

## NOTES ON SOME NEW KINDS OF PSEUDOPRIMES

ZHENXIANG ZHANG

ABSTRACT. J. Browkin defined in his recent paper (Math. Comp. **73** (2004), pp. 1031–1037) some new kinds of pseudoprimes, called Sylow  $p$ -pseudoprimes and elementary Abelian  $p$ -pseudoprimes. He gave examples of strong pseudoprimes to many bases which are not Sylow  $p$ -pseudoprime to two bases only, where  $p = 2$  or  $3$ .

In this paper, in contrast to Browkin's examples, we give facts and examples which are unfavorable for Browkin's observation to detect compositeness of odd composite numbers. In Section 2, we tabulate and compare counts of numbers in several sets of pseudoprimes and find that most strong pseudoprimes are also Sylow 2-pseudoprimes to the same bases. In Section 3, we give examples of Sylow  $p$ -pseudoprimes to the first several prime bases for the first several primes  $p$ . We especially give an example of a strong pseudoprime to the first six prime bases, which is a Sylow  $p$ -pseudoprime to the same bases for all  $p \in \{2, 3, 5, 7, 11, 13\}$ . In Section 4, we define  $n$  to be a  $k$ -fold Carmichael Sylow pseudoprime, if it is a Sylow  $p$ -pseudoprime to all bases prime to  $n$  for all the first  $k$  smallest odd prime factors  $p$  of  $n - 1$ . We find and tabulate all three 3-fold Carmichael Sylow pseudoprimes  $< 10^{16}$ . In Section 5, we define a positive odd composite  $n$  to be a Sylow uniform pseudoprime to bases  $b_1, \dots, b_k$ , or a Syl-upsp( $b_1, \dots, b_k$ ) for short, if it is a Syl $_p$ -psp( $b_1, \dots, b_k$ ) for all the first  $\omega(n - 1) - 1$  small prime factors  $p$  of  $n - 1$ , where  $\omega(n - 1)$  is the number of distinct prime factors of  $n - 1$ . We find and tabulate all the 17 Syl-upsp(2, 3, 5)'s  $< 10^{16}$  and some Syl-upsp(2, 3, 5, 7, 11)'s  $< 10^{24}$ . Comparisons of effectiveness of Browkin's observation with Miller tests to detect compositeness of odd composite numbers are given in Section 6.

### 1. INTRODUCTION

In August 2002, M. Agrawal, N. Kayal and N. Saxena [1] presented a deterministic polynomial time primality proof algorithm. This was a theoretical breakthrough, but was pointed out by Günter M. Ziegler [18] that, "it is not yet suitable for use in practice". A. Stiglic [13] pointed out that the Rabin-Miller test [8, 12] is probably the primality test the most used in practice.

Let  $n > 1$  be an odd integer and let  $b_1, \dots, b_k$  be some reduced residues modulo  $n$ . If  $n$  is composite and the congruence

$$(1.1) \quad b_j^{n-1} \equiv 1 \pmod{n}$$

holds for  $1 \leq j \leq k$ , then we say that  $n$  is a  $\text{psp}(b_1, \dots, b_k)$  (a (Fermat) pseudoprime to bases  $b_1, \dots, b_k$ ), or write

$$n \in \text{psp}(b_1, \dots, b_k).$$

If  $n$  is composite with  $n - 1 = 2^s d$  and  $d$  odd, and

$$(1.2) \quad \text{either } b_j^d \equiv 1 \pmod{n} \text{ or } b_j^{2^{r_j} d} \equiv -1 \pmod{n} \text{ for some } r_j = 0, 1, \dots, s - 1$$

holds for  $1 \leq j \leq k$ , then we say that  $n$  passes the Miller test to bases  $b_j$  and that  $n$  is an  $\text{spsp}(b_1, \dots, b_k)$  (a strong pseudoprime to bases  $b_1, \dots, b_k$ ) [8], or write

$$n \in \text{spsp}(b_1, \dots, b_k).$$

(The original test of Miller [8] was somewhat more complicated and was a deterministic, ERH-based test; see [6, Section 3.4].)

The definition of strong pseudoprimes is based on the fact that in a finite field the equation  $X^2 = 1$  has at most two solutions, 1 and  $-1$ . Browkin [5] defined more general pseudoprimes using the fact that, in a finite field, the equation  $X^r = 1$  has at most  $r$  solutions for every  $r \geq 2$ . Let  $p$  be a prime such that  $n - 1 = p^r m$  with  $r > 0$  and  $p \nmid m$ , and let

$$(1.3) \quad a_j = b_j^m$$

for  $1 \leq j \leq k$ . Let

$$c_j = \begin{cases} 1, & \text{if } a_j = 1, \\ a_j^{\text{ord}(a_j)/p}, & \text{if } p \mid \text{ord}(a_j). \end{cases}$$

The following conditions hold if  $n$  is a prime.

$$(1') \quad a_j^{p^r} = 1 \text{ for } 1 \leq j \leq k.$$

(2'') If, say,  $\text{ord}(a_1) \geq \text{ord}(a_j)$ , for  $1 \leq j \leq k$ , then  $a_2, \dots, a_k$  belong to the group generated by  $a_1$ .

(3'') If, say,  $\text{ord}(c_1) \geq \text{ord}(c_j)$ , for  $1 \leq j \leq k$ , then  $c_2, \dots, c_k$  belong to the group generated by  $c_1$ .

$$(4'') \quad \text{For } 1 \leq j \leq k, \text{ if } \text{ord}(c_j) = p, \text{ then } 1 + c_j + c_j^2 + \dots + c_j^{p-1} = 0.$$

Browkin [5, §2] defined a composite number  $n$  to be a *Sylow  $p$ -pseudoprime to bases  $b_1, \dots, b_k$* , denoted

$$(1.4) \quad n \in \text{Syl}_p\text{-psp}(b_1, \dots, b_k),$$

if  $n$  satisfies (1'), (2'') and (4''); and to be an *elementary Abelian  $p$ -pseudoprime to bases  $b_1, \dots, b_k$* , denoted

$$n \in \text{Elem}_p\text{-psp}(b_1, \dots, b_k),$$

if  $n$  satisfies (1'), (3'') and (4''). Note that

$$(1.5) \quad \text{a composite number } n \text{ satisfies (1')} \iff n \in \text{psp}(b_1, \dots, b_k).$$

Browkin [5] gave examples of strong pseudoprimes to many bases which are not Sylow  $p$ -pseudoprime to two bases only, where  $p = 2$  or  $3$ . More precisely, in [5, §§4-5] he checked the numbers  $\psi_m$  for  $2 \leq m \leq 8$  and upper bounds of  $\psi_9$ ,  $\psi_{10}$  and  $\psi_{11}$  given in [7] and found that every number of which does not belong to some  $\text{Syl}_p\text{-psp}(b_1, b_2)$  for  $p = 2$  or  $3$  and  $b_1, b_2 \in \{2, 3, 5\}$ , where  $\psi_m$  is the smallest strong pseudoprime to all the first  $m$  prime bases [11]. In [5, §5] he then verified that for every number  $n$  (with one exception) in [7, Table 1: all strong pseudoprimes  $n < 10^{12}$  to bases 2, 3 and 5] there exists a prime  $p \in \{2, 3, 5\}$  and a

basis  $b_1, b_2 \in \{2, 3, 5\}$  such that  $n \notin \text{Syl}_p\text{-psp}(b_1, b_2)$ . The exceptional number (No. 73 in the list)  $n \notin \text{Syl}_{13}\text{-psp}(2, 3)$ , where 13 is the third smallest prime divisor of  $n - 1$ .

In this paper, in contrast to Browkin’s examples, we give facts and examples which are unfavorable for Browkin’s observation to detect compositeness of odd composite numbers. In Section 2, we tabulate and compare counts of numbers in several sets of pseudoprimes and find that most strong pseudoprimes are also Sylow 2-pseudoprimes to the same bases. In Section 3, we give examples of Sylow  $p$ -pseudoprimes to the first several prime bases for the first several primes  $p$ . We especially give an example of strong pseudoprime to the first six prime bases, which is a Sylow  $p$ -pseudoprime to the same bases for all  $p \in \{2, 3, 5, 7, 11, 13\}$ . In Section 4, we define  $n$  to be a  $k$ -fold Carmichael Sylow pseudoprime, if it is a Sylow  $p$ -pseudoprime to all bases prime to  $n$  for all the first  $k$  smallest odd prime factors  $p$  of  $n - 1$ . We find and tabulate all three 3-fold Carmichael Sylow pseudoprimes  $< 10^{16}$ . In Section 5, we define a positive odd composite  $n$  to be a Sylow uniform pseudoprime to bases  $b_1, \dots, b_k$ , or a Syl-upsp( $b_1, \dots, b_k$ ) for short, if it is a Syl $_p$ -psp( $b_1, \dots, b_k$ ) for all the first  $\omega(n - 1) - 1$  small prime factors  $p$  of  $n - 1$ , where  $\omega(n - 1)$  is the number of distinct prime factors of  $n - 1$ . We find and tabulate all the 17 Syl-upsp(2, 3, 5)’s  $< 10^{16}$  and some Syl-upsp(2, 3, 5, 7, 11)’s  $< 10^{24}$ . Comparisons of effectiveness of Browkin’s observation with Miller tests to detect compositeness of odd composite numbers are given in Section 6.

2. SYLOW 2-PSEUDOPRIMES

Let  $\mathcal{S}$  be a set of some odd composites and let  $b_j$  be the  $j$ th prime. Define

$$\begin{aligned} h_0(\mathcal{S}, t) &= \# \mathcal{S} \cap \text{spsp}(b_1, \dots, b_t), \\ h_1(\mathcal{S}, t) &= \# \mathcal{S} \cap \text{Elem}_2\text{-psp}(b_1, \dots, b_t), \\ h_2(\mathcal{S}, t) &= \# \mathcal{S} \cap \text{Syl}_2\text{-psp}(b_1, \dots, b_t). \end{aligned}$$

Then we have

$$h_2(\mathcal{S}, t) \leq h_1(\mathcal{S}, t) \leq h_0(\mathcal{S}, t).$$

Let  $\mathcal{S}_1$  be the set of 264239 psp(2)’s  $< 10^{13}$  [10], let  $\mathcal{S}_2$  be the set of 246683 Carmichael numbers  $< 10^{16}$  [9], and let  $\mathcal{S}_3$  be the set of 52593 spsp(2, 3)’s  $< 10^{16}$

TABLE 1. The functions  $h_i(\mathcal{S}_j, t)$

$t$	1	2	3	4	5	6	7	8
$b_t$	2	3	5	7	11	13	17	19
$h_0(\mathcal{S}_1, t)$	58892	2696	240	24	2	1	0	0
$h_1(\mathcal{S}_1, t)$	58892	2696	240	24	2	1	0	0
$h_2(\mathcal{S}_1, t)$	58892	2436	198	15	2	1	0	0
$h_0(\mathcal{S}_2, t)$	4185	435	99	25	9	3	1	0
$h_1(\mathcal{S}_2, t)$	4185	435	99	25	9	3	1	0
$h_2(\mathcal{S}_2, t)$	4185	375	88	25	9	3	1	0
$h_0(\mathcal{S}_3, t)$	52593	52593	4603	606	107	11	2	1
$h_1(\mathcal{S}_3, t)$	52593	52593	4603	606	107	11	2	1
$h_2(\mathcal{S}_3, t)$	52593	47614	3866	413	61	10	1	0

[3]. We list the values of the functions  $h_i(\mathcal{S}_j, t)$  for  $0 \leq i \leq 2$  and  $1 \leq j \leq 3$  in Table 1.

*Remark 2.1.* From Table 1 we have  $h_1(\mathcal{S}_j, t) = h_0(\mathcal{S}_j, t)$  for  $1 \leq j \leq 3$ . But there do exist strong pseudoprimes  $> 10^{16}$  which are not elementary Abelian 2-pseudoprimes to the same bases. However such numbers are few.

*Remark 2.2.* From Table 1 we also see that most strong pseudoprimes are also Sylow 2-pseudoprimes to the same bases.

3. SYLOW  $p$ -PSEUDOPRIMES TO SEVERAL BASES FOR SEVERAL  $p$

We have checked all the 52593  $\text{spsp}(2, 3)$ 's  $< 10^{16}$  given by Bleichenbacher [3] (also available in the package of [4]). In contrast to Browkin's observation [5, §5] on all the 101 strong pseudoprimes  $n < 10^{12}$  to bases 2, 3 and 5, we find all 43 numbers  $< 10^{16}$  which are  $\text{Syl}_p\text{-psp}(2, 3, 5)$ 's for all  $p \in \{2, 3, 5\}$ . Two of the 43 numbers are  $\text{Syl}_p\text{-psp}(2, 3, 5, 7)$ 's for all  $p \in \{2, 3, 5\}$  listed in Table 2, and another two of the 43 numbers are  $\text{Syl}_p\text{-psp}(2, 3, 5)$ 's for all  $p \in \{2, 3, 5, 7, 11\}$  listed in Table 3.

We have also checked all the 44134  $\text{K3-spsp}(2, 3, 5, 7, 11)$ 's  $< 10^{24}$  obtained in our obvious paper [14] and all 330670  $\text{K3-spsp}(2, 3, 5, 7, 11, 13)$ 's  $< 10^{28}$  computed recently by us. (We call  $n = p \cdot q$  a  $\text{Kk}$ -number [14], if both  $p$  and  $q$  are primes with  $q - 1 = k(p - 1)$ . A  $\text{Kk-spsp}$  is a  $\text{Kk}$ -number and an  $\text{spsp}$ .) We find a 24-digit number  $N_1 \in \text{Syl}_p\text{-psp}(2, 3, 5, 7, 11)$  for all  $p \in \{2, 3, 5, 7, 11\}$ , and a 27-digit number  $N_2 \in \text{Syl}_p\text{-psp}(2, 3, 5, 7, 11, 13)$  for all  $p \in \{2, 3, 5, 7, 11, 13\}$ ; see Examples 3.1 and 3.2 below.

**Example 3.1.** Let

$$N_1 = 5387\ 86482\ 20306\ 86028\ 51041 = 423787085773 \cdot 1271361257317,$$

and let  $B = \{b_1 < \dots < b_5\} = \{2, 3, 5, 7, 11\}$ . Then

$$N_1 - 1 = 2^5 \cdot 3 \cdot 5 \cdot 7 \cdot 11 \cdot 8573 \cdot 4119397 \cdot 412779629$$

and  $b_j^{N_1-1} \equiv 1 \pmod{N_1}$  for  $1 \leq j \leq 5$ , i.e.,  $N_1 \in \text{psp}(2, 3, 5, 7, 11)$ . Next one can easily verify that, for all  $p \in B$ , Conditions (2'') and (4'') hold for  $k = 5$ . So, we have  $N_1 \in \text{Syl}_p\text{-psp}(2, 3, 5, 7, 11)$  for all  $p \in B$ .

**Example 3.2.** Let

$$N_2 = 54\ 33085\ 44680\ 44402\ 66202\ 96161 = 13457445828493 \cdot 40372337485477.$$

TABLE 2. List of all  $\text{Syl}_p\text{-psp}(2, 3, 5, 7)$ 's  $< 10^{16}$  for all  $p \in \{2, 3, 5\}$

number $n$	$n - 1$
4251161764252561 = 24643637 · 172505453	$2^4 \cdot 3 \cdot 5 \cdot 17 \cdot 31 \cdot 53 \cdot 353 \cdot 563 \cdot 3191$
7139051111621521 = 31935317 · 223547213	$2^4 \cdot 3^2 \cdot 5 \cdot 7 \cdot 13 \cdot 17 \cdot 23 \cdot 83 \cdot 1151 \cdot 2917$

TABLE 3. List of all  $\text{Syl}_p\text{-psp}(2, 3, 5)$ 's  $< 10^{16}$  for all  $p \in \{2, 3, 5, 7, 11\}$

number $n$	$n - 1$
8724724360769341 = 66048181 · 132096361	$2^2 \cdot 3^2 \cdot 5 \cdot 7 \cdot 11 \cdot 19 \cdot 23 \cdot 29 \cdot 31 \cdot 229 \cdot 6997$
9048616783520161 = 54919993 · 164759977	$2^5 \cdot 3 \cdot 5 \cdot 7 \cdot 11 \cdot 41 \cdot 83 \cdot 1289 \cdot 55813$

Then

$$N_2 - 1 = 2^5 \cdot 3 \cdot 5 \cdot 7 \cdot 11 \cdot 13^3 \cdot 293 \cdot 6053 \cdot 632329 \cdot 5966273.$$

It is easy to verify that  $N_2 \in \text{Syl}_p\text{-psp}(2, 3, 5, 7, 11, 13)$  for all  $p \in \{2, 3, 5, 7, 11, 13\}$ .

*Remark 3.1.* The number  $N_1$  in Example 3.1 is also an  $\text{spsp}(2, 3, 5, 7, 11)$  but not an  $\text{spsp}(13)$ . So, only six Miller tests (1.2) would detect the compositeness of  $N_1$ . Since  $N_1 \in \text{Syl}_p\text{-psp}(2, 3, 5, 7, 11)$  for all  $p \in \{2, 3, 5, 7, 11\}$ , it would be much more expensive to use Browkin’s observation to detect the compositeness of  $N_1$  than to use only Miller tests. The same arguments can be used to  $N_2$  in Example 3.2, noting that  $N_2$  is an  $\text{spsp}(2, 3, 5, 7, 11, 13)$  but not an  $\text{spsp}(17)$ . Moreover, Tables 2 and 3, as well as Examples 3.1 and 3.2 suggest that, for any  $k \geq 1$ , there would exist Sylow  $p$ -pseudoprimes to the first  $k$  prime bases for all the first  $k$  primes  $p$ .

#### 4. CARMICHAEL SYLOW $p$ -PSEUDOPRIMES FOR ODD $p$

There are positive odd numbers  $n$  such that some of the first several smallest odd primes  $(3, 5, 7, \dots)$  do not divide  $n - 1$ . To make Browkin’s observation applicable to these numbers, one may consider the first several smallest odd prime factors  $p$  of  $n - 1$ . Unfortunately, there exist Sylow  $p$ -pseudoprimes  $n$  to all bases prime to  $n$  for all the first several smallest odd prime factors  $p$  of  $n - 1$ .

**Lemma 4.1.** *Let  $n = q_1 q_2 \dots q_s$  be a Carmichael number, and let  $p$  be an odd prime such that  $p|n - 1$  but  $p \nmid q_j - 1$  for  $1 \leq j \leq s$ . Write*

$$\{b : 1 \leq b \leq n - 1, \text{gcd}(b, n) = 1\} = \{1 = b_1 < b_2 < \dots < b_k\}.$$

*Then  $n \in \text{Syl}_p\text{-psp}(b_1, b_2, \dots, b_k)$ , i.e.,  $n$  is a Sylow  $p$ -pseudoprime to all bases prime to  $n$ .*

*Proof.* Write  $n - 1 = p^r m$ . Since  $n$  is a Carmichael number, Condition (1') holds for all  $b_j$ . Since  $p \nmid q_j - 1$ , we have  $q_j - 1 \mid m$ , thus  $a_j = c_j = 1$  for  $1 \leq j \leq k$ , i.e., Conditions (2'') and (4'') hold trivially for the set of  $b_j$ .  $\square$

**Definition 4.1.** Let  $n$  be a Carmichael number, and let  $p$  be an odd prime such that  $p|n - 1$ . We call  $n$  a *Carmichael Sylow  $p$ -pseudoprime* if it is a Sylow  $p$ -pseudoprime to all bases prime to  $n$ . We call  $n$  a  *$k$ -fold Carmichael Sylow pseudoprime* if it is a Carmichael Sylow  $p$ -pseudoprime for all the first  $k$  smallest odd prime factors  $p$  of  $n - 1$ .

**Example 4.1.** Let  $n = 278545 = 5 \cdot 17 \cdot 29 \cdot 113$ . Then  $n - 1 = 2^4 \cdot 3 \cdot 7 \cdot 829$ . It is easy to check that  $n$  is the smallest Carmichael Sylow 3-pseudoprime. It is also a Carmichael Sylow 829-pseudoprime. But  $n$  is not a Carmichael Sylow 7-pseudoprime, since we have at least  $n \notin \text{Syl}_7\text{-spsp}(2)$ . So,  $n$  is a 1-fold (but not a 2-fold) Carmichael Sylow pseudoprime.

Let  $p$  be an odd prime, and let  $p_j$  be the  $j$ th prime. Define

$$f_1(p) = \#\{n : n \text{ is a Carmichael number} < 10^{16} \text{ with } p|n - 1\}$$

and

$$f_2(p) = \#\{n : n \text{ is a Carmichael Sylow } p\text{-pseudoprime} < 10^{16}\}.$$

TABLE 4. The functions  $f_1(p_j)$  and  $f_2(p_j)$ 

$j$	2	3	4	5	6	7	8	...	100
$p_j$	3	5	7	11	13	17	19	...	541
$f_1(p_j)$	245288	215713	168856	100071	77178	55109	36363	...	630
$f_2(p_j)$	504	6168	10145	12130	11217	10239	9755	...	464

TABLE 5. List of all 3-fold Carmichael Sylow pseudoprimes  $< 10^{16}$ 

number $n$	factorization of $n$	factorization of $n - 1$	the set $P(n)$
1592075340241	$23 \cdot 89 \cdot 12959 \cdot 60017$	$2^4 \cdot 3 \cdot 5 \cdot 7 \cdot 11^2 \cdot 19 \cdot 31 \cdot 13297$	$\{3, 5, 7, 13297\}$
71370389440481	$1913 \cdot 7649 \cdot 4877513$	$2^5 \cdot 5 \cdot 13 \cdot 167 \cdot 239 \cdot 337 \cdot 2551$	$\{5, 13, 167, 337\}$
235549892165281	$353 \cdot 1013 \cdot 15137 \cdot 43517$	$2^5 \cdot 3 \cdot 5 \cdot 7 \cdot 11^2 \cdot 23 \cdot 43 \cdot 479 \cdot 1223$	$\{3, 5, 7, 479, 1223\}$

After checking all the 246683 Carmichael numbers  $< 10^{16}$  computed by Pinch [9], we obtain values of the functions  $f_1(p_j)$  and  $f_2(p_j)$  listed in Table 4.

We also find all 566 numbers which are 1-fold Carmichael Sylow pseudoprimes  $< 10^{16}$ . Twenty-three of the 566 numbers are 2-fold Carmichael Sylow pseudoprimes; three of the 23 numbers, listed in Table 5, are 3-fold Carmichael Sylow pseudoprimes, where the set

$$P(n) = \{\text{odd prime } p \mid n - 1 : n \text{ is a Carmichael Sylow } p\text{-pseudoprime}\}.$$

*Remark 4.1.* It is clear that Browkin's observation with  $p$  odd is not suitable for detecting compositeness of  $k$ -fold Carmichael Sylow pseudoprimes. Alford, Granville and Pomerance [2] have proved that there are infinitely many Carmichael numbers. Table 5 suggests that, for any  $k \geq 1$ , there would exist (infinitely many)  $k$ -fold Carmichael Sylow pseudoprimes.

## 5. SYLOW UNIFORM PSEUDOPRIMES

In this section, we will exhibit examples  $n$  which are Sylow  $p$ -pseudoprimes to the first  $k$  prime bases for almost all prime divisors  $p$  of  $n - 1$ .

**Definition 5.1.** A positive odd composite  $n$  is called a *Sylow uniform pseudoprime to bases*  $b_1, \dots, b_k$ , or a *Syl-upsp*( $b_1, \dots, b_k$ ) for short, if it is a  $\text{Syl}_p\text{-psp}(b_1, \dots, b_k)$  for all the first  $\omega(n - 1) - 1$  small prime factors  $p$  of  $n - 1$ , where  $\omega(n - 1)$  is the number of distinct prime factors of  $n - 1$ .

We have checked all the 52593  $\text{spsp}(2, 3)$ 's  $< 10^{16}$  and found all the 17  $\text{Syl-upsp}(2, 3, 5)$ 's  $< 10^{16}$  listed in Table 6.

We have also checked all the 44134  $\text{K3-spsp}(2, 3, 5, 7, 11)$ 's  $< 10^{24}$  and found seven  $\text{Syl-upsp}(2, 3, 5, 7, 11)$ 's  $n < 10^{24}$  listed in Table 7, where  $d = \omega(n - 1) - 1$  and  $n = q_1 \cdot q_2$  with  $q_2 - 1 = 3(q_1 - 1)$ .

*Remark 5.1.* Tables 6 and 7 suggest that, for any  $k \geq 1$ , there would exist (infinitely many) Sylow uniform pseudoprimes to the first  $k$  prime bases. However, it is not easy to check whether  $n$  is a Sylow uniform pseudoprime when  $n$  is large, since it is not an easy task to find the complete factorization of  $n - 1$  for large  $n$ .

6. COMPARISONS

Let  $n$  be an odd positive composite integer. Let  $b_k$  be the  $k$ th prime and let  $p_j$  be the  $j$ th smallest prime factor of  $n - 1$ . If  $n$  is an spsp( $b_1, \dots, b_t$ ) but not an spsp( $b_{t+1}$ ), then we define

$$T_1(n) = t + 1,$$

i.e.,  $T_1(n)$  is the number of Miller tests (1.2) used for detecting the compositeness of  $n$ . Define

$$T_2(n) = \begin{cases} 3t + 1, & \text{if } n \in \text{Syl}_p(2, 3, 5) \text{ for all } p \in \{p_1, \dots, p_t\} \text{ but } n \notin \text{Syl}_{p_{t+1}}(2); \\ 3t + 2, & \text{if } n \in \text{Syl}_p(2, 3, 5) \text{ for all } p \in \{p_1, \dots, p_t\} \text{ and } n \in \text{Syl}_{p_{t+1}}(2) \\ & \text{but } n \notin \text{Syl}_{p_{t+1}}(2, 3); \\ 3t + 3, & \text{if } n \in \text{Syl}_p(2, 3, 5) \text{ for all } p \in \{p_1, \dots, p_t\} \text{ and } n \in \text{Syl}_{p_{t+1}}(2, 3) \\ & \text{but } n \notin \text{Syl}_{p_{t+1}}(2, 3, 5). \end{cases}$$

**Example 6.1.** Let

$$N = 7 \cdot 83218 \cdot 67980 \cdot 76961 = 51095293 \cdot 153285877.$$

Then

$$N - 1 = 2^5 \cdot 3 \cdot 5 \cdot 11 \cdot 29 \cdot 41 \cdot 71 \cdot 293 \cdot 59971.$$

Since  $N \in \text{spsp}(2, 3, 5)$  but  $N \notin \text{spsp}(7)$ , we have  $T_1(N) = 4$ . Since

$$N \in \text{Syl}_p\text{-psp}(2, 3, 5) \text{ for all } p \in \{2, 3, 5, 11, 29, 41\}$$

and  $N \in \text{Syl}_{41}\text{-psp}(2)$ , but  $N \notin \text{Syl}_{41}\text{-psp}(2, 3)$ , we have  $T_2(N) = 20$ .

Now suppose Alice uses Miller tests (1.2) (Procedure A) and Bob uses Browkin's observation (Procedure B) to detect the compositeness of an odd positive composite number  $n$ , although Procedure B is not explicitly given in [5].

**Procedure A;** {Input an odd positive composite number  $n$ , output  $T_1(n)$ }

Begin  $k \leftarrow 0$ ;

Repeat  $k \leftarrow k + 1$  Until  $n$  is not an  $\text{spsp}(b_k)$  (i.e., (1.2) is not satisfied for  $b_k$ );

$T_1(n) \leftarrow k$

End.

**Procedure B;** {Input an odd positive composite number  $n$ ; output  $T_2(n)$  and a message if it fails on detecting the compositeness of  $n$ }

Begin Using trial division to find all prime factors less than, say 1000, of  $n - 1$ :

$2 = p_1 < p_2 < \dots < p_r < 1000$ ;

$j \leftarrow 0$ ;  $T_2(n) \leftarrow 0$ ;

Repeat  $j \leftarrow j + 1$ ;  $k \leftarrow 0$ ;

repeat  $k \leftarrow k + 1$ ;  $T_2(n) \leftarrow T_2(n) + 1$ ;

If (1.4) does not hold for  $p = p_j$  Then

begin Output  $T_2(n), p_j$  and  $b_k$ ; exit end

until  $k = 3$

Until  $j = r$ ;

Output the message "The procedure fails on detecting the compositeness of  $n$ ,"

"since  $n \in \text{Syl}_p(2, 3, 5)$  for all prime factors  $p < 1000$  of  $n - 1$ ,"

"increase the number of bases and try once again"

End.

*Remark 6.1.* Then  $p$  is small, the arithmetic labor for checking (1.4) is almost the same as (in fact a little more than) that for doing  $k$  Miller tests, since it is dominated by the number of computations of (1.3). So, if  $T_1(n) = T_2(n)$ , then one may take into account that both Procedures A and B terminate at the same time.

Let  $\mathcal{S}$  be a set of some odd composites, and let  $g$  be an integer. Define

$$\Delta(\mathcal{S}, g) = \#\{n \in \mathcal{S} : T_2(n) - T_1(n) = g\},$$

$F(\mathcal{S}) = \#\{n \in \mathcal{S} : \text{Procedure B fails on detecting the compositeness of } n\}$ ,

and for  $i = 1$  and  $2$ , define

$$T_i(\mathcal{S}) = \sum_{n \in \mathcal{S}} T_i(n).$$

Let  $\mathcal{S}_1$  be the set of all  $\text{spsp}(2, 3, 5)$ 's  $< 10^{12}$ , and let  $\mathcal{S}_2$  be the set of all  $\text{spsp}(2, 3, 5)$ 's  $< 10^{16}$ . The values of  $T_i(\mathcal{S}_j)$ ,  $F(\mathcal{S}_j)$  and  $\Delta(\mathcal{S}_j, g)$  are listed in Table 8.

TABLE 8. List of  $\mathcal{T}_i(\mathcal{S}_j)$ ,  $F(\mathcal{S}_j)$  and  $\Delta(\mathcal{S}_j, g)$

$j$	$\#\mathcal{S}_j$	$\mathcal{T}_1(\mathcal{S}_j)$	$\mathcal{T}_2(\mathcal{S}_j)$	$F(\mathcal{S}_j)$
1	101	413	443	0
2	4603	19139	20942	28

  

$g$	-4	-3	-2	-1	0	1	2	3	4	5...12	13	14	16
$\Delta(\mathcal{S}_1, g)$	0	0	8	15	38	26	10	1	3	0	0	0	0
$\Delta(\mathcal{S}_2, g)$	7	29	379	611	1673	1302	352	50	112	82	3	2	1

TABLE 9. Additional 11  $\text{spsp}(2, 3, 5)$ 's  $< 10^{16}$ , the compositeness of which were not detected by Bob using Procedure B

number $n$	factorization of $n$	factorization of $n - 1$
85755911820409	4141399 · 20706991	$2^3 \cdot 3^2 \cdot 690233 \cdot 1725583$
523892725527121	8651117 · 60557813	$2^4 \cdot 3 \cdot 5 \cdot 41 \cdot 103 \cdot 239 \cdot 1213 \cdot 1783$
674135799997687	12982063 · 51928249	$2 \cdot 3 \cdot 13 \cdot 8642766666637$
707828998720421	10861469 · 65168809	$2^2 \cdot 5 \cdot 35391449936021$
876990254595451	14807011 · 59228041	$2 \cdot 3 \cdot 5^2 \cdot 493567 \cdot 11845609$
1085151991776847	16470823 · 65883289	$2 \cdot 3 \cdot 7^2 \cdot 23 \cdot 53 \cdot 1103 \cdot 1361 \cdot 2017$
2193553913077421	19120469 · 114722809	$2^2 \cdot 5 \cdot 109677695653871$
4253769090466087	32610463 · 130441849	$2 \cdot 3 \cdot 708961515077681$
7365160150662949	27138829 · 271388281	$2^2 \cdot 3 \cdot 31 \cdot 19798817609309$
7837087315919287	44263663 · 177054649	$2 \cdot 3 \cdot 1306181219319881$
9988504355646277	49971253 · 199885009	$2^2 \cdot 3 \cdot 832375362970523$

From Table 8 we see that  $\mathcal{T}_2(\mathcal{S}_j) > \mathcal{T}_1(\mathcal{S}_j)$ , which means that Procedure B runs slower in the average than Procedure A for detecting the compositeness of the 101  $\text{spsp}(2, 3, 5)$ 's  $< 10^{12}$  and of the 4603  $\text{spsp}(2, 3, 5)$ 's  $< 10^{16}$ . Moreover, Procedure B fails on detecting the compositeness of 28  $\text{spsp}(2, 3, 5)$ 's  $< 10^{16}$ , 17 of which are the  $\text{Syl}_p\text{-upsp}(2, 3, 5)$ 's listed in Table 6, and the other 11 numbers  $n$  of which are  $\text{Syl}_p\text{-psp}(2, 3, 5)$ 's for all prime divisors  $p < 1000$  of  $n - 1$ , listed in Table 9. Of course, the compositeness of these 28  $\text{spsp}(2, 3, 5)$ 's could be detected by Bob using Procedure B, if he checked more than three bases for each prime  $p$ . But it is a difficult problem for Browkin's observation to decide how many bases should be checked for each prime  $p$ , due to the existence of a  $k$ -fold Carmichael Sylow pseudoprime and Sylow uniform pseudoprimes. However, using Miller tests (Procedure A), Alice may not only easily detect the compositeness of all odd composites, but also can give swift primality proofs for primes to given bounds [11, 7, 14, 17, 16, 15].

*Remark 6.2.* There are six numbers  $n$  in Table 9, for each of which  $n - 1$  has only two small prime divisors.

ACKNOWLEDGMENT

I thank the referee for helpful comments that improved the presentation of the paper.
