A GILBERT-VARSHAMOV TYPE BOUND FOR EUCLIDEAN PACKINGS

GABRIELE NEBE AND CHAOPING XING

Abstract. This paper develops a method to obtain a Gilbert-Varshamov type bound for dense packings in the Euclidean spaces using suitable lattices. For the Leech lattice the obtained bounds are quite reasonable for large dimensions, better than the Minkowski-Hlawka bound, but not as good as the lower bound given by Keith Ball in 1992.

1. Introduction

It is a classical problem to find dense sphere packings in Euclidean space; see for instance [2, 3, 4, 7] for an introduction to this topic.

For a real $b > 0$, let $A_b^m$ be the ball of radius $b$ in $\mathbb{R}^m$ defined by

$$ A_b^m := \{ x := (x_1, \ldots, x_m) \in \mathbb{R}^m : \|x\|^2 := \sum_{i=1}^{m} x_i^2 \leq b^2 \}. $$

Then the volume of $A_b^m$ is equal to $V_m \cdot b^m$, where $V_m = \frac{\pi^{m/2}}{\Gamma(m/2+1)}$ denotes the volume of a unit ball in $\mathbb{R}^m$. A packing in $\mathbb{R}^m$ is a set $\mathcal{P}$ of points in $\mathbb{R}^m$ such that the Euclidean distance of $\mathcal{P}$,

$$ d(\mathcal{P}) := \inf_{u,v \in \mathcal{P}, u \neq v} d(u,v), $$

is positive. It is clear that all balls with radius $d(\mathcal{P})/2$ and centers being points of $\mathcal{P}$ are not overlapping. Let $U(\mathcal{P})$ be the union of all such balls, i.e.,

$$ U(\mathcal{P}) = \{ x \in \mathbb{R}^m : \exists u \in \mathcal{P} \text{ such that } d(x,u) \leq d(\mathcal{P})/2 \}. $$

Then the density of $\mathcal{P}$ is defined by

$$ \Delta(\mathcal{P}) = \limsup_{b \to \infty} \frac{\text{vol}(U(\mathcal{P}) \cap A_b^m)}{\text{vol}(A_b^m)}, $$

where $\text{vol}(\mathcal{T})$ denotes the volume of a subset $\mathcal{T}$ in $\mathbb{R}^m$. It is clear that $\Delta(\mathcal{P}) \leq 1$. We are interested in dense packings, i.e., we want to find a packing with density close to the quantity

$$ \Delta_m := \limsup_{\mathcal{P}} \Delta(\mathcal{P}), $$

where \( P \) is extended over all packings in \( \mathbb{R}^m \). Sometimes, it is more convenient to convert \( \Delta_m \) into the center density which is defined by

\[
\delta_m := \frac{\Delta_m}{V_m}.
\]

The Gilbert-Varshamov (G-V, for short) bound is a benchmark for good codes in coding theory. The idea involved in the G-V bound can be employed for many other problems. In this paper, we use the idea to construct dense packings in \( \mathbb{R}^m \) by choosing a subset of certain lattice points. It turns out that the obtained G-V type bound is quite reasonable. For the orthogonal sum of copies of the Leech lattice, it is better than the Minkowski-Hlawka bound, but not as good as the lower bound given in [1]. Up to now no sphere packings have been described that beat our bounds. A table for densities for large dimensions divisible by 720 is given in this paper.

2. Gilbert-Varshamov Type Bound

In this section we fix a lattice \( L \) of dimension \( m \) in Euclidean space \( \mathbb{R}^m \) such that all norms in \( L \) are integers, i.e., \( ||c||^2 \in \mathbb{Z} \) for all \( c \in L \). For a point \( c \in L \) and an integer \( k > 0 \), define the ball \( B_{L,k}(c) \) to be the set consisting of points in \( L \) with Euclidean distance from \( c \) at most \( \sqrt{k} \), i.e.,

\[
B_{L,k}(c) := \{ b \in L : ||b - c||^2 \leq k \}.
\]

It is clear that \( B_{L,k}(c) \) is a finite set and its cardinality, denoted by \( B_{L,k} \), is independent of its center \( c \). In fact, we have

\[
B_{L,k} = 1 + \sum_{i=1}^{k} S_{L,i},
\]

where \( S_{L,i} \) is the number of lattice points of norm \( i \) in \( L \).

One important invariant of \( L \) is its discriminant \( D \), defined as the determinant of a Gram matrix of \( L \), or equivalently as the square of the volume of a fundamental domain of \( L \) in \( \mathbb{R}^m \) (see [3]). It measures the number of lattice points contained in a unit ball.

**Lemma 2.1.** Let \( L \) be a lattice in \( \mathbb{R}^m \) with discriminant \( D \). Then

\[
\lim_{b \to \infty} \frac{B_{L,b}}{V_m b^{m/2}} = \frac{1}{\sqrt{D}},
\]

where \( V_m \) is the volume of the unit ball in \( \mathbb{R}^m \).

**Proof.** Clearly, \( \sqrt{D} \) is the volume of the Dirichlet domain

\[
D_L = \{ x \in \mathbb{R}^m : ||x|| < ||x - \ell|| \; \forall 0 \neq \ell \in L \}
\]

around 0. For a fixed \( b \), the \( B_{L,b} \) translates \( \ell + D_L \) with \( \ell \in B_{L,b}(0) \) tile a subset of volume \( B_{L,b}\sqrt{D} \) of \( \mathbb{R}^m \), which tends to be the ball around 0 with radius \( \sqrt{b} \) when \( b \) tends to infinity. \( \square \)

**Theorem 2.2.** Let \( L \subseteq \mathbb{R}^m \) be a lattice of discriminant \( D \), such that all norms in \( L \) are integral. Then for any integer \( r \geq 1 \), one has

\[
\Delta_m \geq \frac{1}{\sqrt{D}} \times \frac{1}{B_{L,r}} \times \left( \frac{\sqrt{r+1}}{2} \right)^m \times V_m,
\]

License or copyright restrictions may apply to redistribution; see http://www.ams.org/journal-terms-of-use
hence
\begin{equation}
\delta_m \geq \frac{1}{2m} \frac{\max_{r \geq 1} \left( \frac{(r+1)^{m/2}}{B_{L,r}} \right)}{\sqrt{D}}.
\end{equation}

Proof. For a sufficiently large integer $b > 0$ choose an arbitrary point $c_1$ from $B_{L,b}(0)$. Pick up a point $c_2$ from $B_{L,b}(0) \setminus B_{L,r}(c_1)$. Then pick up a point $c_3$ from $B_{L,b}(0) \setminus B_{L,r}(c_1) \cup B_{L,r}(c_2)$.

This procedure constructs a subset $C := \{c_1, \ldots, c_{M+1}\}$ of $B_{L,b}(0)$ with
\begin{equation*}
M := \left\lceil \frac{B_{L,b} - 1}{B_{L,r}} \right\rceil
\end{equation*}
such that
\begin{equation*}
c_i \in B_{L,b}(0) \setminus \bigcup_{j=1}^{i-1} B_{L,r}(c_j)
\end{equation*}
for any $1 \leq i \leq M + 1$. This is because the set $B_{L,b}(0) \setminus \bigcup_{j=1}^{i-1} B_{L,r}(c_j)$ is not empty due to the fact that
\begin{equation*}
|B_{L,b}(0) \setminus \bigcup_{j=1}^{i-1} B_{L,r}(c_j)| \geq |B_{L,b}(0)| - \left| \bigcup_{j=1}^{i-1} B_{L,r}(c_j) \right| \geq B_{L,b} - M \cdot B_{L,r} > 0.
\end{equation*}

Since norms in $L$ are integral and $||c_i - c_j||^2 > r$ for $i \neq j$ by construction, any two distinct points in the set $C$ have Euclidean distance at least $\sqrt{r+1}$. Hence the balls around distinct $c_j$ with radius $\sqrt{r+1/2}$ are disjoint. When $b$ tends to $\infty$ this yields
\begin{equation*}
\Delta_m \geq \lim_{b \to \infty} \frac{M}{V_m b^{m/2}} \times \left( \frac{\sqrt{r+1}}{2} \right)^m \times V_m
\end{equation*}
\begin{equation*}
= \lim_{b \to \infty} \frac{B_{L,b}}{V_m b^{m/2}} \times \frac{1}{B_{L,r}} \times \left( \frac{\sqrt{r+1}}{2} \right)^m \times V_m
\end{equation*}
\begin{equation*}
= \frac{1}{\sqrt{D}} \times \frac{1}{B_{L,r}} \times \left( \frac{\sqrt{r+1}}{2} \right)^m \times V_m.
\end{equation*}

The desired result follows. \hfill \Box

Remark 2.3. As $r$ tends to infinity, the right hand side of the inequality \eqref{eq:2.2} tends to $\frac{1}{2m} \log_2(\Delta_m)$ yielding asymptotically the same bound as the Minkowski-Hlawka bound, $\frac{1}{m} \log_2(\Delta_m) \geq -1$. However, for smaller values of $r$ the right hand side may be bigger, which yields a slight improvement of this bound.

3. Numerical Results

In applications one usually chooses orthogonally decomposable lattices
\begin{equation*}
L = L_1^{n_1} \perp L_2^{n_2} \perp \ldots \perp L_s^{n_s} \subseteq \mathbb{R}^m
\end{equation*}
of dimension $m = \sum_{i=1}^s n_i \dim(L_i)$ and discriminant $D = \prod_{i=1}^s D_i^{n_i}$, where $D_i$ denotes the discriminant of $L_i$. We obtained good results by choosing
\begin{equation*}
L = \frac{1}{\sqrt{2}} A_{24}^{n_1} \perp \frac{1}{\sqrt{2}} A_2^{n_2} \perp \mathbb{Z}^{n_3}
\end{equation*}
with $m = 24n_1 + 2n_2 + n_3$, $0 \leq n_2 \leq 11$, $0 \leq n_3 \leq 1$ where $A_{24} \subseteq \mathbb{R}^{24}$ denotes the Leech lattice and $A_2$ the 2-dimensional hexagonal lattice. Then $D_1 = 2^{-24}$,
$D_2 = \frac{3}{4}$ and $D_3 = 1$, and so $\log_2(\frac{1}{\sqrt{3}}) = 12n_1 + n_2\alpha$ with $\alpha = (1 - \log_2(\sqrt{3}))$ and hence $\log_2(\delta_m) \geq b_0(m)$ where

$$b_0(24n_1 + 2n_2 + n_3)$$

$$= 12n_1 + \alpha n_2 + \max_{r \geq 1} \left((12n_1 + n_2 + \frac{n_3}{2}) \log_2 \left(\frac{r + 1}{4}\right) - \log_2(B_{L,r})\right)$$

(3.1)

$$\geq b_0(24n_1 + 2n_2 + n_3, r_0)$$

$$= 12n_1 + \alpha n_2 + (12n_1 + n_2 + \frac{n_3}{2}) \log_2 \left(\frac{r_0 + 1}{4}\right) - \log_2(B_{L,r_0})$$

for any integer $r_0 \geq 1$. The following table lists a few examples (truncated to the second decimal place).

</tbody>
</table>
and hence
\[ \log_2(\delta_m) \geq \text{ball}(m) = mh(m) + \log_2(m - 1) \]

with
\[ mh(m) = \log_2(\zeta(m)) + \log_2((m/2)! + 1 - m + (m/2) \log_2(\pi)). \]

For dimensions \( m = 720n \) we compare our bounds \( b_1(m, r_1) \) and \( b_2(m, r_2) \) obtained by taking \( L = \frac{1}{\sqrt{2}} \Lambda_{24}^{30n} \), respectively \( L = \frac{1}{\sqrt{2}} \Lambda_{72}^{10n} \) (for some putative extremal even unimodular lattice \( \Lambda_2 \)) and choosing suitable integers \( r_1, r_2 \geq 1 \) to these two bounds. This shows that our lower bounds are better than the Minkowski-Hlawka bound, but not as good as the ones obtained by Keith Ball. Our construction is explicitly described, though it is not of polynomial-time, while the other two bounds, by Minkowski-Hlawka and Ball, are nonconstructive.

The results (rounded to 10 decimal places) were calculated with MAGMA [1] using the modular forms package.
\begin{tabular}{|c|c|c|c|c|c|}
