GLOBAL SMOOTH SOLUTION CURVES
USING RIGOROUS BRANCH FOLLOWING

JAN BOUWE VAN DEN BERG, JEAN-PHILIPPE LESSARD,
AND KONSTANTIN MISCHAIKOW

ABSTRACT. In this paper, we present a new method for rigorously computing
smooth branches of zeros of nonlinear operators \( f : \mathbb{R}^l \times B_1 \rightarrow \mathbb{R}^l \times B_2 \), where
\( B_1 \) and \( B_2 \) are Banach spaces. The method is first introduced for parameter
continuation and then generalized to pseudo-arclength continuation. Examples
in the context of ordinary, partial and delay differential equations are given.

1. INTRODUCTION

Finding solutions of a nonlinear functional differential equation
\[
\mathcal{G}(p, u) = 0,
\]
where \( p \) is a set of parameters, is central in mathematics. In particular, when \( \mathcal{G} \)
takes the form of a partial differential equation or a delay equation, finding explicit
solutions becomes a real challenge due to the nonlinearity of \( \mathcal{G} \) and the fact that
the state space is infinite dimensional.

Several computer-assisted approaches rigorously solving systems of nonlinear
equations have been proposed since the early 1990s \([2, 4, 5, 7, 10, 11, 12, 13, 14, 15, 17, 18]\). A combination of topological methods (Banach fixed point theorem, Conley
index theory), a priori analytic estimates and use of interval arithmetic have led
to new theorems about the existence of solutions. In early works, such as \([17, 18]\),
the proofs of existence were done for fixed parameters. In \([5, 7]\), these arguments
were put in a context of continuation where a premium was placed on minimizing
computational cost; but the focus remained on discrete parameter values only. This
method was referred to as validated continuation. In \([4, 10]\), continuous branches
of solution curves were obtained in the context of a predictor-corrector algorithm.
The idea was to work directly with small intervals of parameters (using interval
arithmetic) and then draw conclusions about solution branches for these intervals
of parameters. However, the computational cost of such methods is high, since
trivial predictors were used, leading to very small step sizes in the parameter. In \([1]\),
validated continuation was adapted to prove the existence of piecewise continuous
solution curves of \([1]\). At each step of the algorithm, first order predictors were used

to prove the existence of small continuous solutions curves, allowing significantly larger step sizes. With this in mind, we now aim to develop a method that will allow us to rigorously obtain the existence of global smooth solution curves in the context of both parameter and pseudo-arclength continuation.

Before proceeding, it is worth mentioning that this method might as well be applied to finite dimensional systems. However, the motivation for applying rigorous numerical techniques to such a problem is less appealing, as the confidence in getting reliable outputs from classical numerical methods is high and since the main source of error is often due to round-off. In the context of infinite dimensional problems, the numerical methods must be applied to some finite dimensional approximation, which raises questions concerning the validity of the output. With this in mind, we develop a method that provides an internal check of consistency on the dimension of truncation from the infinite to finite dimensional problem, hence delivering rigorous mathematical proofs.

When looking for solutions of (1) with a periodic profile, one may apply a Fourier transformation to the a priori unknown solution $u$ and then solve for the Fourier coefficients. This transforms (1) into an equivalent problem in Fourier space. We will turn to concrete examples quickly, where we also specify the parameters and spaces involved, but we first introduce the general setting and notation. Denote by $g : \mathbb{R}^{l_1} \times B_1 \to B_2$ the Fourier transformation of $G$, where $\mathbb{R}^{l_1}$ is the parameter space and $B_1, B_2$ are Banach spaces. Sometimes we will be interested in finding solutions of $g = 0$ satisfying additional conditions (see Examples 1 and 2 below). An extra set of $l_2$ equations will then ensure that the additional conditions are satisfied, i.e., $h = 0$ with $h : \mathbb{R}^{l_2} \times B_1 \to \mathbb{R}^{l_2}$. Hence, consider the infinite dimensional system of equations

$$\mathcal{F} : \mathbb{R}^{l_1} \times B_1 \to \mathbb{R}^{l_2} \times B_2 : (p, \xi) \mapsto \mathcal{F}(p, \xi) = (h(p, \xi), g(p, \xi)) = 0,$$

where $p = (p_1, \ldots, p_{l_1}) \in \mathbb{R}^{l_1}$ are the original parameters of (1) and $\xi$ consists of the Fourier coefficients of $u$. To be more specific, we denote these by $\xi = (\xi_k)_{k=0}^\infty$ with, in general, $\xi_k \in \mathbb{R}^n$, $n \geq 1$ (see below for examples where $n = 1, 2$; one may also think of systems of equations and higher dimensional spatial settings leading to larger $n$). In this paper, we do not deal with the details of the equivalence (for periodic solutions) of (1) and (2), which will be context dependent. Let us remark that although in the present paper we restrict our attention to periodic solutions, extensions to nonperiodic (boundary value) problems are possible within this setting.

Since the periodic solutions of (1) we are looking for are reasonably smooth, we choose our Banach spaces such that the Fourier coefficients of $u$ decay quickly. There are of course many possibilities. We only deal with one popular choice, used in [1, 4, 5, 6, 7], mostly in the context of validated continuation. We choose weight functions ($q > 0$)

$$\omega^q_k = \begin{cases} 1, & k = 0, \\ q^k, & k \geq 1, \end{cases}$$

which are used to define the norm

$$\|\xi\|_q = \sup_{k \geq 0} \omega^q_k |\xi_k|_{\infty}$$
and the Banach space
\[ \Omega^q = \{ \xi, \|\xi\|_q < \infty \}, \]
consisting of sequences with algebraically decaying tails. We finally let \( B_1 = \Omega^{q_1} \) and \( B_2 = \Omega^{q_2} \). Throughout we assume that \( \mathcal{F} \) is a \( C^1 \) function.

**Example 1.** Consider the problem of computing periodic solutions (with a special symmetry) of the fourth order Swift-Hohenberg ordinary differential equation
\[ -u''' - \nu u'' + u - u^3 = 0, \quad \nu \in \mathbb{R}. \]
This ordinary differential equation has a conserved quantity (first integral), called the energy, which is given by
\[ E = u''' u' - \frac{1}{2} u''^2 + \frac{\nu}{2} u'^2 - \frac{1}{4}(u^2 - 1)^2. \]
We restrict our attention to finding periodic solutions at the zero energy level \( E = 0 \).

Plugging the cosine Fourier expansion
\[ u(y) = \xi_0 + 2 \sum_{k \geq 1} \xi_k \cos kLy \]
into (6), the problem \( g = (g_k)_{k \geq 0} = 0 \), where
\[ g_k \overset{\text{def}}{=} [1 + \nu L^2 k^2 - L^4 k^4] \xi_k - \sum_{k_1 + k_2 + k_3 = k} \xi_{k_1} \xi_{k_2} \xi_{k_3}, \quad k \geq 0, \]
corresponds to finding periodic solutions \( u \) of (6); see \[1\]. Here \( p = (p_1, p_2) \in \mathbb{R}^2 \), where \( p_1 = \nu \) and \( p_2 = L \) is the frequency of \( u \) \((\frac{2\pi}{L} \) is its period). The extra equation
\[ h \overset{\text{def}}{=} -2L^2 \sum_{l=1}^{\infty} l^2 \xi_l - \frac{1}{\sqrt{2}} \left[ \xi_0 + 2 \sum_{l=1}^{\infty} \xi_l \right]^2 + \frac{1}{\sqrt{2}} = 0 \]
is added in order to ensure that \( E = 0 \) (one evaluates the energy at \( y = 0 \), where \( u' = 0 \)). Letting \( \mathcal{F} = (h, g) \), the problem \( \mathcal{F}(p, \xi) = 0 \) is considered, with \( \mathcal{F} : \mathbb{R}^2 \times \Omega^q \to \mathbb{R} \times \Omega^{q-4}, q > 3 \); see also Section \[12\].

**Example 2.** Consider the problem of finding periodic solutions of the so-called Wright’s delay equation
\[ y'(t) = -\alpha g(t-1)[1 + y(t)], \quad \alpha > \frac{\pi}{2}, \]
considered in \[16\]. Plugging the Fourier expansion
\[ y(t) = \xi_{0,1} + 2 \sum_{k=1}^{\infty} [\xi_{k,1} \cos kL t - \xi_{k,2} \sin kL t] \]
into (8) and letting \( \xi_k \overset{\text{def}}{=} (\xi_{k,1}, \xi_{k,2}) \in \mathbb{R}^2 \) (with \( \xi_{0,2} = 0 \)), consider
\[ g_k \overset{\text{def}}{=} R_k \left( \frac{\xi_{k,1}}{\xi_{k,2}} \right) + \alpha \sum_{k_1 + k_2 = k} \Theta_{k_1} \left( \xi_{k_1,1,1} \xi_{k_2,1} - \xi_{k_1,2} \xi_{k_2,2} \xi_{k_1,1} \xi_{k_2,1} + \xi_{k_1,1} \xi_{k_2,2} \right), \quad k \geq 0, \]
where
\[ R_k = \begin{pmatrix} \alpha \cos kL & -kL + \alpha \sin kL \\ kL - \alpha \sin kL & \alpha \cos kL \end{pmatrix} \quad \text{and} \quad \Theta_{k_1} = \begin{pmatrix} \cos k_1 L & \sin k_1 L \\ -\sin k_1 L & \cos k_1 L \end{pmatrix}. \]
Solving \( g = (g_k)_{k \geq 0} = 0 \) corresponds to finding periodic solutions of (8); see [9]. In order to eliminate arbitrary shifts of the periodic solution \( y \), the normalizing condition \( y(0) = 0 \) is imposed. Hence,

\[
h \overset{\text{def}}{=} y(0) = \xi_{0,1} + 2 \sum_{k=1}^{\infty} \xi_{k,1} = 0
\]

is appended to \( g = 0 \). Letting \( \mathcal{F} = (h, g) \) and \( p = (\alpha, L) \in \mathbb{R}^2 \), the problem \( \mathcal{F}(p, \xi) = 0 \) is considered, with \( \mathcal{F} : \mathbb{R}^2 \times \Omega^q \to \mathbb{R} \times \Omega^{q-1}, q \geq 2 \).

**Example 3.** Consider the problem of looking for stationary solutions of nonlinear partial differential equations of the form

\[
(u_t = \mathcal{L}(p, u) + \sum_{j=2}^{P} c_j(p)uj \quad \text{in } D = \prod_{l=1}^{N} \left[0, \frac{2\pi}{L_l}\right],
\]

defined on \( N \)-dimensional rectangular spatial domains, where \( \mathcal{L} \) is a linear differential operator in \( u \). In particular, consider the two-dimensional problem \( N = 2 \), \( \mathcal{L}(u) = (\nu - (1 + \Delta)^2)u, P = 3, c_2 = 0, c_3 = -1 \) with periodic boundary conditions; see [6]. More precisely, consider

\[
\begin{align*}
u u - (1 + \Delta)^2 u - u^3 &= 0, \quad \text{in } D = \left[0, \frac{2\pi}{L_1}\right] \times \left[0, \frac{2\pi}{L_2}\right], \\
\mathcal{F}(x, y, t) &= u(x, y, t) - u(x + \frac{2\pi}{L_1}, y, t), \quad \mathcal{F}(x, y, t) = u(x, y + \frac{2\pi}{L_2}, t), \\
\mathcal{F}(x, y, t) &= u(-x, y, t) - u(x, -y, t) = u(-x, -y, t).
\end{align*}
\]

Plugging the expansion of the time independent a priori unknown solution

\[
u u(x, y) = \sum_{k_1, k_2 \in \mathbb{Z}} c_{k_1, k_2} e^{ik_1 L_1 x} e^{ik_2 L_2 y}
\]

into (10), we need to solve

\[
g_{i,j}(\nu, \xi) \overset{\text{def}}{=} \mu_{i,j}(\nu) \xi_{i,j} - \sum_{i_1, i_2, j_1, j_2, k_1, k_2 \in \mathbb{Z}} \xi_{i_1,j_1} \xi_{i_2,j_2} \xi_{i_3,j_3} = 0, \quad i, j \geq 0,
\]

where \( \xi_{i,j} \) is the real part of \( c_{i,j} = (\xi_{i,j})_{i,j \geq 0} \), \( \xi_{-i,-j} = \xi_{i,j} \), \( \xi_{-i,j} = \xi_{-i,-j} = \xi_{i,j} \), and \( \mu_{i,j} = \nu - \left[1 - (t^2 L_1^2 + j^2 L_2^2)^2\right] \). Letting \( \mathcal{F} = (g_{i,j})_{i,j \geq 0} \), solving \( \mathcal{F}(\nu, \xi) = 0 \) corresponds to finding solutions of (10).

### 1.1. Parameter continuation.

We want to develop a computational method to rigorously continue the zeros of \( \mathcal{F} : \mathbb{R}^l \times \Omega^q \to \mathbb{R}^l \times \Omega^q \), as we move one of the parameters of \( p \), say \( p_1 \). We introduce only the main ideas here, and discuss the method in detail in Section 2. Fixing the parameters \( p_2, \ldots, p_l \) and considering \( \nu \overset{\text{def}}{=} p_1 \) as the continuation parameter, we define the infinite dimensional vector of variables \( x = (p_2, \ldots, p_l, \xi) \) and the new map

\[
f : \mathbb{R} \times \left[\mathbb{R}^l \times \Omega^q\right] \to \mathbb{R}^l \times \Omega^q : (\nu, x) \mapsto f(\nu, x).
\]

Under the assumption that \( D_x f(\nu, x) \) is nonsingular along the branch of zeros that we are computing, we vary the parameter \( \nu \). In this case, the implicit function theorem implies that the branch of zeros can be viewed globally as the graph of a function of the parameter \( \nu \). The idea is to transform the problem \( f(\nu, x) = 0 \)
into a fixed point equation and to apply the Banach fixed point theorem. Since we want develop this idea in a computational setting, consider a finite dimensional projection \( f^{(m)} \) of \( f \). First, using a Newton-like iterative scheme on \( f^{(m)} \), we compute an approximate zero \( \bar{x} \) of \( f^{(m)} \) at the parameter value \( \nu = \nu_0 \). Next, we compute a tangent vector \( \dot{x} \) such that \( D_x f(\nu_0, \bar{x}) \dot{x} + D_x f(\nu_0, \bar{x}) \approx 0 \). Using the vectors \( \bar{x} \) and \( \dot{x} \), we define the set of predictors by

\[
x_{\nu} = \bar{x} + \Delta_{\nu} \dot{x},
\]

where \( \Delta_{\nu} \) is small. Consider the Banach space \( \Phi = \mathbb{R}^{1-1} \times \Omega^q \) (with the induced product norm). We compute an approximate inverse \( A \) of the linear operator \( D_x f(\nu_0, \bar{x}) \). For \( \nu = \nu_0 + \Delta_{\nu} \), we define \( T_{\nu} : \Phi \to \Phi \) by

\[
T_{\nu}(x) = x - Af(\nu, x),
\]

and look for a fixed point of \( T_{\nu} \) using the Banach fixed point theorem. Note that \( A \) is injective to ensure that fixed points of \( T \) are in bijection with zeros of \( f \).

**Example 4.** For the problem introduced in Example 1 the approximate inverse \( A \) may be constructed as follows. Denote by \( D_x f^{(m)}(\nu_0, \bar{x}) \) the Jacobian matrix of the projection \( f^{(m)} \) at the approximate solution \( (\nu_0, \bar{x}) \), and let \( J_m \) be an approximate inverse of \( D_x f^{(m)}(\nu_0, \bar{x}) \), computed using an LU decomposition. Recalling (7), denote the linear part of \( g_k \) by \( \mu_k(\nu, \nu) = 1 + \nu L^2 k^2 - L^4 k^4 \). Now we define

\[
A \overset{\text{def}}{=} \begin{bmatrix}
J_m & 0 & 0 & 0 \\
0 & \mu_m(\bar{L}, \nu_0)^{-1} & 0 & 0 \\
0 & 0 & \mu_{m+1}(\bar{L}, \nu_0)^{-1} & 0 \\
0 & 0 & 0 & \mu_{m+2}(\bar{L}, \nu_0)^{-1} \\
\vdots & \vdots & \vdots & \ddots
\end{bmatrix},
\]

which acts as an approximate inverse of the linear operator \( D_x f(\nu_0, \bar{x}) \), provided of course that the projection dimension \( m \) is large enough. Note that \( A : \mathbb{R} \times \Omega^{q-4} \to \mathbb{R}^2 \times \Omega^q \).

The goal is to prove that there exists a ball \( B(r, \Delta_{\nu}) = x_{\nu} + B(r) \subset \Phi \) of radius \( r \) using norm (4), centered at \( x_{\nu} \), such that \( T_{\nu} \) maps the ball \( B(r, \Delta_{\nu}) \) into itself and acts as a contraction on \( B(r, \Delta_{\nu}) \), for small \( \Delta_{\nu} = \nu - \nu_0 \). To verify these conditions, we need to compute two bounds \( Y = Y(\Delta_{\nu}) \) and \( Z = Z(\Delta_{\nu}) \). In essence, \( Y \) measures how far the center \( x_{\nu} \) of \( B(r, \Delta_{\nu}) \) is mapped from itself (under \( T_{\nu} \)), whereas \( Z \) measures the contraction rate of (all components of) \( T_{\nu} \) on \( B(r, \Delta_{\nu}) \). The most computationally demanding part of the method is the construction of the bounds \( Y \) and \( Z \); see for instance Sections 3.2 and 3.3 in [1] or Section 6 in [5]. Their construction requires a combination of a priori analytic estimates (bounds on the truncation error terms) and rigorous computations involving interval arithmetic. Once the bounds \( Y \) and \( Z \) are computed, verifying that

\[
\|Y(\Delta_{\nu}) + Z(\nu, \Delta_{\nu})\|_{\Phi} < r
\]

is sufficient to conclude that \( T_{\nu} : B(r, \Delta_{\nu}) \to B(r, \Delta_{\nu}) \) is a contraction (see Lemma 5 and [17]), yielding a unique zero of \( f(\nu, x) \) at \( \nu = \nu_0 + \Delta_{\nu} \). In practice,
we use an iterative procedure (with $\Delta_\nu$ varying) to find the approximate maximal $\Delta_0^\nu$ for which there exists an $r > 0$ such that \(15\) is satisfied; see Section \[2\] and \[11\]. If this step is successful, let $\nu_1 = \nu_0 + \Delta_0^\nu$. We then have a continuum of zeros $C_0 = \{ (\nu, x^0(\nu)) \mid f(\nu, x^0(\nu)) = 0, \ \nu \in [\nu_0, \nu_1] \}$; see Lemma \[4\]. Since we want to repeat the argument with initial parameter value $\nu_1$, we put ourselves in the context of a continuation method. This involves a predictor and corrector step. Recalling \(13\), the predictor at the parameter value $\nu_1 = \nu_0 + \Delta_0^\nu$ is given by $\hat{x}_1 \overset{\text{def}}{=} \hat{x} + \Delta_0^\nu \hat{x}$. The corrector step, based on a Newton-like iterative scheme for the projection $f^{(m)}$, takes $\hat{x}_1$ as its input and produces, within a prescribed tolerance, a zero $\bar{x}_1$ at $\nu_1$.

We can then compute a new tangent vector $\hat{x}_1$, build the new set of predictors $\hat{x}_1 + \Delta_\nu \hat{x}_1$, construct the bounds $Y, Z$ at the parameter value $\nu_1$ and try to verify \(15\) again. If we are successful in finding a new $\Delta_0^\nu$, we let $\nu_2 = \nu_1 + \Delta_0^\nu$ and we get the existence of a continua of zeros $C_1 = \{ (\nu, x^1(\nu)) \mid f(\nu, x^1(\nu)) = 0, \ \nu \in [\nu_1, \nu_2] \}$.

Once we have the two continua of zeros $C_0$ and $C_1$, we ask the natural question: can we prove that $C_0$ and $C_1$ connect at $(\nu_1, x^0(\nu_1)) = (\nu_1, x^1(\nu_1))$ such that $C_0 \cup C_1$ is a smooth one dimensional branch of solutions of $f = 0$? It turns out that there is a simple check that can be added to the continuation step in order to give an answer to this question; see Proposition \[8\].

1.2. Pseudo-arclength continuation. The rigorous continuation introduced in the previous section requires $D_xf(\nu, x)$ to be nonsingular along the branch of zeros we are following. This implies that the continuation method will necessarily fail when trying to continue past a fold. One way to overcome this difficulty is to consider the continuation parameter $\nu$ as a variable and the arclength of the curve as a new parameter \[8\]. Consider the vector of variables $X = (p, \xi)$ and recall \(2\). To solve $F(X) = 0$ past folds, we append one equation to the system, namely the equation $E = 0$ of a plane almost perpendicular to the curve we are following. In practice, we do not know exactly the arclength of the curve. The new continuation parameter, denoted by $s$, will then be the pseudo-arclength of the curve. Note that $E$ depends on $s$. (The details of the construction of $E$ are rather technical and are presented in Section \[3\].) In essence, we apply the rigorous continuation method on $F(s, X) = 0$, where

$$F(s, X) = \begin{pmatrix} E(s, X) \\ f(X) \end{pmatrix}.$$ 

With this construction, note that $D_X F(s, X)$ will be nonsingular at a fold point. Hence, we can expect a Newton-like map to contract neighborhoods of the fold point. In Lemma \[10\] and Proposition \[11\] we formulate the algorithms to establish the existence of a smooth solution curve.

The paper is organized as follows. In Section \[2\] we introduce the parameter continuation method to obtain smooth branches of zeros. In Section \[3\] we show how to modify the continuation method in order to continue past folds: pseudo-arclength continuation. In Section \[4\] we first present an example of the parameter continuation in the context of periodic solutions of delay differential equations. We also discuss an application of the pseudo-arclength method to periodic solutions of ordinary differential equations. This example provides an improvement of a result presented in \[1\].
2. Parameter continuation

In this section, we develop a method to compute smooth solution curves of
\[ F : \mathbb{R}^l \times \Omega \rightarrow \mathbb{R}^l \times \Omega, \]
as we move one of the parameters of \( p \). Without loss of generality, we consider \( \nu = p_1 \) as the continuation parameter. Hence, we fix all parameters \( p_2, \ldots, p_l \).

Defining the infinite dimensional vector of variables \( x = (p_2, \ldots, p_l, \xi) \), we want to do rigorous branch following for the problem \( f(\nu, x) = 0 \). As mentioned before, we transform this problem into a fixed point problem \( T_\nu(x) = x \). With \( x \) as given above, define the norm
\[ \|x\|_\Phi = \max \{|p_2|, \ldots, |p_l|, \|\xi\|_q_1 \} \]
and the corresponding Banach space
\[ \Phi = \{x = (p_2, \ldots, p_l, \xi), \|x\|_\Phi < \infty\}. \]

Consider \( \nu_0 \) fixed and suppose the existence of \( \bar{x} \in \Phi \) such that \( f(\nu_0, \bar{x}) \approx 0 \). Assume we have a bijective linear operator \( A : \mathbb{R}^l \times \Omega \rightarrow \mathbb{R}^{l-1} \times \Omega \) which acts as an approximation for the inverse of \( D_x f(\nu_0, \bar{x}) \). Recalling (13), consider the Newton-like operator \( T_\nu(x) = x - Af(\nu, x) \) with \( \nu \) close to \( \nu_0 \). Suppose also that we have computed a tangent vector \( \dot{x} \in \Phi \) such that \( D_x f(\nu_0, \bar{x}) \dot{x} + D\nu f(\nu_0, \bar{x}) \approx 0 \).

The idea is to find balls in \( \Phi \) on which \( T_\nu \) is a contraction mapping, thus leading to solutions of \( f(\nu, x) = 0 \). Recalling that \( \xi_k \in \mathbb{R}^n \), let us define the ball of radius \( r \) in \( \Phi \), centered at the origin,
\[ B^{q_1}(r) \overset{\text{def}}{=} [-r, r]^{l-1} \times \prod_{k=0}^{\infty} \left[ -\frac{r}{\omega_k}, \frac{r}{\omega_k} \right]^n. \]

We will drop \( q_1 \) from the notation whenever this does not compromise clarity.

Recalling (13), consider the predictors based at \( \nu_0 \): \( x_\nu = \bar{x} + \Delta_\nu \bar{x} \), with \( \Delta_\nu = \nu - \nu_0 \).

For \( \nu \) close to \( \nu_0 \) we define the ball centered at \( x_\nu \) by \( B_{x_\nu}(r) = x_\nu + B(r) \). To simplify the presentation, define \( k_0 = -l_1 + 1 \), so that the indexing of the sets begins at \( k = k_0 \). To show that \( T_\nu \) is a contraction mapping, we need bounds \( Y_k \) and \( Z_k \) for all \( k \geq k_0 \), such that, with \( \Delta_\nu = \nu - \nu_0 \),
\[ \left| T_\nu(x_\nu) - x_\nu \right| \leq Y_k(\Delta_\nu), \]
and
\[ \sup_{b, c \in B(r)} \left| DT_\nu(x_\nu + b)c \right| \leq Z_k(r, \Delta_\nu). \]

Note that \( Y_k, Z_k \in \mathbb{R} \) for \( k_0 \leq k < 0 \) and \( Y_k, Z_k \in \mathbb{R}^n \) for \( k \geq 0 \). As mentioned earlier, we refer to Sections 3.2 and 3.3 in [1] or Section 6 in [5] for explicit computations of the bounds (19) and (20). The following lemma was proved in [1].

**Lemma 5.** Consider \( \nu = \nu_0 + \Delta_\nu \). If there exists an \( r > 0 \) such that \( \|Y + Z\|_\Phi < r \), with \( Y = (Y_k)_{k \geq k_0} \) and \( Z = (Z_k)_{k \geq k_0} \), satisfying (19) and (20), respectively, then \( T_\nu \) is a contraction mapping on \( B_{x_\nu}(r) \) with contraction constant at most \( \|Y + Z\|_\Phi / r < 1 \). Furthermore, there is a unique \( \bar{x}_\nu \in B_{x_\nu}(r) \) such that \( f(\nu, \bar{x}_\nu) = 0 \), and \( \bar{x}_\nu \) lies in the interior of \( B_{x_\nu}(r) \).
For the sake of simplicity of presentation, we assume \( n = 1 \). The generalization of the discussion below for the case \( n \geq 1 \) is straightforward, using componentwise comparison for all vector inequalities concerned. An example with \( n = 2 \) can be found in \([9]\).

The bounds/functions \( Y_k(\Delta_\nu) \) and \( Z_k(r, \Delta_\nu) \) can be constructed so that they are polynomials in \( r \) and \(|\Delta_\nu|\) (note the absolute value) with nonnegative coefficients. Of course, in parameter continuation, at each step one is interested in either \( \Delta_\nu > 0 \) or \( \Delta_\nu < 0 \), but we stick with the general setting since using the sign of \( \Delta_\nu \) will only marginally improve the bounds and step size. Also, for sufficiently large \( k \), say \( k \geq M \), one may choose

\[
Y_k = 0, \quad \text{and} \quad Z_k = \tilde{Z}_M \left( \frac{M}{k} \right)^\nu_1
\]

for some \( \tilde{Z}_M = \tilde{Z}_M(r, \Delta_\nu) > 0 \), where \( M \) is a computational parameter (to be discussed in the example presented in Section \([12]\)). The reason one can choose \( Y_k = 0 \) for \( k \) large enough is because the quantity \([T_\nu(x_\nu) - x_\nu]_k\) eventually vanishes. This is due to the fact that \( x_\nu \) has only finitely many nonzero entries (e.g., see Section 3.2 in \([1]\)). In order to verify the hypotheses of Lemma \([5]\) in a computationally efficient way, we introduce the following notion of radii polynomials.

**Definition 6.** Let \( Y_k(\Delta_\nu) = 0 \) and \( Z_k(r, \Delta_\nu) = \tilde{Z}_M(r, \Delta_\nu)\left( \frac{M}{k} \right)^\nu_1 \) for all \( k \geq M \). We define the radii polynomials \( \{p_{k_0}, \ldots, p_{M-1}, p_M\} \) by

\[
p_k(r, |\Delta_\nu|) = \begin{cases} 
Y_k(\Delta_\nu) + Z_k(r, \Delta_\nu) - \frac{r}{\omega_k}, & \text{if } k = k_0, \ldots, M-1, \\
\tilde{Z}_M(r, \Delta_\nu) - \frac{r}{\omega_M}, & \text{if } k = M,
\end{cases}
\]

where we recall that \( Y_k(\Delta_\nu) = Y_k(|\Delta_\nu|) \) and \( Z_k(r, \Delta_\nu) = Z_k(r, |\Delta_\nu|) \) are polynomials with nonnegative coefficients. In particular, \( p_k \) is increasing in \(|\Delta_\nu|\geq 0\) and convex in \( r \geq 0 \).

Here, we repeat the discussion presented in \([1]\), as it sheds light on the reason the radii polynomials \( p_k \) are useful. Some terms of the polynomials \( Y_k \) and \( Z_k \) are close to zero. More precisely,

\[
Y_k \sim \delta_1 + \delta_2 |\Delta_\nu| + O(\Delta_\nu^2),
\]

\[
Z_k \sim \delta_3 r + O(\Delta_\nu r, r^2),
\]

where \( \delta_1, \delta_2 \) and \( \delta_3 \) are very small: \( \delta_1 \approx 0 \) because of the choice of \( \tilde{x} \), \( \delta_2 \approx 0 \) because of the choice of \( \hat{x} \), and \( \delta_3 \approx 0 \) because of the choice of the linear operator \( A \) and the Newton-like map \( T_\nu \). Therefore, the radii polynomials are roughly of the form

\[
p_k(r, |\Delta_\nu|) \sim (\delta_1 + |\Delta_\nu|\delta_2) - \left( \frac{1}{\omega_k} - \delta_3 \right) r + O(r^2, \Delta_\nu r, \Delta_\nu^2).
\]

Hence, for a reasonably large range of \( \Delta_\nu \), one may anticipate finding a small \( r > 0 \) (but not too small) at which all radii polynomials are negative. The following is a slight modification of a result presented in \([1]\).

**Lemma 7.** Recall \([2]\) and suppose that \( F \in C^\ell \left( \mathbb{R}^{d_1} \times B_1, \mathbb{R}^{d_2} \times B_2 \right) \), \( \ell \geq 1 \). If there exists an \( r > 0 \) and a small \( \Delta_\nu \) such that \( p_k(r, |\Delta_\nu|) < 0 \) for all \( k = k_0, \ldots, M \), then there exists a \( C^\ell \) function \( \tilde{x} : [0_\nu - \Delta_\nu, 0_\nu + \Delta_\nu] \to \Phi : \nu \mapsto \tilde{x}(\nu) \) such that \( f(\nu, \tilde{x}(\nu)) = 0 \) for all \( \nu \in [0_\nu - \Delta_\nu, 0_\nu + \Delta_\nu] \). Furthermore, these are the only solutions of \( f(\nu, x) = 0 \) in the tube \( \{0_\nu \leq \Delta_\nu, x - x_\nu \in B(r)\} \).
Proof. Since \( p_k \) is increasing in \( |\Delta_\nu| \geq 0 \), existence and uniqueness of a solution \( \overline{x}(\nu) \) for \( \nu \in [\nu_0 - \Delta_\nu, \nu_0 + \Delta_\nu] \) follows from the definition of the radii polynomials and Lemma 5. In particular, for every fixed \( \nu \in [\nu_0 - \Delta_\nu, \nu_0 + \Delta_\nu] \), \( T_\nu : B_{\nu_0} \to B_{\nu} \) is a contraction. Consider the change of variable \( y = x - x_\nu \). Then, the operator

\[
\overline{T} : [\nu_0 - \Delta_\nu, \nu_0 + \Delta_\nu] \times B(\nu) \to B(\nu) : (\nu, y) \mapsto \overline{T}(\nu, y) \overset{\text{def}}{=} T_\nu(y + x_\nu)
\]

is a uniform contraction on \( B(\nu) \). Since \( F \in C^\ell \left( \mathbb{R}^1 \times B_1, \mathbb{R}^2 \times B_2 \right) \), we have that \( \overline{T} \in C^\ell \left( [\nu_0 - \Delta_\nu, \nu_0 + \Delta_\nu] \times B(\nu), B(\nu) \right) \). By the uniform contraction principle (see e.g., [3]), we conclude that \( \overline{x}(\nu) \) is a \( C^\ell \) function of \( \nu \).

After one successful step, based at \((\nu, x) = (\nu_0, \tilde{x}_0)\) with predictor \( \tilde{x}_0 \) and step size \( \Delta_{\nu_1} \), we find the corrector \( \tilde{x}_1 \) at \( \nu = \nu_1 = \nu_0 + \Delta_{\nu_1} \) using a Newton iteration, and we rebuild the radii polynomials, now based at \((\nu, x) = (\nu_1, \tilde{x}_1)\). Suppose now that we have performed two successful continuation steps; i.e., in both steps we have found radii \( r_0 \) and \( r_1 \), respectively, where the radii polynomials are negative.

We thus have two continuous solution graphs over intervals \([\nu_0, \nu_1]\) and \([\nu_1, \nu_2]\): Lemma 7 implies the existence of two functions \( x^0(\nu) \) and \( x^1(\nu) \) of class \( C^\ell \) such that \( C_0^\ell = \left\{(\nu, x^0(\nu)) : \nu \in [\nu_0, \nu_1] \right\} \) and \( C_1^\ell = \left\{(\nu, x^1(\nu)) : \nu \in [\nu_1, \nu_2] \right\} \) are smooth branches of solutions of \( f(\nu, x) = 0 \). The question is to determine whether or not \( C_0 \) and \( C_1 \) connect at the parameter value \( \nu_1 \) to form a smooth continuum of zeros \( C_0 \cup C_1 \). In other words, can we prove that \( x^0(\nu_1) = x^1(\nu_1) \) and that the connection is smooth? It turns out that validated continuation is well suited to answer this question. At the parameter value \( \nu_1 \), we have two sets enclosing a unique zero, namely

\[
B_0^\ell = \tilde{x}_0 + (\nu_1 - \nu_0) \tilde{x}_0 + B(r_0)
\]

and

\[
B_1^\ell = \tilde{x}_1 + B(r_1).
\]

We want to prove that the solutions in \( B_0 \) and \( B_1 \) are the same. We return now to the radii polynomials \( p_k(\nu, |\Delta_\nu|) \), \( k = k_0, \ldots, M \), constructed at basepoint \((\nu, x) = (\nu_1, \tilde{x}_1)\), and evaluate them at \( \Delta_{\nu_1} = 0 \):

\[
\tilde{p}_k(r) \overset{\text{def}}{=} p_k(r, 0).
\]

Since \( \tilde{p}_k(r_1) < 0 \), we find a nonempty interval \( I \overset{\text{def}}{=} [r_1^-, r_1^+] \) containing \( r_1 \) such that \( \tilde{p}_k(r) \) are all strictly negative on \( I \). We now have two additional sets enclosing a unique zero at parameter value \( \nu_1 \), namely

\[
B_1^\ell = \tilde{x}_1 + B(r_1^+).
\]

**Proposition 8.** If \( B_0 \subset B_0^+ \) or \( B_1^- \subset B_0 \), then \( C_0 \cup C_1 \) consists of a continuous branch of solutions of \( f(\nu, x) = 0 \), and \( C_0 \cap C_1 = \{(\nu_1, x^0(\nu_1))\} = \{(\nu_1, x^1(\nu_1))\} \subseteq B_0 \cap B_1 \). Moreover, if \( T(\nu, x) = T_\nu(x) \) is of class \( C^\ell \), then \( C_0 \cup C_1 \) is a \( C^\ell \) smooth curve.

**Proof.** For a geometric representation of the proof, we refer to Figure 1. The sets \( B_1^- \), \( B_1^+ \) and \( B_1 \) all contain a unique zero of \( f(\nu_1, \cdot) \). Since the balls are nested, these zeros are one and the same, namely \( x^1(\nu_1) \). Furthermore, \( B_0 \) also contains exactly one zero of \( f(\nu_1, \cdot) \), namely \( x^0(\nu_1) \). This assertion implies that either \( B_0 \) and \( B_1^+ \), or \( B_0 \) and \( B_1^- \) are nested, hence \( x^0(\nu_1) = x^1(\nu_1) \). This means that \( C_0 \cup C_1 \) consists of a one dimensional continuous branch of zeros of \( f \). It remains for us to prove smoothness at \( \nu = \nu_1 \). By Lemma 7, \( x^1(\nu) \) is a smooth \( C^\ell \) function on the
Figure 1. $B_0 \cap B_1$ contains a unique zero of (12) and $C_0 \cup C_1$ consists of a continuum of zeros. This picture illustrates the proof of Proposition 8.

interval $[\nu_1 - \Delta_\nu, \nu_1 + \Delta_\nu]$. Moreover, we assert that $x^0(\nu)$ and $x^1(\nu)$ coincide on $[\nu_1 - \epsilon, \nu_1]$ for $\epsilon > 0$ sufficiently small. Namely, $x^1(\nu)$ lies in the interior of the tube $\{(\nu, x) \mid |\nu - \nu_1| \leq \Delta_\nu, x - (\bar{x}_1 + (\nu - \nu_1)\dot{x}_1) \in B(r_1)\}$, and $(\nu, x^1(\nu))$ are the only zeros of $f$ inside this tube. On the other hand, the solution curve $x^0(\nu)$ must enter the tube for $\nu$ close to $\nu_1$, since $x^0(\nu_1)$ is in the interior. From uniqueness of solutions inside the tube (Lemma 7) it follows that indeed $x^0(\nu)$ and $x^1(\nu)$ coincide on $[\nu_1 - \epsilon, \nu_1]$ for $\epsilon > 0$ sufficiently small. Hence, we conclude that the union $C_0 \cup C_1$ is $C^\ell$ smooth. □

In practice, the hypotheses of Proposition 8 are verified as follows. The center points $\bar{x}_0 + (\nu_1 - \nu_0)\dot{x}_0$ of $B_0$ and $\bar{x}_1$ of $B_1$, $B^\pm_1$ are computed using the finite dimensional approximations $f^{(m_0)}$ and $f^{(m_1)}$ of $f$, respectively. This means that $\bar{x}_0 + (\nu_1 - \nu_0)\dot{x}_0 \in \mathbb{R}^{m_0}$ and $\bar{x}_1 \in \mathbb{R}^{m_1}$. Let $\bar{m} = \max\{m_0, m_1\}$. Recalling (13), let $q_0$ and $q_1$ be the decay rates of the tails of $B_0$ and $B_1$, respectively. Note that $B_1$, $B^-_1$ and $B^+_1$ have the same decay rate. If $q_0 < q_1$, the tail of $B^+_1$ decays faster than the tail of $B_0$, which clearly means that $B_0 \not\subset B^+_1$. Hence, we have to check whether or not $B^-_1 \subset B_0$ by verifying that the product of the first $\bar{m}$ intervals of $B^-_1$ is a subset of the product of the $\bar{m}$ first intervals of $B_0$ (this consists of checking $2\bar{m}$ inequalities on a computer) and checking that $r^-_1 < r_0$. This will ensure that $B^-_1 \subset B_0$. Similarly, if $q_0 > q_1$, we can only investigate that $B_0 \subset B^+_1$. We proceed as before; that is, we verify the inclusion of the $\bar{m}$ dimensional finite part of the sets and then check that $r_0 < r^+_1$. If $q_0 = q_1$, we have the choice. For instance, we can start by verifying that $B_0 \subset B^+_1$. If it is true, we stop. If not, we determine whether or not $B^-_1 \subset B_0$. If we can show that $B^-_1 \subset B_0$, then we have the desired continuum. If not, we cannot conclude anything about the continuity of the branch.
3. PSEUDO-ARC LENGTH CONTINUATION

In this section, we adapt the continuation method presented in Section 2 to pseudo-arclength continuation. In general, there may be no preferred parameter in which one wants to continue, or if there is, one would like to continue past folds. This is where pseudo-arclength continuation comes into the picture [8]. The first step is to reformulate the problem so that $D_x f(\nu, x)$ being singular is no longer an obstruction for the method.

3.1. Avoiding the singularity of the derivative. Considering $X = (p, \xi)$, where all parameters $p$ are now variables, we want to solve $F(X) = 0$, where $F$ is given by (2), restricted to a plane almost perpendicular to the branch of zeros we are following; see [8]. Suppose that we have a predictor $\hat{X}$ and some guess about the direction $\dot{X}$ of the curve, then one can define the plane $(X - \hat{X}) \cdot \dot{X} = 0$. This plane is transverse to the curve and contains the predictor. Appending the equation of the plane to $F$, we consider

$$F(X) \overset{\text{def}}{=} \begin{pmatrix} (X - \hat{X}) \cdot \dot{X} \\ F(X) \end{pmatrix} = 0.$$

In this setting, a generic fold point $\bar{X}$ is hyperbolic; that is, $D_X F(\bar{X})$ is nonsingular. Hence, we can expect a contraction mapping argument to be successful. For a geometric representation, we refer to Figure 2.

3.2. PIECEWISE SMOOTH SOLUTION CURVES. We now incorporate the discussion of Section 3.1 into the context of a predictor-corrector algorithm. From a previous step, we have a direction vector $\dot{X}_0$, and suppose we have computed an approximate solution $\dot{X}_1$ of $F(X) = 0$ in a plane perpendicular to $\dot{X}_0$. We want to construct the radii polynomials based at $\dot{X}_1$. We numerically compute $\dot{X}_1$ such that $D F(\dot{X}_1) \dot{X}_1 \approx 0$. Then, fixing $\Delta_s > 0$ (to be determined later), we define the predictors

$$X_s = \ddot{X}_1 + s \Delta_s \dot{X}_1,$$

$$X'_s = \dot{X}_0 + s(\ddot{X}_1 - \dot{X}_0), \quad s \in [0, 1].$$

FIGURE 2. Solving $F(X) = 0$ on the plane $(X - \hat{X}) \cdot \dot{X} = 0$. 

License or copyright restrictions may apply to redistribution; see http://www.ams.org/journal-terms-of-use
Using these, we introduce a family of planes

\[(22) \quad \Pi_s = \{(s, X) \mid E(s, X) \overset{\text{def}}{=} (X - X_s) \cdot X'_s = 0\},\]

where \(X \cdot Y\) denotes an inner product (in practice we use the usual dot product in Euclidean space, since \(X_s\) and \(X'_s\) only have finitely many nonzero components). The family \(\{\Pi_s \mid s \in [0, 1]\}\) is an interpolation between the plane \(\Pi_0\) from the previous step and the plane \(\Pi_1\) perpendicular to the predictors \(X_s\); see Figure 3. Note that we can choose \(\dot{X}_1\) to be approximately of unit length and such that \(\dot{X}_0 \cdot \dot{X}_1\) is positive, so that \(\dot{X}_0\) and \(\dot{X}_1\) point roughly in the same direction (and we do not back trace on the solution curve). When we set \(P = (s, p)\) and \(H = (E, h)\), then we are in the setting of parameter continuation introduced in Section 2, for zeros of \(\mathbf{F}(P, \xi) = (H, g)\), except that the first equation \(E = 0\) changes at each step in the iterative continuation process (which has some consequences for matching the piecewise continuous solution curves, as discussed in Section 3.3). The set of equations is more conveniently written as

\[(23) \quad \mathbf{F}(s, X) = \begin{pmatrix} E(s, X) \\ \mathcal{F}(X) \end{pmatrix}.\]

We point out one difference in notation compared to parameter continuation, namely, a single continuation step is always described by \(s \in [0, 1]\), while \(\Delta_s\) controls the length of the step (pseudo-arclength). As in parameter continuation, we do not need to fix the step size a priori, allowing us to choose a near optimal \(\Delta_s\) at each continuation step.

**Remark 9.** Alternative choices of (21) can be made. For example, here we describe how to obtain a \(C^1\) representation of the curve. One can compute two nearby approximate solutions \(\bar{X}_0\) and \(\bar{X}_1\) on the solution curve (and thereby thus also fixing the step size), as well as corresponding direction vectors \(\dot{X}_0\) and \(\dot{X}_1\). Then, for \(s \in [0, 1]\), we set

\[X_s = s^3[\bar{X}_1 - \bar{X}_0 - 2(\bar{X}_1 - \bar{X}_0 - \bar{X}_0)] + s^2[3(\bar{X}_1 - \bar{X}_0 - \bar{X}_0) - (\bar{X}_1 - \bar{X}_0)] + s\bar{X}_0 + \bar{X}_0\]

and \(X'_s = \frac{d}{ds}X_s\). Hence, \(X'_0 = \bar{X}_0\) and \(X'_1 = \dot{X}_1\). We can then look for zeros of (23), with \(E(s, X) \overset{\text{def}}{=} (X - X_s) \cdot X'_s\). The advantage of such a choice is the global \(C^1\)
representation of the predictors $X_s$, whereas the downside is a significantly larger number of terms in the estimates, as well as the need to fix a priori the distance between successive points.

We look to uniquely enclose zeros of \((23)\) in sets of the form $B_X(r) = X_s + B(r)$, where
\[
B(r) = [-r, r]^l_i \times \prod_{k=0}^{l_i} \left[ -\frac{r}{\omega_k}, \frac{r}{\omega_k} \right].
\]
As before, we set up an equivalent fixed point problem. Suppose that, numerically, we found an approximation $\tilde{X}^1(s)$ of class $C^r$, we can conclude that the function $\tilde{X}^1(s)$ is of class $C^r$; see Lemma 7. We now address the question of the smoothness of the curve
\[
\mathcal{C} = \{ \tilde{X}^1(s) \mid F(s, \tilde{X}^1(s)) = 0, \; s \in [0, 1] \}.
\]

**Lemma 10.** Recall \((21)\) and suppose that $\bar{X}_0, \bar{X}_1 \in \mathbb{R}^{m + l_i}$. Define
\[
\kappa_1 \overset{\text{def}}{=} \frac{1}{\Delta_s} \sum_{k=k_0}^{l_r-1} |(\bar{X}_1 - \bar{X}_0)_k| + \sum_{k=0}^{m-1} \frac{1}{\omega_k} |(\bar{X}_1 - \bar{X}_0)_k|,
\]
\[
\kappa_2 \overset{\text{def}}{=} \min\{ \bar{X}_1 \cdot \bar{X}_0, \bar{X}_1 \cdot \bar{X}_1 \},
\]
where $\omega_k$ is the decay rate of the set $B(r)$. Let $r_1 > 0$ and $\Delta_s > 0$ such that $p_k(r_1, \Delta_s) < 0$, for all $k = k_0, \ldots, M$. If
\[
\kappa_1 r_1 < \Delta_s \kappa_2,
\]
then $\mathcal{C}$ is a smooth curve.

**Proof.** We will show that the parametrization $\tilde{X}^1(s)$ is such that $\frac{d\tilde{X}^1}{ds}(s)$ never vanishes, implying that $\mathcal{C}$ is a smooth curve. Note that $\kappa_1, \kappa_2 \geq 0$, since $\bar{X}_1$ is chosen so that $\bar{X}_1 \cdot \bar{X}_0 \geq 0$. We prove that $\frac{d\tilde{X}^1}{ds}(s) \neq 0$, for all $s \in [0, 1]$. The definition of $\mathcal{C}$ implies that $E(s, \tilde{X}^1(s)) = 0$, for all $s \in [0, 1]$. Hence, for all $s \in [0, 1]$, we get that
\[
\frac{\partial E}{\partial s}(s, \tilde{X}^1(s)) + \frac{\partial E}{\partial \bar{X}}(s, \tilde{X}^1(s)) \frac{d\tilde{X}^1}{ds}(s) = 0.
\]
Recalling \((21)\) and \((22)\), we show that the first term does not vanish:
\[
\frac{\partial E}{\partial s}(s, \tilde{X}^1(s)) = -\Delta_s \bar{X}_1 \cdot X'_s + (X - X_s) \cdot (\bar{X}_1 - \bar{X}_0) \neq 0.
\]
Let us estimate the two terms separately. Since \( s \in [0, 1] \) and \( \Delta_s > 0 \),
\[
\Delta_s \dot{X}_1 \cdot X'_s = \Delta_s [\dot{X}_1 \cdot X_0 + s(\dot{X}_1 \cdot \dot{X}_1 - \dot{X}_1 \cdot X_0)] \\
\geq \Delta_s \min \{\dot{X}_1 \cdot X_0, \dot{X}_1 \cdot \dot{X}_1\} \\
= \Delta_s \kappa_2.
\]
Since \( \tilde{X}_1(s) - X_s \in B(r_1) \),
\[
\left| (\tilde{X}_1(s) - X_s) \cdot (\dot{X}_1 - \dot{X}_0) \right| \leq -\sum_{k=k_0}^{-1} |(\dot{X}_1 - \dot{X}_0)_k| r_1 + \sum_{k=0}^{m-1} \frac{1}{\omega_k} |(\dot{X}_1 - \dot{X}_0)_k| r_1 \\
= \kappa_1 r_1.
\]
It follows that \( \frac{\partial E}{\partial s}(s, \tilde{X}_1(s)) \leq -\Delta_s \kappa_2 + \kappa_1 r_1 < 0 \), for all \( s \in [0, 1] \). We conclude from (26) that \( \frac{d \tilde{X}_1}{ds}(s) \neq 0 \), for all \( s \in [0, 1] \). By the implicit function theorem, \( \mathcal{C} \) is a smooth curve.

In practice, we verify condition (26) at the end of the continuation step, that is, when we have found an \( r_1 > 0 \) and the approximately maximal \( \Delta_s \) such that \( p_k(r_1, \Delta_s) < 0 \) for all \( k = k_0, \ldots, M \). We compute \( \kappa_1 \) and \( \kappa_2 \) and then check that \( \kappa_1 r_1 - \Delta_s \kappa_2 < 0 \).

3.3. Matching the piecewise smooth solution curves. In Section 3.2, we introduced the theory for computing smooth pieces of solution curves. In this section, we show how to glue these pieces to form a global smooth solution curve. Suppose that we have performed two successful pseudo-arclength continuation steps and obtained two smooth pieces of solution curves \( C^0 \equiv \{\tilde{X}_0(s), s \in [0, 1]\} \) and \( C^1 \equiv \{\tilde{X}_1(s), s \in [0, 1]\} \) of \( F(X) = 0 \), with \( C^0 \) originating in \( \Pi_0^0 \) and ending in \( \Pi_1^0 \)
Consider the sets
\begin{equation}
B_0 \overset{\text{def}}{=} B(r_0) + \hat{X}_1 \quad \text{and} \quad B_1 \overset{\text{def}}{=} B(r_1) + \hat{X}_1,
\end{equation}
each enclosing a unique zero of $\mathcal{F}$ on $\Pi^0_1$ and $\Pi^0_0$, respectively. Note that there might be a small distance between the planes $\Pi^0_1 : (X - \hat{X}_1) \cdot \hat{X}_0 = 0$ and $\Pi^0_0 : (X - \hat{X}_1) \cdot \hat{X}_0 = 0$. Indeed, $\hat{X}_1$ was numerically computed such that
\begin{equation}
\delta \overset{\text{def}}{=} \left| (\hat{X}_1 - \hat{X}_1) \cdot \hat{X}_0 \right| \approx 0,
\end{equation}
but exact equality cannot be guaranteed. We remark that if $\hat{X}_0$ is computed so that $\|\hat{X}_0\| \approx 1$, then $\delta$ is a very good approximation of the distance between the parallel planes $\Pi^0_1$ and $\Pi^0_0$ (see Figure 3).

We need to fill the gap between the planes. Consider
\[
\bar{\Pi}_x : \bar{E}(\tau, X) \overset{\text{def}}{=} (X - \hat{X}_1) \cdot \hat{X}_0 + \tau = 0, \quad \tau \in [-\delta, \delta],
\]
the interpolation with parallel planes between $\Pi^0_0$ for $\tau = 0$ and $\Pi^0_0$ for $\tau = \pm \delta$ (depending on the sign of $(\hat{X}_1 - \hat{X}_1) \cdot \hat{X}_0$). As in Section 3.2, we would like to find uniform $r_1^+ > r_1^- > 0$ such that $B_{\hat{X}_1}(r_1^-)$ and $B_{\hat{X}_1}(r_1^+)$ both contain, for all $\tau \in [-\delta, \delta]$, a unique zero of
\begin{equation}
\bar{F}(\tau, X) \overset{\text{def}}{=} \left( \begin{array}{c}
\bar{E}(\tau, X) \\
\mathcal{F}(X)
\end{array} \right).
\end{equation}

Let $A$ be the operator used in the construction of the radii polynomials based at $\hat{X}_1$. In other words, $A$ was used to define the uniform contraction $T$ that yielded the existence of $C^1$. Define $\bar{T}_x(X) = X - A\bar{F}(\tau, X)$ and consider the uniform predictor $\bar{X}_1$ for all $\tau \in [-\delta, \delta]$. For every $\tau \in [-\delta, \delta]$, we want to enclose a unique fixed point of $\bar{T}_x$ in $B_{\hat{X}_1}(\tau)$, for some $\tau > 0$. Consider the radii polynomials $\tilde{p}_k(\tau, |\tau|)$, $k = k_0, \ldots, M$, associated to this problem. Recalling (19) and (20), we note that the bound $Z$ does not depend on $\tau$, while the bound $Y$ depends on $|\tau|$ linearly; see equations (31) and (32) below. Note that $\tilde{p}_k(\tau, |\tau|) \leq \tilde{p}_k(\tau, \delta)$, for all $k$ and for all $\tau \in [-\delta, \delta]$. Suppose that there exist $r_1^+ > r_1^- > 0$ such that $\tilde{p}_k(r_1^+, \delta) < 0$ and $\tilde{p}_k(r_1^-, \delta) < 0$, for all $k = k_0, \ldots, M$. Hence, for any given $\tau \in [-\delta, \delta]$, the sets
\begin{equation}
B_1^+ \overset{\text{def}}{=} B_{\hat{X}_1}(r_1^+) = \hat{X}_1 + B(r_1^+)
\end{equation}
contain a unique zero of (29). By Lemma 7 we get the existence of
\[
C^{0,1} \overset{\text{def}}{=} \left\{ \bar{X}^{0.1}(\tau) \mid \bar{F}(\tau, \bar{X}^{0.1}(\tau)) = 0, \quad \tau \in [-\delta, \delta] \right\},
\]
where $\bar{X}^{0.1}(\tau)$ is a smooth function. In the context of pseudo-arclength continuation, the following result is the analogue of Proposition 8.

**Proposition 11.** Suppose that $C^0$ and $C^1$ are smooth curves. If $B_0 \subset B_1^+$ or $B_1^- \subset B_0$, then $C^0 \cup C^{0,1} \cup C^1$ consists of a smooth solution curve of $\mathcal{F}(X) = 0$.

**Proof.** We show that $C^0$ and $C^1$ connect smoothly via $C^{0,1}$. First note that $B_1^\pm$ and $B_1$ all uniquely enclose a zero of $\mathcal{F}$ in the plane $\Pi^0_1$. Since these balls are nested, these zeros are the same, namely $\bar{X}^{0.1}(0) = \bar{X}^1(0)$. Note also that $B_1^\pm$ and $B_0$ all uniquely enclose a zero of $\mathcal{F}$ in the plane $\Pi^0_0$. By hypothesis, $B_0$ and $B_1^+$ are nested or $B_1^-$ and $B_0$ are nested, implying that $\bar{X}^{0.1}(\pm \delta) = \bar{X}^0(1)$. This settles continuity of $C^0 \cup C^{0,1} \cup C^1$. Smoothness of $C^{0,1}$ follows immediately (as in the proof of Lemma 10), since $\frac{\partial \bar{E}}{\partial \tau} = 1$. Furthermore, combining the continuity of the
polynomials \( \tilde{p}_k \) and the fact that \( \tilde{p}_k(r_1, \delta) < 0 \), we infer the existence of an \( \varepsilon > 0 \) such that \( \tilde{p}_k(r_1, \delta + \varepsilon) < 0 \). The smooth solution curve \( \{(r, \bar{X}^{0,1}(r)), |r| \leq \delta + \varepsilon\} \), which slightly elongates \( C^{0,1} \), overlaps (at the ends) with \( C^0 \) and \( C^1 \), by arguments analogous to those used in the proof of Proposition 8. Hence, we conclude that \( C^0 \) and \( C^1 \) connect smoothly via \( C^{0,1} \). \( \square \)

In practice, the construction of the radii polynomials \( \tilde{p}_k(r, |\tau|) \) is very little extra work. Indeed, consider the radii polynomials \( p_k(r, \Delta_s) \), \( k = k_0, \ldots, M \), based at \( \bar{X}_1 \), which were used to draw conclusions about the existence of \( C^1 \). Let \( Y_k(\Delta_s) \) and \( Z_k(r, \Delta_s) \) be the bounds used in the construction of \( p_k(r, \Delta_s) \). Recalling the definition of (29), we first realize that

\[
\sup_{b, c \in B(r)} |D\bar{T}_\tau(\bar{X}_1 + b)c|_k \leq Z_k(r, 0),
\]

for all \( k = k_0, \ldots, M \). This is due to the fact that \( D\bar{F}(\tau, X) = DF(0, X) \). Furthermore, using the triangle inequality, we get that

\[
|\bar{T}_\tau(\bar{X}_1) - \bar{X}_1|_k = \left| -A\bar{F}(\tau, \bar{X}_1) \right|_k
\]

\[
= \left| \left[ -A \left( \begin{array}{c} \tau \\ 0 \end{array} \right) \right] \right|_k + \left| \left[ -A \left( \begin{array}{c} 0 \\ F(\bar{X}_1) \end{array} \right) \right] \right|_k
\]

\[
\leq |\tau||A_{1,k}| + Y_k(0),
\]

by the definition of \( Y_k \). Combining (31) and (32), we conclude that

\[
\tilde{p}_k(r, |\tau|) = p_k(r, 0) + |\tau||A_{1,k}|.
\]

Thus, the difference between the construction of \( \tilde{p}_k \) and \( p_k \) is given in (33).

4. Applications

In this section, we introduce two applications of the method by which we compute global smooth solution curves of differential equations. The first application, in the context of delay equations, uses the parameter continuation method of Section 2; the second one, in the context of ordinary differential equations, uses the pseudo-arclength method of Section 6.

4.1. Periodic solutions of delay equations. In [9], the parameter continuation method introduced in Section 2 is applied to the so-called Wright’s equation

\[
y'(t) = -\alpha y(t - 1)[1 + y(t)], \quad \alpha > \frac{\pi}{2}.
\]

The continuation argument is used to compute a continuous branch \( \mathcal{F}_0 \) of slowly oscillating periodic solutions (SOPS) of (34) and to show (rigorously) that \( \mathcal{F}_0 \) does not have any fold points on the parameter interval \( \left[ \frac{\pi}{2} + \varepsilon, 2.24 \right] \), where \( \varepsilon = 7.3165 \times 10^{-4} \). This result is an attempt to partially answer the conjecture that equation (34) has a unique SOPS for every \( \alpha > \frac{\pi}{2} \). A representation of the rigorously computed branch of SOPS is shown Figure 5. The details of the construction of the radii polynomials and the main results of this problem can be found in [9].
4.2. Forcing theorem and periodic solutions of ordinary differential equations. As was mentioned in Example 1, we are interested in computing periodic solutions of the Swift-Hohenberg equation

\[-u'''' - \nu u'' + u - u^3 = 0\]

with a special symmetry at the zero energy level \(E = 0\). In [1], a rigorous continuation argument in the parameter \(\nu\) was used to prove the following result.

**Proposition 12.** For every \(\nu \in [0, 2]\), the dynamics of the Swift-Hohenberg ordinary differential equation (6) on the energy level \(E = 0\) is chaotic in the sense that there exists a two dimensional Poincaré return map that has a compact invariant set on which the topological entropy is positive.

The reason the continuation is stopped at \(\nu = 2\) is the apparent existence of a saddle-node bifurcation (a fold) at \(\nu \approx 2.03165\).

In what follows, we extend Proposition 12 by using the rigorous pseudo-arclength continuation introduced in Section 3 to continue through the fold. Define \(X = (\nu, L, \xi_0, \xi_1, \xi_2, \ldots)\) and

\[h(X) \overset{\text{def}}{=} -2L^2 \sum_{l=1}^{\infty} l^2 \xi_l - \frac{1}{\sqrt{2}} \left[ \xi_0 + 2 \sum_{l=1}^{\infty} \xi_l \right]^2 + \frac{1}{\sqrt{2}},\]

and for all \(k \geq 0\),

\[g_k(X) \overset{\text{def}}{=} [1 + \nu L^2 k^2 - L^4 k^4] \xi_k - \sum_{k_1 + k_2 + k_3 = k} \xi_k \xi_k \xi_k,\]

where \(\xi_{-k} \overset{\text{def}}{=} \xi_k\). Define \(F = (h, g_0, g_1, g_2, \ldots)^T\). Let us describe the algorithm, where we focus on the differences with the parameter continuation in [1] (see in particular Procedure 16 and the bounds in Sections 3.2 and 3.3 in [1]).

From a previous step, assume that we computed a smooth solution curve \(C_0\) and a direction vector \(\dot{X}_0\). Here are the steps to fulfill in order to prove existence of (and compute) another piece of smooth solution curve \(C_1\) and to glue it smoothly to \(C_0\):

1. Using a finite dimensional approximation \(F^{(m)} : \mathbb{R}^{m+2} \rightarrow \mathbb{R}^{m+2}\), we compute an approximate zero \(\hat{X}_1\) of \(F\) on a plane perpendicular to \(\hat{X}_0\). We also...
compute a new direction vector $\dot{X}_1$ such that $D\mathbf{F}(\dot{X}_1)\dot{X}_1 \approx 0$. Knowing $\dot{X}_0$, $\dot{X}_1$ and $\dot{X}_1$, we build the predictors defined in (21), the family of planes \{ $\Pi_s \mid s \in [0,1]$ \} defined in (22) and the augmented map $\mathbf{F}(s,X)$ defined in (23).

2. We compute the derivative $D_X \mathbf{F}(M)(\dot{X}_1)$, where we choose the computational parameter $M = 3m - 2$ (see [1]), and a numerical approximation $J_M$ of its inverse. We define $\mu_k(L,\nu) = 1 + \nu L^2 k^2 - L^4 k^4$, the part of $g_k$ which is linear in the Fourier modes $\xi_k$. We define the linear operator $A$ on sequence spaces by

\[
A \overset{\text{def}}{=} \begin{bmatrix} J_M & 0 & 0 & 0 & \cdots \\
0 & \mu_M(\bar{L},\bar{\nu})^{-1} & 0 & 0 & \cdots \\
0 & 0 & \mu_{M+1}(\bar{L},\bar{\nu})^{-1} & 0 & \cdots \\
0 & 0 & 0 & \mu_{M+2}(\bar{L},\bar{\nu})^{-1} & \cdots \\
\vdots & \vdots & \vdots & \ddots & \ddots
\end{bmatrix}.
\]

In order to make sure that $A$ is bijective, using interval arithmetic we verify that $\|J_M D_X \mathbf{F}(M)(\dot{X}_1) - I\|_{\infty} < 1$ (with $I$ the $3m \times 3m$ identity matrix).

3. We set $T_s(X) = X - AF(X,s)$. We construct the bound $Y$ defined componentwise by (19). Let us mention that since $\nu$ is considered a variable (as opposed to a parameter), $\bar{\nu}$ and $\bar{\nu}$ (the first components of $\bar{X}_1$ and $\bar{X}_1$, respectively) will appear in $Y$. For a complete description of how to compute the bound $Y(\Delta_k)$, we refer to [1]. Notice also that $F_{-2}(X_s) = 0$. Next we construct $Z$ defined by (20), again including $\nu$ as a variable. Otherwise, the only difference with the construction in [1] is the fact that we need to compute an upper bound $Z_{-2}(r,\Delta_k)$. Without repeating the framework of [1] (in particular we refer the reader to [1] for the precise definition of $A^1$, the approximate inverse of $A$), we note that for $k = -2$,

\[
([DF](s,X_0 + b) - A^1)c_{-2} = DE(s,X_0 + b)c - \dot{X}_0^T \cdot c = (X^*_r - \dot{X}_0)^T \cdot c = s(\dot{X}_1 - \dot{X}_0)^T \cdot c = [\dot{X}_1 - \dot{X}_0]^T \cdot v_F] rs.
\]

Defining $C_{-2}^{1,0} = |(\dot{X}_1 - \dot{X}_0)^T \cdot v_F|$, we get that for every $b,c \in B(r)$ and $s \in [0,1]$,

\[
|([DF](X_0 + b,s) - A^1)c_{-2}| \leq C_{-2}^{1,0} r.
\]

Incorporating $C_{-2}^{1,0}$ in Table 3 in [1], we have all the ingredients to build the $Z(r,\Delta_k)$. Note that Table 3 in [1] contains the coefficients of the polynomials $Z_k(r,\Delta_k)$ defined by (20). We construct the radii polynomials $p_k(r,\Delta_k)$, $k = -2,\ldots,M$, defined in Definition 6. We compute $r_1 > 0$ and an approximately maximal $\Delta_k > 0$ (if they exist and are computable) such that $p_k(r,\Delta_k) < 0$. Recalling Lemma 10, we construct $\kappa_1$ and $\kappa_2$ and verify inequality (25). If the inequality is satisfied, we combine Lemma 7 and Lemma 10 to conclude the existence of the new piece of smooth solution curve $C^1$. 

\[\text{License or copyright restrictions may apply to redistribution; see}\ http://www.ams.org/journal-terms-of-use\]
4. We compute $\delta$ defined in (28), recall (33) and construct the radii polynomials $\tilde{p}_k(r, |\tau|)$. If we can show the existence of $r_1^+ > r_1^- > 0$ such that $\tilde{p}(r_1^+, \delta), \tilde{p}(r_1^-, \delta) < 0$, we construct the sets $B_0, B_1$ and $B_1^\pm$ defined in (27) and (30). If we can show that the hypothesis of Proposition 11 is satisfied, that is, if we can show that $B_0 \subset B_1^+$ or $B_1^- \subset B_0$, then we may conclude that $C_0$ and $C_1$ connect smoothly via $C^0,1$.

We have successfully iterated the above steps for the Swift-Hohenberg problem. This proves the existence of a global smooth branch of periodic solutions of (6) at the energy level $\mathcal{E} = 0$; see Figure 6 (the additional geometric property needed in [1] is also satisfied). We thus obtain the following corollary, generalizing Proposition 12.

Corollary 13. Let $\nu_* = 2.0316$. For every parameter value $\nu \in [0, \nu_*]$, the Swift-Hohenberg equation (6) is chaotic at the energy level $\mathcal{E} = 0$.

Using the rigorous pseudo-arclength continuation, we also obtained that the branch of periodic solutions we followed has a fold for a parameter value $\nu \in [2.031647, 2.031657]$.
