Delta A_{j+n}) \sum_{i=0}^{\infty} \delta_i j^{-n-r-i} \quad \text{as} \quad j \to \infty;
\]

\[
\delta_0 = -\zeta \cdot (-r-1) n \neq 0, \quad n \leq r + 1,
\]

\[
u_n(j) - A \sim (\Delta A_{j+n}) \sum_{i=0}^{\infty} \delta_i j^{-2n+1-\mu-i} \quad \text{as} \quad j \to \infty;
\]

\[
\delta_0 = (-1)^n \beta_{n-1+\mu} (\mu+1)n \neq 0, \quad n > r + 1,
\]

\[
P_n(j) \sim z^n \quad \text{and} \quad \Gamma_n(j) \sim 1 \quad \text{as} \quad j \to \infty.
\]

As can be seen from this theorem, the \( u \)-transformation accelerates the convergence of \( \{A_k\} \) in all cases.

Since the approximation \( \nu_n(j) \) is determined from \( A_k, \) \( j \leq k \leq j + n + 1, \) and the approximation \( Q_n(j) (B_n(j) \) or \( \theta_2(j)) \) is determined from \( A_k, \) \( j \leq k \leq j + 3n, \) we should compare the sequences \( \{u_{3n-1}(j)\}_{j=0}^{\infty} \) and \( \{Q_n(j)\}_{j=0}^{\infty}. \) From previous results we have, for \( j \to \infty, \)

\[
Q_n(j) - A = O(j^{\gamma-2n}) \quad \text{and} \quad u_{3n-1}(j) - A = O(j^{\gamma-3n+1}) \quad \text{(for (1.1)),}
\]

\[
Q_n(j) = A = O(\zeta j j^{\gamma-3n}) \quad \text{and} \quad u_{3n-1}(j) - A = O(j^{\gamma-6n+3}) \quad \text{(for (1.2)),}
\]

\[
Q_n(j) - A = O\left(\frac{\zeta_j}{(j!)^n} j^{\gamma-(3n+2)n}\right) \quad \text{and} \quad u_{3n-1}(j) - A = O\left(\frac{\zeta_j}{(j!)^n} j^{\gamma-(3n+2)n-(4n-r-3)}\right), \quad n > r + 1 \quad \text{(for (1.3)).}
