DISCRETE FUNCTIONAL ANALYSIS TOOLS FOR DISCONTINUOUS GALERKIN METHODS WITH APPLICATION TO THE INCOMPRESSIBLE NAVIER–STOKES EQUATIONS

DANIELE A. DI PIETRO AND ALEXANDRE ERN

ABSTRACT. Two discrete functional analysis tools are established for spaces of piecewise polynomial functions on general meshes: (i) a discrete counterpart of the continuous Sobolev embeddings, in both Hilbertian and non-Hilbertian settings; (ii) a compactness result for bounded sequences in a suitable Discontinuous Galerkin norm, together with a weak convergence property for some discrete gradients. The proofs rely on techniques inspired by the Finite Volume literature, which differ from those commonly used in Finite Element analysis. The discrete functional analysis tools are used to prove the convergence of Discontinuous Galerkin approximations of the steady incompressible Navier–Stokes equations. Two discrete convective trilinear forms are proposed, a nonconservative one relying on Temam’s device to control the kinetic energy balance and a conservative one based on a nonstandard modification of the pressure.

1. Introduction

Discontinuous Galerkin (DG) methods were introduced over thirty years ago to approximate hyperbolic and elliptic PDEs (see e.g. [2, 17] for an historical perspective), and they have received extensive attention over the last decade. For linear PDEs, the mathematical analysis of such methods is well–understood; see e.g. [2] for a unified analysis for the Poisson problem, [15] for advection–diffusion equations with semidefinite diffusion, and [17, 18, 19] for a unified analysis encompassing hyperbolic and elliptic PDEs in the framework of Friedrichs’ systems. The situation is substantially different when dealing with nonlinear second-order PDEs. Indeed, although DG methods have been widely used for such problems, their mathematical analysis has hinged almost exclusively on strong regularity assumptions on the exact solution. This is in stark contrast with the recent literature on Finite Volume (FV) schemes where, following the penetrating works of Eymard, Gallouët, Herbin and co-authors (see e.g. [21, 22, 23]), new discrete functional analysis tools have been derived allowing one to prove the convergence to minimum regularity solutions, i.e. solutions belonging to the natural functional spaces in which the weak formulation of the PDE is set. The key ideas can be summarized as follows:

(i) an a priori estimate on the discrete solution and an associated compactness result are used to infer the strong convergence of a subsequence of discrete solutions to a function $u$ in some Lebesgue space, say $L^2(\Omega)$;

(ii) the construction of a discrete gradient converging to $\nabla u$ in a suitable Lebesgue space allows one to prove that the limit $u$ actually belongs to some space with additional regularity, say $H^1_0(\Omega)$;

(iii) the convergence of the scheme is finally proved testing against the projection of a smooth function belonging to some dense subspace, say $C^\infty_0(\Omega)$.

When the exact solution is unique, the convergence of the whole sequence of discrete approximations is deduced. Moreover, stronger convergence results on the discrete gradient can be derived using the dissipative structure of the problem at hand whenever available.

The present analysis relies on two discrete functional analysis tools in piecewise polynomial spaces on general meshes of a bounded Lipschitz domain $\Omega \subset \mathbb{R}^d$ (DG spaces henceforth). First, upon introducing the usual $\|\cdot\|_{DG}$-norm consisting of the broken gradient plus a jump term (see (5)) as well as non-Hilbertian variants thereof denoted by $\|\cdot\|_{DG,p}$ for $1 \leq p < +\infty$ (see (71)), we prove discrete Sobolev embeddings that are the counterpart of those valid at the continuous level,

$$\|v_h\|_{L^q(\Omega)} \leq \sigma_{p,q} \|v_h\|_{DG,p}, \quad \forall v_h \in V_k^h,$$

for suitable indices $q$ and $p$ and with the DG space $V_k^h$, $k \geq 1$, defined by (4). Probably the best known discrete embedding of such a type is the so-called broken Poincaré–Friedrichs inequality obtained with $p = q = 2$ and valid more generally on a broken Sobolev space; see e.g. [1, 5]. In the Hilbertian case for the DG norm ($p = 2$), broken Sobolev embeddings have been derived recently by Lasis and Suli [29]. We also refer to Karakashian and Jureidini [27] for the case $q = 4$ and $d \in \{2, 3\}$ and to Girault, Rivière, and Wheeler [26] for general $q$ and $d = 2$. An important point is that the present proofs are substantially different from the ones in the finite element literature, which rely on elliptic regularity or on nonconforming finite element interpolants. Indeed, we take inspiration from the techniques used in [22] in the case of piecewise constant functions. A crucial observation is that the BV norm defined in Lemma 6.2 below is controlled by the $\|\cdot\|_{DG}$-norm and also by its non-Hilbertian variants. An important advantage is that the present technique of proof incorporates the use of general, nonconforming polyhedral meshes; that is, under mild assumptions specified below, meshes can possess hanging nodes and consist of elements of various shapes. We only establish the embedding results in DG spaces, and not in the larger setting of broken Sobolev spaces. The latter are indeed not used in the convergence proofs below.

The second functional analysis tool derived herein is a compactness result for bounded sequences in the $\|\cdot\|_{DG}$-norm and its non-Hilbertian versions. Here again, the proof is quite simple and is inspired from [22]: it consists of using Kolmogorov’s Compactness Criterion (see e.g. [7, Theorem IV.25]) based on uniform translate estimates in $L^1(\mathbb{R}^d)$ together with the above discrete Sobolev embeddings and a discrete gradient operator that is shown to be weakly convergent in some $L^p(\Omega)$ space with $p > 1$. Similar results for Sobolev embeddings and compactness of a discrete gradient have been obtained independently by Buffa and Ortner [9].

In the present work we also show how the above analysis tools can be applied to prove the convergence of DG methods under minimal regularity assumptions on the exact solution. In this respect, the weakly consistent discrete gradient operator defined by (12) plays a central role. A further step, going beyond the present scope, could be to consider nonsmooth solutions with localized singularities and
to derive convergence rates for the error away from these singularities. In the present work, we consider the steady incompressible Navier–Stokes equations as a model problem. Various DG approximations of this problem have been investigated recently [3,10,26,27,31]. Here, we identify a set of design conditions on the discrete convective trilinear form to prove convergence. Two discrete convective trilinear forms are proposed, a nonconservative one relying on Temam’s device to control the kinetic energy balance [33] and a conservative one based on a nonstandard modification of the pressure hinted at in [10].

The paper is organized as follows. §2 introduces the discrete setting, including the assumptions on the meshes, the DG spaces, and the discrete gradient operators, whose weak convergence is proven in Theorem 2.2. §3 concerns with the Poisson problem; its purpose is to show how the diffusive term is analyzed. The main result is Theorem 3.1. §4 deals with the Stokes equations; its purpose is to show how the velocity–pressure coupling is handled. The main result is Theorem 4.1. §5 is concerned with the steady incompressible Navier–Stokes equations; its main result is Theorem 5.1. Finally, §6 contains the discrete functional analysis tools in DG spaces. The main results are Theorems 6.1 and 6.3 which are presented in a non-Hilbertian setting since their validity extends beyond the model problems considered in this work.

2. THE DISCRETE SETTING

2.1. Meshes. Let $\Omega$ be an open bounded connected subset of $\mathbb{R}^d$ ($d > 1$) whose boundary $\partial \Omega$ is a finite union of parts of hyperplanes.

**Definition 2.1** (Admissible meshes). Let $\mathcal{H}$ be a countable set. The family $\{T_h\}_{h \in \mathcal{H}}$ is said to be an admissible mesh family if the following assumptions are satisfied:

(i) for all $h \in \mathcal{H}$, $T_h$ is a finite family of nonempty connected (possibly nonconvex) open disjoint sets $T$ forming a partition of $\Omega$ and whose boundaries are a finite union of parts of hyperplanes;

(ii) there is a parameter $N_0$, independent of $h$, such that each $T \in T_h$ has at most $N_0$ faces. A set $F \subset \partial T$ is said to be a face of $T$ if $F$ is part of a hyperplane, and if either $F = \partial T \cap \partial \Omega$ or there is $T' \in T_h, T' \neq T$, such that $F = \partial T \cap \partial T'$;

(iii) there is a parameter $\rho_1$ independent of $h$ such that for all $T \in T_h$,

$$\sum_{F \subset \partial T} h_F |F| \leq \rho_1 |T|,$$

where $h_F$ denotes the diameter of the face $F$, $|F|$ its $(d-1)$-dimensional measure and $|T|$ the $d$-dimensional measure of $T$;

(iv) for all $h \in \mathcal{H}$, each $T \in T_h$ is affine-equivalent to an element belonging to a finite collection of reference elements;

(v) the ratio of the diameter $h_T$ of any $T \in T_h$ to the diameter of the largest ball inscribed in $T$ is bounded from above by a parameter $\rho_2$ independent of $h$;

(vi) there is a parameter $\rho_3$, independent of $h$, such that for all $T \in T_h$ and for all faces $F \subset \partial T$, $h_F \geq \rho_3 h_T$.

For each $h \in \mathcal{H}$, we define $\text{size}(T_h) \overset{\text{def}}{=} \max_{T \in T_h} h_T$. The parameters introduced in the above definition will be referred to as the basic mesh parameters and collectively denoted by the symbol $\mathcal{P}$. 
Remark 2.1. Assumptions (v) and (vi) will not be needed in §6 to prove the discrete Sobolev embeddings nor the weak convergence of discrete gradients.

Figure 1 presents an example of admissible mesh in two space dimensions. The mesh faces are collected in the set $\mathcal{F}_h$. The set $\mathcal{F}_h$ is partitioned into $\mathcal{F}_h^r \cup \mathcal{F}_h^b$, where $\mathcal{F}_h^r$ collects the faces located on $\partial \Omega$, and $\mathcal{F}_h^b$ the remaining ones. For $F \in \mathcal{F}_h^b$, there are $T_1$ and $T_2$ in $\mathcal{T}_h$ such that $F = \partial T_1 \cap \partial T_2$, and we define $\nu_F$ as the unit normal vector to $F$ pointing from $T_1$ to $T_2$. For any function $\varphi$ such that a (possibly two-valued) trace is defined on $F$, let

$$\llbracket \varphi \rrbracket = \varphi|_{T_1} - \varphi|_{T_2}, \quad \{\varphi\} = \frac{1}{2} (\varphi|_{T_1} + \varphi|_{T_2}).$$

For any integer $k \geq 0$ and for all $T \in \mathcal{T}_h$, let $\mathbb{P}_k(T)$ denote the vector space of polynomial functions defined on $T$ with real coefficients and with total degree less than or equal to $k$. Owing to assumptions (iii) and (iv) in Definition 2.1, there is $c_{k, P}$ such that, for all $h \in \mathcal{H}$ and for all $T \in \mathcal{T}_h$,

$$\forall v_h \in \mathbb{P}_k(T), \quad \sum_{F \subseteq \partial T} h_F \int_F |v_h|^2 \leq c_{k, P} \int_T |v_h|^2.$$

Here and in what follows, the symbol $c$ will be used to denote a positive generic constant whose value can change at each occurrence. To keep track of the dependency of such constants on some parameters, subscripts will be used whenever relevant.

2.2. **DG spaces.** Let $k \geq 0$ and consider the finite dimensional space

$$V^k_h \overset{\text{def}}{=} \{ v_h \in L^2(\Omega); \forall T \in \mathcal{T}_h, \ v_h|_T \in \mathbb{P}_k(T) \}.$$

For $k \geq 1$, this space is equipped with the norm

$$\| v_h \|_{\text{DG}}^2 \overset{\text{def}}{=} \sum_{T \in \mathcal{T}_h} \int_T |\nabla v_h|^2 + \sum_{F \in \mathcal{F}_h} \frac{1}{h_F} \int_F \| v_h \|^2,$$

where $|\cdot|$ denotes the Euclidean norm in $\mathbb{R}^d$. For further use, it will be convenient to introduce the seminorms

$$|v_h|_{1, \mathcal{F}, \pm1}^2 \overset{\text{def}}{=} \sum_{F \in \mathcal{F}} h_F^{\pm1} \int_F \| v_h \|^2,$$
where $\mathcal{F}$ is a subset of $\mathcal{F}_h$ that will usually be taken equal to $\mathcal{F}_h$ or to $\mathcal{F}_h^1$. Moreover, we define $\nabla_h v_h$ as the piecewise gradient of $v_h \in V_h^k$, i.e., $\nabla_h v_h \in [V_h^{k-1}]^d$ is such that for all $T \in \mathcal{T}_h$, $\nabla_h v_h|_T = \nabla(v_h|_T)$, so that

$$\|v_h\|_{DG}^2 = \|\nabla_h v_h\|_{L^2(\Omega)^d}^2 + \|v_h\|_{H^1_0(\Omega)}^2. \quad (7)$$

The above norms and seminorms can be extended to $C^{\infty}_c(\Omega) + V_h^k$ (larger spaces are not needed henceforth).

A straightforward but important result concerns the approximability of smooth functions in the $\|\|_{DG}$-norm. For all $l \geq 0$, let $\pi^l_h$ denote the $L^2(\Omega)$-orthogonal projection from $L^2(\Omega)$ onto $V_h^l$. These projectors will also be applied componentwise to vector-valued functions. Let $\varphi \in C^{\infty}_c(\Omega)$. Then, owing to assumptions (ii)–(v) in Definition 2.1 it is clear using classical approximation properties (see e.g. [6][10]) that, for all $l \geq 1$,

$$\|\varphi - \pi^l_h \varphi\|_{DG} \to 0 \quad \text{as} \quad \text{size}(\mathcal{T}_h) \to 0. \quad (8)$$

In what follows, we shall make frequent use of the projector $\pi^l_h$ which will be simply denoted by $\pi_h$.

For ease of exposition, we state Theorem 6.1 in the present Hilbertian setting for the DG norm. A general proof is given in [16].

**Theorem 2.1** (Discrete Sobolev embeddings). For all $q$ such that

(i) $1 \leq q \leq \frac{2d}{d+2}$ if $d \geq 3$,

(ii) $1 \leq q < +\infty$ if $d = 2$,

there is $\sigma_q$ such that

$$\forall v_h \in V_h^k, \quad \|v_h\|_{L^q(\Omega)} \leq \sigma_q \|v_h\|_{DG}. \quad (9)$$

The constant $\sigma_q$ additionally depends on $k$, $|\Omega|$, and $\mathcal{P}$.

2.3. **Discrete gradient operators.** For all $F \in \mathcal{F}_h$, let $r^l_F : L^2(F) \to [V_h^l]^d$, $l \geq 0$, be the lifting operator defined as follows: For all $\phi \in L^2(F)$,

$$\forall \tau_h \in [V_h^l]^d, \quad \int_{\Omega} r^l_F(\phi) : \tau_h = \int_F \tau_h : \nu F \phi. \quad (10)$$

Clearly, the support of $r^l_F(\phi)$ consists of the one or two mesh elements of which $F$ is a face. Now let $k \geq 1$. For $v_h \in V_h^k$, define

$$R^l_F(\|v_h\|) \overset{\text{def}}{=} \sum_{F \in \mathcal{F}_h} r^l_F(\|v_h\|). \quad (11)$$

The following discrete gradient operators $G^l_h : V_h^k \to [V_h^{\max(k-1,l)}]^d$ will play an important role in the analysis:

$$\forall v_h \in V_h^k, \quad G^l_h(v_h) \overset{\text{def}}{=} \nabla_h v_h - R^l_F(\|v_h\|) = \nabla_h v_h - \sum_{F \in \mathcal{F}_h} r^l_F(\|v_h\|). \quad (12)$$

For a given $k \geq 1$, the most natural value for $l$ is $k$ or $(k-1)$, but the values $l = 0$ and $l = 2k$ will also be used. It is straightforward to verify, using assumption (ii) in Definition 2.1 that for all $v_h \in V_h^k$,

$$\|R^l_F(\|v_h\|)\|_{L^2(\Omega)^d}^2 \leq N_0 \sum_{F \in \mathcal{F}_h} \|r^l_F(\|v_h\|)\|_{L^2(\Omega)^d}^2. \quad (13)$$
Furthermore, owing to the trace inequality (3) and proceeding as in (3), it is inferred that for all \( F \in \mathcal{F}_h \),

\[
\|r^F_h(\|v_h\|)\|_{L^2(\Omega)^d} \leq c_{k,l,p} \frac{1}{h_F} \int_F \|v_h\|^2.
\]

As a result,

\[
\|R^F_h(\|v_h\|)\|_{L^2(\Omega)^d} \leq c_{k,l,p} \|v_h\|_{H^{-1}(\Omega)}.
\]

**Proposition 2.1** (Stability of discrete gradients). Let \( k \geq 1 \) and let \( l \geq 0 \). Then,

\[
\forall v_h \in V^k_h, \quad \|G^l_h(v_h)\|_{L^2(\Omega)^d} \leq c_{k,l,p} \|v_h\|_{DG}.
\]

**Proof.** Use the triangle inequality. \( \square \)

**Proposition 2.2** (Strong convergence of discrete gradients for smooth functions). Let \( k \geq 1 \) and let \( l \geq 0 \). For all \( \varphi \in C^\infty_0(\Omega) \), \( G^l_h(\pi_h \varphi) \to \nabla \varphi \) in \( L^2(\Omega)^d \).

**Proof.** Observe that \( \|G^l_h(\pi_h \varphi) - \nabla \varphi\|_{L^2(\Omega)^d} \leq c_{l,p} \|\varphi - \pi_h \varphi\|_{DG} \) and use (3). \( \square \)

The main property of the discrete gradient operators defined by (12) is their weak convergence in \( L^2(\Omega)^d \) when evaluated on bounded sequences in the \( \|\cdot\|_{DG} \)-norm.

**Theorem 2.2** (Compactness and weak convergence of discrete gradients). Let \( k \geq 1 \). Let \( \{v_h\}_{h \in \mathcal{H}} \) be a sequence in \( V^k_h \). Assume that this sequence is bounded in the \( \|\cdot\|_{DG} \)-norm. Then, there exists a function \( v \in H^1_0(\Omega) \) such that as size(\( T_h \)) \to 0, up to a subsequence, \( v_h \to v \) strongly in \( L^2(\Omega) \) and for all \( l \geq 0 \), \( G^l_h(v_h) \to \nabla v \) weakly in \( L^2(\Omega)^d \).

**Proof.** Owing to Theorem 2.2 applied with \( p = 2 \) and extending the functions \( v_h \) by zero outside \( \Omega \), there exists a function \( v \in L^2(\mathbb{R}^d) \) such that as size(\( T_h \)) \to 0, up to a subsequence, \( v_h \to v \) strongly in \( L^2(\mathbb{R}^d) \). Moreover, since for all \( l \geq 0 \), \( \{G^l_h(v_h)\}_{h \in \mathcal{H}} \) is bounded in \( L^2(\mathbb{R}^d)^d \) owing to Proposition 2.1 up to a new subsequence, there is \( w \in L^2(\mathbb{R}^d)^d \) s.t. \( G^l_h(v_h) \to w \) weakly in \( L^2(\mathbb{R}^d)^d \). To prove that \( w = \nabla v \), let \( \varphi \in C^\infty_0(\mathbb{R}^d) \) and observe that

\[
\int_{\mathbb{R}^d} G^l_h(v_h) \cdot \varphi = -\int_{\mathbb{R}^d} v_h(\nabla \cdot \varphi) - \int_{\mathbb{R}^d} R^l_h(\|v_h\|) \cdot (\varphi - \pi^0_h \varphi) + \sum_{F \in \mathcal{F}_h} \int_F \|\varphi - \pi^0_h \varphi\|_{DG} \cdot v_F \|v_h\| = T_1 + T_2 + T_3.
\]

Letting size(\( T_h \)) \to 0, we observe that \( T_1 \to -\int_{\mathbb{R}^d} v(\nabla \cdot \varphi) \) and that \( T_2 \to 0 \) since \( \|\varphi - \pi^0_h \varphi\|_{L^2(\mathbb{R}^d)^d} \to 0 \) and \( \{R^l_h(\|v_h\|)\}_{h \in \mathcal{H}} \) is bounded in \( L^2(\mathbb{R}^d)^d \). Furthermore, the Cauchy–Schwarz inequality, together with assumption (iii) in Definition 2.1 yields

\[
|T_3| \leq C \|\varphi - \pi^0_h \varphi\|_{L^\infty(\mathbb{R}^d)^d} \|v_h\|_{L^2(\mathcal{F}_h)} \leq C' \|\varphi - \pi^0_h \varphi\|_{L^\infty(\mathbb{R}^d)^d},
\]

which tends to zero as size(\( T_h \)) \to 0. As a result,

\[
\int_{\mathbb{R}^d} w \cdot \varphi = \lim_{\text{size}(T_h) \to 0} \int_{\mathbb{R}^d} G^l_h(v_h) \cdot \varphi = -\int_{\mathbb{R}^d} v(\nabla \cdot \varphi),
\]

implying that \( w = \nabla v \). Hence, \( v \in H^1(\mathbb{R}^d) \) and since \( v \) is zero outside \( \Omega \), \( v \) is in \( H^1_0(\Omega) \). \( \square \)
The weak formulation of this problem consists of finding \( v_h \in V_h^k \) s.t.
\[
\forall v_h \in V_h^k, \quad G_h(v_h) \overset{\text{def}}{=} \nabla_h v_h - \sum_{F \in F_h^k} r_F^l([v_h]).
\]

The difference with respect to the discrete gradient operator \( G_h^l \) defined by (12) is that boundary faces are not included in (17). The discrete gradient operator \( G_h^l \) also satisfies the conclusions of Propositions 2.1 and 2.2. More importantly, it also satisfies the conclusions of Theorem 2.2. This is so because \( \varphi \) in the above proof is compactly supported; hence, as \( \text{size}(T_h) \to 0 \), the mesh becomes fine enough so that all the mesh elements having a boundary face are located outside the support of \( \varphi \).

3. The Poisson problem

Let \( f \in L^r(\Omega) \) with \( r = \frac{2d}{d+2} \) if \( d \geq 3 \) and \( r > 1 \) if \( d = 2 \). Set \( r' \overset{\text{def}}{=} \frac{r}{r-1} \). Consider the following model problem
\[
\begin{cases}
-\Delta u = f, & \text{in } \Omega, \\
u = 0, & \text{on } \partial\Omega.
\end{cases}
\]

The weak formulation of this problem consists of finding \( u \in H^1_0(\Omega) \) s.t. for all \( v \in H^1_0(\Omega) \),
\[
\int_{\Omega} \nabla u \cdot \nabla v = \int_{\Omega} f v.
\]

It is well known that this problem is well-posed. In particular, owing to the Sobolev embedding \( \|v\|_{L^r(\Omega)} \leq S_{2,r'} \|\nabla v\|_{L^2(\Omega)^d} \) valid for all \( v \in H^1_0(\Omega) \), and using Hölder’s inequality, it is inferred that
\[
\|\nabla v\|_{L^2(\Omega)^d}^2 = \int_{\Omega} f u \leq \|f\|_{L^r(\Omega)} \|u\|_{L^{r'}(\Omega)} \leq S_{2,r'} \|f\|_{L^r(\Omega)} \|\nabla v\|_{L^2(\Omega)^d},
\]
yielding the a priori bound \( \|\nabla u\|_{L^2(\Omega)^d} \leq S_{2,r'} \|f\|_{L^r(\Omega)} \).

3.1. Symmetric formulations. Let \( k \geq 1 \). For the sake of simplicity, discrete gradients are built using the lifting operators \( r_F^l \) (see Remark 3.2 below for further discussion) and to alleviate the notation, the superscript \( k \) is omitted. This convention is kept for the rest of this work. For all \( (v_h, w_h) \in V_h \times V_h \), consider the following symmetric DG bilinear form
\[
a_h(v_h, w_h) \overset{\text{def}}{=} \int_{\Omega} G_h(v_h) \cdot G_h(w_h) + j_h(v_h, w_h),
\]
with the stabilization bilinear form
\[
j_h(v_h, w_h) \overset{\text{def}}{=} \sum_{F \in F_h} \eta \int_{F} r_F([v_h]) \cdot r_F([w_h]) - \int_{\Omega} R_h([v_h]) \cdot R_h([w_h]),
\]
where \( \eta \in \mathbb{R}_+ \) is a penalty parameter. Henceforth, we assume that
\[
\eta > N_\partial.
\]
Observe that for all \( v_h \in V_h \), (13) yields
\[
\|G_h(v_h)\|_{L^2(\Omega)^d}^2 + (\eta - N_\partial) \sum_{F \in F_h} \|r_F([v_h])\|_{L^2(\Omega)^d}^2 \leq a_h(v_h, v_h).
\]
Remark 3.1. The bilinear forms $a_h$ and $j_h$ can also be written without using lifting operators. We use explicitly the discrete gradient operator $G_h$ since it plays a central role in the convergence proof. A straightforward calculation shows that

$$a_h(v_h, w_h) = \int_\Omega \nabla_h v_h \cdot \nabla_h w_h - \sum_{F \in \mathcal{T}_h} 2 \left( \nu_F \cdot \nabla_h v_h \right) \cdot \left( \nu_F \cdot \nabla_h w_h \right) + \nu_F \cdot \nabla_h w_h \cdot \nabla_h v_h \right) \right)$$

(25)

$$+ \sum_{F \in \mathcal{T}_h} \eta \int_\Omega r_F(\|v_h\|) \cdot r_F(\|w_h\|),$$

yielding the IP-type method introduced in [4]. Other stabilizations are possible. In particular,

$$j_h^{\text{SIPG}}(v_h, w_h) \overset{\text{def}}{=} \sum_{F \in \mathcal{T}_h} \eta \frac{1}{h_F} \int_F \|v_h\| \|w_h\| - \int_\Omega R_h(\|v_h\|) \cdot R_h(\|w_h\|),$$

yielding the usual Symmetric Interior Penalty method (SIPG) [1]. In this case, the minimal threshold for the penalty parameter $\eta$ depends on the constant in the trace inequality (3). It is also possible to consider the stabilization

$$j_h^{\text{LDG}}(v_h, w_h) \overset{\text{def}}{=} \sum_{F \in \mathcal{T}_h} \eta \frac{1}{h_F} \int_F \|v_h\| \|w_h\|,$$

yielding one version of the Local Discontinuous Galerkin method (LDG) [12]. The advantage is that the parameter $\eta$ needs only to be positive, but the stencil is enlarged to neighbors of neighbors. Moreover, working with any of the two above stabilization bilinear forms allows one to omit assumption (vi) in Definition 2.1.

Lemma 3.1 (Coercivity). There is $\alpha > 0$, depending on $\eta$, $k$, and $\mathcal{P}$ such that for all $v_h \in V_h^k$,

$$\alpha \|v_h\|_{DG}^2 \leq a_h(v_h, v_h).$$

(26)

Proof. Proceeding as in [8] using assumptions (iv) and (vi) in Definition 2.1 yields for all $F \in \mathcal{T}_h$,

$$\frac{1}{h_F} \int_F \|v_h\|^2 \leq c_{k, F} \|v_h\|_{L^2(\Omega)}^2.$$

(27)

Using the triangle inequality, it is then inferred that

$$\|v_h\|_{DG}^2 \leq 2 \|G_h(v_h)\|_{L^2(\Omega)}^2 + 2 \|R_h(\|v_h\|)\|_{L^2(\Omega)}^2 + |v_h|_{l, \mathcal{T}_h, -1}^2$$

$$\leq 2 \|G_h(v_h)\|_{L^2(\Omega)}^2 + (2N_\delta + c'_{k, F}) \sum_{F \in \mathcal{T}_h} \|r_F(\|v_h\|)\|_{L^2(\Omega)}^2$$

$$\leq \max(2, (2N_\delta + c'_{k, F})(\eta - N_\delta)^{-1}) a_h(v_h, v_h),$$

the last inequality resulting from (24). □

Remark 3.2. Coercivity also holds if the stabilization bilinear form $j_h$ is defined using liftings of degree $< k$. In this case, the upper bound in (27) also contains the $L^2(\Omega)^d$-norm of the broken gradient.

For all $h \in \mathcal{H}$, Lemma 3.1 implies that there is a unique $u_h \in V_h^k$ s.t.

$$a_h(u_h, v_h) = \int_\Omega f v_h, \quad \forall v_h \in V_h^k.$$

(28)
**Theorem 3.1** (Convergence for the Poisson problem). Let \( \{u_h\}_{h \in H} \) be the sequence of approximate solutions generated by solving the discrete problems (28) on the admissible meshes \( \{T_h\}_{h \in H} \). Then, as \( \text{size}(T_h) \to 0 \),

\[
\begin{align*}
(29) & \quad u_h \to u, \quad \text{in } L^2(\Omega), \\
(30) & \quad \nabla_h u_h \to \nabla u, \quad \text{in } L^2(\Omega)^d, \\
(31) & \quad |u_h|_{1,F_{h,-1}} \to 0,
\end{align*}
\]

where \( u \in H^1_0(\Omega) \) is the unique solution to (18).

**Proof.** (i) A priori estimate. Using Lemma 3.1 and Hölder’s inequality, it is inferred that

\[
\alpha \|u_h\|^2_{DG} \leq a(u_h,u_h) = \int_\Omega f u_h \leq \|f\|_{L^r(\Omega)} \|u_h\|_{L^r(\Omega)}.
\]

Hence, owing to Theorem 2.1, the sequence \( \{u_h\}_{h \in H} \) is bounded in the \( \|\cdot\|_{DG} \)-norm.

(ii) \( L^2 \)-convergence of a subsequence, regularity of the limit and weak convergence of discrete gradient. Owing to Theorem 2.2, there exists \( u \in H^1_0(\Omega) \) such that, as \( \text{size}(T_h) \to 0 \), up to a subsequence, \( u_h \to u \) strongly in \( L^2(\Omega) \) and \( G_h(u_h) \to \nabla u \) weakly in \( L^2(\Omega)^d \).

(iii) Identification of \( u \) and convergence of the whole sequence. Let us first prove that for all \( \varphi \in C^\infty_c(\Omega) \),

\[
(32) \quad a_h(u_h,\pi_h \varphi) \to \int_\Omega \nabla u \cdot \nabla \varphi.
\]

Indeed, observe that

\[
a_h(u_h,\pi_h \varphi) = \int_\Omega G_h(u_h)G_h(\pi_h \varphi) + j_h(u_h,\pi_h \varphi) = T_1 + T_2.
\]

Clearly, \( T_1 \to \int_\Omega \nabla u \cdot \nabla \varphi \) owing to the weak convergence of \( G_h(u_h) \) and the strong convergence of \( G_h(\pi_h \varphi) \) (see Proposition 2.2). Furthermore, \( T_2 \to 0 \) since \( T_2 \) is controlled by \( |u_h|_{1,F_{h,-1}}|\pi_h \varphi|_{1,F_{h,-1}} \) where the first factor is bounded and the second tends to zero. A direct consequence of (32) is that for all \( \varphi \in C^\infty_c(\Omega) \),

\[
\int_\Omega f \varphi \leftarrow \int_\Omega f \pi_h \varphi = a_h(u_h,\pi_h \varphi) \to \int_\Omega \nabla u \cdot \nabla \varphi.
\]

Thus, \( u \) solves the Poisson problem by density of \( C^\infty_c(\Omega) \) in \( H^1_0(\Omega) \). Since the solution of this problem is unique, the whole sequence \( \{u_h\}_{h \in H} \) strongly converges to \( u \) in \( L^2(\Omega) \) and \( \{G_h(u_h)\}_{h \in H} \) weakly converges to \( \nabla u \) in \( L^2(\Omega)^d \).

(iv) Strong convergence of the discrete gradient and of the jumps. Owing to (24) and to weak convergence,

\[
\liminf a_h(u_h,u_h) \geq \liminf \|G_h(u_h)\|^2_{L^2(\Omega)^d} \geq \|\nabla u\|^2_{L^2(\Omega)^d}.
\]

Furthermore, still owing to (24),

\[
\|G_h(u_h)\|^2_{L^2(\Omega)^d} \leq a_h(u_h,u_h) = \int_\Omega f u_h,
\]

yielding

\[
\limsup \|G_h(u_h)\|^2_{L^2(\Omega)^d} \leq \limsup a_h(u_h,u_h) = \limsup \int_\Omega f u_h = \int_\Omega f u = \|\nabla u\|^2_{L^2(\Omega)^d}.
\]
Thus, \( \| G_h(u_h) \|_{L^2(\Omega)^d} \to \| \nabla u \|_{L^2(\Omega)^d} \), classically yielding the strong convergence of the discrete gradient in \( L^2(\Omega)^d \). Note that \( a_h(u_h, u_h) \to \| \nabla u \|_{L^2(\Omega)^d}^2 \) also. Finally, owing to (24),
\[
(\eta - N_\theta) \sum_{F \in F_h} \| r_F([u_h]) \|_{L^2(\Omega)^d}^2 \leq a_h(u_h, u_h) - \| G_h(u_h) \|_{L^2(\Omega)^d}^2,
\]
and since \( \eta > N_\theta \) and the right-hand side tends to zero, it is inferred using (27) that \( |u_h|_{1, F_{h,-1}} \to 0 \). Moreover, using (13) to estimate the second term yields
\[
\| \nabla u_h - \nabla u \|_{L^2(\Omega)^d} \leq \| G_h(u_h) - \nabla u \|_{L^2(\Omega)^d} + \| R_h(u_h) \|_{L^2(\Omega)^d} \to 0,
\]
as \( h \to 0 \), concluding the proof. \[ \square \]

**Remark 3.3**. We emphasize that the discrete bilinear forms \( a_h \) and \( j_h \) are only defined at the discrete level. Thus, the consistency of the method is expressed by the property (32), and not by inserting the exact solution into the bilinear form as is the case in the usual finite element analysis. To proceed in the usual way, the bilinear forms \( a_h \) and \( j_h \) must first be extended to a larger functional space, and the two strictly equivalent expressions for \( a_h \) at the discrete level, namely (21) and (25), do not lead to the same extension, and only the form using discrete gradients can be extended up to \( H^1(\Omega) \). If the discrete gradients are kept, the extended bilinear form is weakly consistent since for \( u \) smooth enough and for all \( v_h \in V_h^k \),
\[
a_h(u_h - u, v_h) = \sum_{F \in F_h} \int_F \nu_F \| \pi_h^k(\nabla u) - \nabla u \| \|[v_h]\|.
\]
If the equivalent expression (25) is used, the extended bilinear form is strongly consistent if the exact solution is in \( H^{3/2+\epsilon}(T_h) \), \( \epsilon > 0 \). In both cases, standard finite element techniques lead to the optimally convergent error bound \( \| u - u_h \|_{DG} \leq c_n \text{size}(T_h)^k \) when \( u \in H^{k+1}(T_h) \).

**3.2. Nonsymmetric formulations.** Nonsymmetric DG approximations to the Poisson problem (and other selfadjoint PDEs) have received some interest in the literature. Such formulations use a nonsymmetric bilinear form that can be cast into the generic form
\[
a_h(v_h, w_h) = \int_\Omega \hat{G}_h(v_h) \cdot G_h(w_h) + j_h(v_h, w_h),
\]
where \( G_h \) is the discrete gradient considered above, whereas the discrete gradient \( \hat{G}_h \) and the stabilization bilinear form \( j_h \) must satisfy the following design conditions:

**NS1**  Stability of the discrete gradient \( \hat{G}_h \): there is \( c \) s.t., for all \( v_h \in V_h^k \),
\[
\| \hat{G}_h(v_h) \|_{L^2(\Omega)^d} \leq c \| v_h \|_{DG}.
\]

**NS2**  Strong convergence of the discrete gradient \( \hat{G}_h \) for smooth functions: for all \( \varphi \in C^\infty_0(\Omega) \), \( \hat{G}_h(\pi_h \varphi) \to \nabla \varphi \) in \( L^2(\Omega)^d \).

**NS3**  Stabilization: the bilinear form \( j_h \) is symmetric and positive, and there is \( c \) s.t. for all \( v_h \in V_h^k \), \( j_h(v_h, v_h) \leq c \| v_h \|_{L^2(\Omega)^d}^2 \) (so that for all \( (v_h, w_h) \in V_h^k \times V_h^k \), \( j_h(v_h, w_h) \leq c \| v_h \|_{L^2(\Omega)^d} \| w_h \|_{L^2(\Omega)^d} \)).

**NS4**  Coercivity: there is \( \eta_\ast > 0 \) such that for all \( v_h \in V_h^k \),
\[
a_h(v_h, v_h) \geq \eta_\ast \| v_h \|^2_{DG}.
\]
Coercivity implies that the discrete problem (28) is well-posed.
Under the above assumptions, the convergence of the sequence of discrete DG approximations can be proven. The proof, however, proceeds along a slightly different path with respect to the symmetric formulation.

**Theorem 3.2.** Let \( \{ u_h \}_{h \in \mathcal{H}} \) be the sequence of approximate solutions generated by solving the discrete problems (28) with the bilinear form \( a_h \) given by (33) on the admissible meshes \( \{ T_h \}_{h \in \mathcal{H}} \). Assume that the design conditions (N1)–(N4) hold. Then, as \( \text{size}(T_h) \to 0 \), \( u_h \to u \) in \( L^2(\Omega) \) and \( \nabla u \to \nabla u \) in \( L^2(\Omega)^d \), where \( u \in H^1_0(\Omega) \) is the unique solution to (15).

**Proof.** (i) Proceeding as before, it is inferred from (N1) that the sequence \( \{ u_h \}_{h \in \mathcal{H}} \) is bounded in the \( \| \cdot \|_{DG} \)-norm, so that there exists \( u \in H^1_0(\Omega) \) such that, up to a subsequence, \( u_h \rightharpoonup u \) in \( L^2(\Omega) \) and \( \nabla u \rightharpoonup \nabla u \) in \( L^2(\Omega)^d \) as \( \text{size}(T_h) \to 0 \).

(ii) Strong convergence of \( \nabla u \). Let \( \varphi \in C_c^\infty(\Omega) \). Observe that

\[
\frac{1}{2} \| \nabla u \|_{L^2(\Omega)^d}^2 \leq \| \nabla u \|_{L^2(\Omega)^d}^2 + \| \varphi \|_{L^2(\Omega)^d}^2 \quad \text{for all } (n, s) = (1, 4) \text{ to infer that}
\]

\[
T_1 = \| \nabla u \|_{L^2(\Omega)^d}^2 \leq \frac{\varepsilon}{\varepsilon_0} a_h(u_h - \pi_h \varphi, u_h - \pi_h \varphi)
= \frac{\varepsilon}{\varepsilon_0} \left( \int_\Omega f(u_h - \pi_h \varphi) - a_h(u_h, u_h - \pi_h \varphi) \right)
= \frac{\varepsilon}{\varepsilon_0} (T_{1,1} - T_{1,2}).
\]

Clearly, as \( \text{size}(T_h) \to 0 \), \( T_{1,1} \to \int_\Omega f(u - \varphi) \). Moreover, by definition,

\[
T_{1,2} = \int_\Omega (\nabla u \cdot \nabla \pi_h \varphi) \quad \text{for all } (n, s) = (1, 4) \text{ to infer that}
\]

\[
T_{1,2} = \int_\Omega (\nabla u \cdot \nabla \pi_h \varphi) \quad \text{for all } (n, s) = (1, 4) \text{ to infer that}
\]

\[
\limsup \| \nabla u \|_{L^2(\Omega)^d}^2 \leq C \| u - \varphi \|_{H^1(\Omega)}^2.
\]

Using the density of \( C_c^\infty(\Omega) \) in \( H^1_0(\Omega) \), this upper bound can be made as small as desired. This proves the strong convergence of \( \nabla u \) to \( \nabla u \) in \( L^2(\Omega)^d \).

(iii) Identification of the limit and convergence of the whole sequence. Let \( \varphi \in C_c^\infty(\Omega) \). It is clear that as \( \text{size}(T_h) \to 0 \), \( \int_\Omega f \pi_h \varphi \to \int_\Omega f \varphi \). Furthermore,

\[
a_h(u_h, \pi_h \varphi) = \int_\Omega \nabla u_h \cdot \nabla \pi_h \varphi + j'_h(u_h, \pi_h \varphi) = T_3 + T_4.
\]

Clearly, \( T_3 \to \int_\Omega \nabla u \cdot \nabla \varphi \). In addition, \( T_4 \) converges to zero since it is bounded by \( |u_h|_{1, F, s, -1} |\pi_h \varphi|_{1, F, s, -1} \cdot \). As a result,

\[
\int_\Omega f \varphi \leftarrow \int_\Omega f \pi_h \varphi = a_h(u_h, \pi_h \varphi) \to \int_\Omega \nabla u \cdot \nabla \varphi.
\]

The proof can now be concluded as in the symmetric case. \( \square \)
Classical examples of the situation analyzed by Theorem 3.2 are the so-called Incomplete Interior Penalty method (IIPG) for which
\begin{equation}
\hat{G}_h(v_h) = \nabla_h v_h,
\end{equation}
and the so-called Nonsymmetric Interior Penalty method (NIPG) for which
\begin{equation}
\hat{G}_h(v_h) = \nabla_h v_h + R_h([v_h]).
\end{equation}

4. The Stokes equations

Let \( f \in L^r(\Omega)^d \) with \( r = \frac{2d}{d+2} \) if \( d \geq 3 \) and \( r > 1 \) if \( d = 2 \). Let \( \nu > 0 \). The components in the Cartesian basis \( (e_1, \ldots, e_d) \) of \( \mathbb{R}^d \) of a function, say \( v \), with values in \( \mathbb{R}^d \) will be denoted by \( (v_i)_{1 \leq i \leq d} \). Implicit summation convention of repeated indices is adopted henceforth. Consider the Stokes equations
\begin{equation}
\begin{aligned}
-\nu \Delta u_i + \partial_i p &= f_i, & \text{in } \Omega, & i \in \{1, \ldots, d\}, \\
\partial_i u_i &= 0, & \text{in } \Omega, \\
\nu c u_i &= 0, & \text{on } \partial \Omega, \\
\int_\Omega p &= 0.
\end{aligned}
\end{equation}

The weak formulation of this system consists of finding \((u, p) \in H^1_0(\Omega)^d \times L^2_0(\Omega)\) s.t. for all \((v, q) \in H^1_0(\Omega)^d \times L^2_0(\Omega)\),
\begin{equation}
\begin{aligned}
\nu \int_\Omega \partial_j u_i \partial_j v_i - \int_\Omega p \partial_i v_i + \int_\Omega q \partial_i u_i &= \int_\Omega f_i v_i.
\end{aligned}
\end{equation}

The well–posedness of the above problem is a classical result (see e.g. [16] and references therein).

To formulate a DG approximation, we consider for each component of the velocity the symmetric DG bilinear form \( a_h \) defined by (21) and the stabilization bilinear form \( j_h \) defined by (22). For the sake of simplicity, in particular with an eye towards ease of implementation, we will consider the case of equal-order polynomial interpolation for the velocity and for the pressure. Letting \( k \geq 1 \), we thus set
\begin{equation}
U_h \overset{\text{def}}{=} [V^k_h]^{d}, \quad P_h \overset{\text{def}}{=} V^k_h / \mathbb{R}, \quad X_h \overset{\text{def}}{=} U_h \times P_h.
\end{equation}

For \( \mathbb{R}^d \)-valued functions such as velocities, the seminorm \( \| \cdot \|_{1, X_h, -1} \) and the norm \( \| \cdot \|_{\text{DG}} \) are defined as the square root of the sum of the squares of the corresponding seminorm or norm for all the components.

4.1. Discrete divergence operators. Define on \( U_h \times P_h \) the bilinear form
\begin{equation}
b_h(v_h, q_h) \overset{\text{def}}{=} \int_\Omega v_h \nabla_h q_h - \sum_{F \in F_h^\text{int}} \int_F \nu_F \cdot \{ v_h \} \{ q_h \}.
\end{equation}

Integration by parts readily yields the following equivalent expression
\begin{equation}
b_h(v_h, q_h) = -\int_\Omega q_h \nabla_h \cdot v_h + \sum_{F \in F_h^\text{int}} \int_F \nu_F \cdot \{ v_h \} \{ q_h \}.
\end{equation}

Here, \( \nabla_h \cdot \) denotes the broken divergence operator acting elementwise. Furthermore, define on \( P_h \times P_h \) the pressure stabilization bilinear form
\begin{equation}
s_h(q_h, r_h) \overset{\text{def}}{=} \sum_{F \in F_h^\text{int}} \gamma_h_F \int_F \{ q_h \} \{ r_h \}.
\end{equation}
Here, $\gamma \in \mathbb{R}_+$ is a penalty parameter. For simplicity, it will be taken equal to 1 in what follows. The basic stability result for the bilinear form $b_h$ is the following.

**Lemma 4.1.** There is $\beta > 0$, depending on $\Omega$, $k$, and $\mathcal{P}$, such that

\begin{equation}
\forall q_h \in P_h, \quad \beta \|q_h\|_{L^2(\Omega)} \leq \sup_{0 \neq v_h \in U_h} \frac{b_h(v_h,q_h)}{\|v_h\|_{\text{DG}}} + |q_h|_{L^2_{\gamma,1}}.
\end{equation}

**Proof.** Let $q_h \in P_h$. Owing to a result by Nečas [32], there is $v \in H^1_0(\Omega)^d$ s.t. $\nabla \cdot v = q_h$ and $\|v\|_{H^1(\Omega)^d} \leq c_2 \|q_h\|_{L^2(\Omega)}$. Then,

\begin{align*}
\|q_h\|^2_{L^2(\Omega)} &= \int_\Omega q_h (\nabla \cdot v) = -\int_\Omega \nabla h q_h \cdot v + \sum_{F \in \mathcal{F}_h} \int_F [q_h] [v] \cdot \nu_F \\
&= -\int_\Omega \nabla h q_h \cdot \pi_h^k v + \sum_{F \in \mathcal{F}_h} \int_F [q_h] [v] \cdot \nu_F \\
&= -b_h(\pi_h^k v, q_h) + \sum_{F \in \mathcal{F}_h} \int_F [q_h] [v - \pi_h^k v] \cdot \nu_F \\
&= T_1 + T_2.
\end{align*}

Since $\|\pi_h^k v\|_{\text{DG}} \leq c_{k,\mathcal{P}} \|v\|_{H^1(\Omega)^d} \leq c_{\Omega, k, \mathcal{P}} \|q_h\|_{L^2(\Omega)}$, it is inferred that

\begin{equation}
|T_1| \leq \frac{|b_h(\pi_h^k v, q_h)|}{\|\pi_h^k v\|_{\text{DG}}} \leq c_{\Omega, k, \mathcal{P}} \left( \sup_{0 \neq v_h \in U_h} \frac{b_h(v_h,q_h)}{\|v_h\|_{\text{DG}}} \right) \|q_h\|_{L^2(\Omega)}.
\end{equation}

Similarly, using assumption (vi) in Definition 2.1, $|T_2| \leq c_{\Omega, k, \mathcal{P}} |q_h|_{L^2_{\gamma,1}} \|q_h\|_{L^2(\Omega)}$, whence the conclusion follows. \hfill \Box

**Remark 4.1.** A more easily computable form for the pressure penalty term can be obtained by replacing $h_F$ with the quantity $\frac{\|T_1\|}{|T_2|}$ in (41) and redefining the seminorm $|\cdot|_{L^2_{\gamma,1}}$ accordingly.

Recall the discrete gradient operators $G^l_h$ and $G_l^j$ defined in [2,3]. For all $l \geq 0$, introduce now the discrete divergence operators $D^l_h : U_h \to V_h^{\max(k-1,l)}$ defined s.t.

\begin{equation}
\forall v_h \in U_h, \quad D^l_h(v_h) \overset{\text{def}}{=} G^l_h(v_h) \cdot e_j.
\end{equation}

For $l \geq k$, the following integration by parts formula holds for all $(v_h,q_h) \in X_h$:

\begin{equation}
\int_\Omega q_h D^l_h(v_h) + \int_\Omega G^l_h(q_h) \cdot v_h = 0.
\end{equation}

Moreover, it is easily seen that for $l \geq k$ and for all $(v_h,q_h) \in X_h$,

\begin{equation}
b_h(v_h,q_h) = \int_\Omega v_h G^l_h(q_h) = -\int_\Omega q_h D^l_h(v_h).
\end{equation}

As before, superscripts will be dropped if $l = k$. 

License or copyright restrictions may apply to redistribution; see http://www.ams.org/journal-terms-of-use
4.2. Stability estimates and discrete well–posedness. Define for all \(((u_h, p_h), (v_h, q_h)) \in X_h \times X_h\), the bilinear form

\[
l_h((u_h, p_h), (v_h, q_h)) = \int_{\Omega} f_i v_{h, i}, \quad \forall (v_h, q_h) \in X_h.
\]

The discrete Stokes equations consist in finding \((u_h, p_h) \in X_h\) s.t.

\[
l_h((u_h, p_h), (v_h, q_h)) = \int_{\Omega} f_i v_{h, i}, \quad \forall (v_h, q_h) \in X_h.
\]

Define the following norm:

\[
\|v_h, q_h\|^2_S \overset{\text{def}}{=} \|v_h\|_{DG}^2 + \|q_h\|_{J,F_h^\text{Dup}}^2 + \|q_h\|_{L^2(\Omega)}^2.
\]

A direct consequence of (29) applied componentwise is the following result:

**Lemma 4.2.** Let \(\alpha > 0\) be as in Lemma 3.1. Then, the following holds:

\[
\forall (v_h, q_h) \in X_h, \quad \alpha \|v_h\|_{DG}^2 + \|q_h\|_{J,F_h^\text{Dup}}^2 + \|q_h\|_{L^2(\Omega)}^2 \leq l_h((v_h, q_h), (v_h, q_h)).
\]

Combining Lemmas 4.1 and 4.2 classically yields the following stability result.

**Lemma 4.3.** There is \(c_I > 0\) depending on \(\nu, k, P, \Omega, \) and \(\eta\) s.t.

\[
\forall (v_h, q_h) \in X_h, \quad c_I \|(v_h, q_h)\|_S \leq \sup_{0 \neq (w_h, r_h) \in X_h} \frac{l_h((v_h, q_h), (w_h, r_h))}{\|(w_h, r_h)\|_S}.
\]

A direct consequence of Lemma 4.3 is that for all \(h \in H\), the discrete problem (47) admits a unique solution \((u_h, p_h) \in X_h\).

4.3. Convergence analysis. In this section, we are now interested in the convergence of the sequence \(\{(u_h, p_h)\}_{h \in H}\) of solutions to the discrete Stokes equations (47) towards the unique solution \((u, p)\) of the continuous Stokes equations (37).

**Theorem 4.1** (Convergence for Stokes equations). Let \(\{(u_h, p_h)\}_{h \in H}\) be the sequence of approximate solutions generated by solving the discrete problems (47) on the admissible meshes \(\{T_h\}_{h \in H}\). Then, as size\((T_h) \to 0\),

\[
\begin{align*}
&u_h \to u, \quad \text{in } L^2(\Omega), \\
&\nabla u_h \to \nabla u, \quad \text{in } L^2(\Omega), \\
&|u_h|_{J,F_h^\text{Dup}} \to 0, \\
&p_h \to p, \quad \text{in } L^2(\Omega), \\
&|p_h|_{J,F_h^\text{Dup}} \to 0,
\end{align*}
\]

where \((u, p) \in H_0^1(\Omega) \times L^2_0(\Omega)\) is the unique solution to (37).

**Proof.** (i) A priori estimates. Owing to the inf-sup condition (50), the assumption on \(f\), and the discrete Sobolev embedding, the sequence \(\{(u_h, p_h)\}_{h \in H}\) is bounded in the \(\|\cdot\|_S\)-norm. Hence, up to a subsequence, there is \((u, p) \in H^1_0(\Omega) \times L^2_0(\Omega)\) s.t.

\[u_h \to u\text{ strongly in } L^2(\Omega), \quad G_h(u_h, i) \to \nabla u_i \text{ weakly in } L^2(\Omega) \text{ for all } i \in \{1, \ldots, d\}, \]

\[p_h \to p\text{ weakly in } L^2(\Omega).
\]

(ii) Identification of the limit and convergence of the whole sequence. Let \(\varphi \in C^\infty_c(\Omega)^d\). Testing with \((\pi_h \varphi, 0)\) yields

\[
\nu a_h(u_{h, i}, \pi_h \varphi_i) + b_h(\pi_h \varphi, p_h) = \int_{\Omega} f_i \pi_h \varphi_i.
\]
Clearly, as size($T_h$) → 0, the right-hand side tends to $\int_{\Omega} f_i \varphi_i$. Furthermore, proceeding as for the Poisson problem yields that the first term in the left-hand side converges to $\nu \int_{\Omega} \partial_j u_i \partial_j \varphi_i$. Consider now the second term and observe using (15) that $b_h(\pi_h \varphi, p_h) = -\int_{\Omega} p_h D_h(\pi_h \varphi)$. Owing to the weak convergence of $\{p_h\}_{h \in \mathcal{H}}$ to $p$ in $L^2(\Omega)$ and the strong convergence of $\{D_h(\pi_h \varphi)\}_{h \in \mathcal{H}}$ to $\nabla \cdot \varphi$ in $L^2(\Omega)$, $b_h(\pi_h \varphi, p_h)$ tends to $-\int_{\Omega} p(\nabla \cdot \varphi)$. As a result,

$$
\nu \int_{\Omega} \partial_j u_i \partial_j \varphi_i - \int_{\Omega} p \partial_j \varphi_j = \int_{\Omega} f_i \varphi_i.
$$

Let now $\psi \in C_c^\infty(\Omega)/\mathbb{R}$. Testing with $(0, \pi_h \psi)$ yields

$$
-b_h(u_h, \pi_h \psi) + s_h(p_h, \pi_h \psi) = 0.
$$

Clearly, $-b_h(u_h, \pi_h \psi) = \int_{\Omega} \pi_h \psi D_h(u_h)$ tends to $\int_{\Omega} \psi (\nabla \cdot u)$ since $\{D_h(u_h)\}_{h \in \mathcal{H}}$ weakly converges to $\nabla \cdot u$ in $L^2(\Omega)$ and $\{\pi_h \psi\}_{h \in \mathcal{H}}$ strongly converges to $\psi$ in $L^2(\Omega)$. Furthermore, $s_h(p_h, \pi_h \psi)$ tends to zero since $|s_h(p_h, \pi_h \psi)| \leq |p_h|_{1,J_h,1} |\pi_h \psi|_{1,J_h,1} \leq C |\pi_h \psi|_{1,J_h,1},$ and this upper bound tends to zero. Hence,

$$
\int_{\Omega} \psi \partial_j u_j = 0.
$$

By density of $C_c^\infty(\Omega)^d \times C_c^\infty(\Omega)/\mathbb{R}$ in $H^1_0(\Omega)^d \times L^2_0(\Omega)$, this shows that $(u, p)$ solves the Stokes equations (37). Since the solution to this problem is unique, the whole sequence $\{\{u_h, p_h\}\}_{h \in \mathcal{H}}$ converges.

(iii) Strong convergence of the velocity gradient and convergence of velocity and pressure jumps. Observe that

$$
\int_{\Omega} f_i u_{h,i} = l_h((u_h, p_h), (u_h, p_h)) \geq \nu a_h(u_{h,i}, u_{h,i}) + s_h(p_h, p_h)
$$

$$
\geq \nu a_h(u_{h,i}, u_{h,i}) \geq \sum_{i=1}^d \nu \|G_h(u_{h,i})\|_{L^2(\Omega)^d}^2.
$$

Thus,

$$
\limsup\sum_{i=1}^d \nu \|G_h(u_{h,i})\|_{L^2(\Omega)^d}^2 \leq \limsup\int_{\Omega} f_i u_{h,i} = \int_{\Omega} f_i u_i = \nu \|\nabla u\|_{L^2(\Omega)^d}^2.
$$

Proceeding as for the Poisson problem, it is inferred that $G_h(u_{h,i}) \rightarrow \nabla u_i$ for all $i \in \{1, \ldots, d\}$ in $L^2(\Omega)^d$ and that $|u_{h,i}|_{1,F_{h,i}} \rightarrow 0$. Finally, since

$$
|p_h|_{1,F_{h,i}}^2 = b_h(u_h, p_h) = \int_{\Omega} f_i u_{h,i} - \nu a_h(u_{h,i}, u_{h,i}),
$$

it is inferred that $|p_h|_{1,F_{h,i}} \rightarrow 0$.

(iv) Strong convergence of the pressure. Using again the result by Nečas [32], let $v(p_h) \in H^1_0(\Omega)^d$ be s.t. $\nabla \cdot v(p_h) = p_h$ with $\|v(p_h)\|_{H^1(\Omega)^d} \leq c_0 \|p_h\|_{L^2(\Omega)}$ and set $v_h = \pi_h^k v(p_h)$. Then, proceeding as in the proof of Lemma [4.4], yields

$$
\|p_h\|_{L^2(\Omega)} \leq c_0 \|\pi_h^k p_h\|_{1,F_{h,i}} \|p_h\|_{L^2(\Omega)} - b_h(v_h, p_h)
$$

$$
\leq c_0 \|\pi_h^k p_h\|_{1,F_{h,i}} \|p_h\|_{L^2(\Omega)} + \nu a_h(u_{h,i}, v_{h,i}) - \int_{\Omega} f_i v_{h,i} = T_1 + T_2 - T_3.
$$

Since $|p_h|_{1,F_{h,i}}$ tends to zero and $\|p_h\|_{L^2(\Omega)}$ is bounded, $T_1$ converges to zero. Furthermore, since the sequence $\{v_h\}_{h \in \mathcal{H}}$ is bounded in the $\|\cdot\|_{DG}$-norm because
\[ \|v_h\|_{DG} \leq c_k,\nu \|v(h)\|_{H^1(\Omega)^d} \leq c_{\Omega,k,\nu} \|p_h\|_{L^2(\Omega)}, \]

there is \( v \in H^1_0(\Omega)^d \) such that, up to a subsequence, \( v_h \to v \) strongly in \( L^2(\Omega)^d \) and \( G_h(v_{h,i}) \rightharpoonup \nabla v_i \) weakly in \( L^2(\Omega)^d \) for all \( i \in \{1, \ldots, d\} \). Owing to the uniqueness of the limit in the distribution sense, it is inferred that \( \nabla \cdot v = p \). Consider now the terms \( T_2 \) and \( T_3 \). It is clear that \( T_3 \to \int_\Omega f \cdot v \). Furthermore,

\[ T_2 = \nu a_h(u_{h,i}, v_{h,i}) = \nu \int_\Omega G_h(u_{h,i}) G_h(v_{h,i}) + \nu j_h(u_{h,i}, v_{h,i}) = T_{2,1} + T_{2,2}. \]

Owing to the strong convergence of \( \{G_h(u_{h,i})\}_{h \in \mathcal{H}} \) in \( L^2(\Omega)^d \) and to the weak convergence of \( \{G_h(v_{h,i})\}_{h \in \mathcal{H}} \) in \( L^2(\Omega)^d \), it is inferred that \( T_{2,1} \to \nu \int_\Omega \partial_i u_i \partial_j v_i \). Moreover,

\[ |T_{2,2}| \leq c_{\nu,k,\nu} |u_h|_{1,F_{\kappa},-1}^1 |v_h|_{1,F_{\kappa},-1} \leq C|u_h|_{1,F_{\kappa},-1}, \]

which converges to zero. Collecting the above estimates leads to

\[ \limsup \|p_h\|_{L^2(\Omega)} \leq \nu \int_\Omega \partial_i u_i \partial_j v_i - \int_\Omega f_i v_i = \int_\Omega p \partial_i v_i = \|p\|_{L^2(\Omega)}, \]

classically yielding the strong convergence of the pressure in \( L^2(\Omega) \).

**Remark 4.2.** If the exact solution \((u, p)\) turns out to be more regular and belongs to the broken Sobolev space \( H^{k+1}(T_h)^d \times H^k(T_h) \), optimal a priori error estimates of the form \( \|(u - u_h, p - p_h)\|_{S} \leq c_{u,p} \text{size}(T_h)^k \) can be established; see e.g. [11, 14, 19].

## 5. The Steady Incompressible Navier–Stokes Equations

In this section the space dimension is either 2 or 3. Let \( f \in L^r(\Omega)^d \) with \( r = \frac{6}{5} \) if \( d = 3 \) and \( r > 1 \) if \( d = 2 \). Let \( \nu > 0 \). Consider the steady incompressible Navier–Stokes equations in conservative form

\[ \begin{cases} -\nu \Delta u_i + \partial_j (u_i u_j) + \partial_i p = f_i, & \text{in } \Omega, \quad i \in \{1, \ldots, d\}, \\ \partial_i u_i = 0, & \text{in } \Omega, \\ u = 0, & \text{on } \partial \Omega, \\ \int_\Omega p = 0. \end{cases} \]

The weak formulation of this system consists in finding \((u, p) \in H_0^1(\Omega)^d \times L^2_0(\Omega)\) s.t. for all \((v, q) \in H_0^1(\Omega)^d \times L^2_0(\Omega)\)

\[ \nu \int_\Omega \partial_j u_i \partial_j v_i + \int_\Omega \partial_j (u_i u_j) v_i - \int_\Omega p \partial_j v_i + \int_\Omega q \partial_i u_i = \int_\Omega f_i v_i. \]

The existence of a weak solution in the above sense, in two and three space dimensions, is a classical result; see, e.g., [23, 26]. The uniqueness of the solution holds only under small data assumptions; see Remark 5.1 below.

### 5.1. Design of the Convective Trilinear Form

We choose the same discrete spaces for the velocity and for the pressure as for the Stokes equations. To allow for some generality in the treatment of the convective term, we introduce two parameters \( \alpha_1, \alpha_2 \in \{0, 1\} \) and rewrite the momentum equation in the Navier–Stokes equations as

\[ -\nu \Delta u_i + \partial_j (u_i u_j) - \alpha_1 \frac{1}{2} (\partial_j u_j) u_i + \alpha_2 \frac{1}{2} \partial_i (u_j u_j) + \partial_i \bar{p} = f_i, \]

with the modified pressure

\[ \bar{p} \overset{\text{def}}{=} p - \alpha_2 \frac{1}{2} (u_j u_j). \]
The choice \((\alpha_1, \alpha_2) = (1, 0)\) corresponds to Temam’s device (see e.g. [33]) to achieve stability. The choice \((\alpha_1, \alpha_2) = (0, 1)\) has been hinted at in [10]: the modified pressure \(\overline{\rho}\) differs from the Bernoulli pressure but the advantage is that the left-hand side of (58) is in divergence form, thereby lending itself to a conservative discretization. Define on \([H^1_0(\Omega)]^3\) the trilinear form

\[
(60) \quad t(w, u, v) \overset{\text{def}}{=} \int_\Omega \partial_j(w_i u_j) v_i - \alpha_1 \frac{1}{2} \int_\Omega (\partial_j w_j) u_i v_i + \alpha_2 \frac{1}{2} \int_\Omega \partial_i(w_j u_j) v_i.
\]

The discrete counterpart of the trilinear form \(t\) is a trilinear form \(t_h\) defined on \([U_h]^3\) and for which the following design conditions are relevant.

\((\text{T1})\) For all \(v_h \in U_h\),

\[
t_h(v_h, v_h, v_h) = 0.
\]

\((\text{T2})\) There is \(c_t\), depending on \(k\) and \(P\), such that for all \((w_h, u_h, v_h) \in [U_h]^3\),

\[
t_h(w_h, u_h, v_h) \leq c_t \|w_h\|_{DG} \|u_h\|_{DG} \|v_h\|_{DG}.
\]

\((\text{T3})\) Let \(\{u_h\}_{h \in H}\) be a sequence in \(U_h\), bounded in the \(\|\cdot\|_{DG}\)-norm. Then, for all \(\varphi \in C_\infty(\Omega)^d\), as size \((T_h) \to 0\), up to a subsequence,

\[
t_h(u_h, u_h, \pi_h \varphi) \to t(u, u, \varphi),
\]

where \(u \in H^1_0(\Omega)^d\) is given by Theorem 2.2.

\((\text{T4})\) Assume furthermore that, for all \(i \in \{1, \ldots, d\}\), \(G_h(u_h, i) \to \nabla u_i\) strongly in \(L^2(\Omega)^d\) and that \(\|u_h\|_{\mathcal{H}, \mathcal{H}, -1} \to 0\). Let \(\{v_h\}_{h \in H}\) be another sequence in \(U_h\), bounded in the \(\|\cdot\|_{DG}\)-norm. Then, as size \((T_h) \to 0\), up to a subsequence,

\[
t_h(u_h, v_h, v_h) \to t(u, u, v),
\]

where \(v \in H^1_0(\Omega)^d\) is given by Theorem 2.2.

5.2. **Discrete well-posedness and basic stability estimates.** The discrete problem consists in finding \((u_h, p_h) \in X_h\) s.t.

\[
(61) \quad l_h((u_h, p_h), (v_h, q_h)) + t_h(u_h, u_h, v_h) = \int_\Omega f_i v_{h,i}, \quad \forall (v_h, q_h) \in X_h,
\]

where the bilinear form \(l_h\) associated with the Stokes equations is defined by (60).

In this section, the discrete trilinear form \(t_h\) is assumed to satisfy (T1)–(T2) only.

**Lemma 5.1** (A priori estimates). Let \((u_h, p_h) \in X_h\) and assume that \((u_h, p_h)\) solves (61). Then, the following a priori estimates hold:

\[
(62) \quad (\nu \alpha)^2 \|u_h\|^2_{DG} + 2\alpha \nu |p_h|^2_{\mathcal{H}, \mathcal{H}, 1} \leq \frac{\alpha^2}{2} \|f\|_{L^r(\Omega)}^2,
\]

\[
(63) \quad c_t \|f\| \leq \sigma_{r'} \|f\|_{L^r(\Omega)} + c_t (\nu \alpha)^{-2} (\sigma_{r'} \|f\|_{L^r(\Omega)})^2.
\]

**Proof.** To prove (62), simply test (61) with \((u_h, p_h)\), observe that \(t_h(u_h, u_h, u_h) = 0\) owing to (T1) and use Lemma 4.2 for the linear part yielding

\[
\nu \alpha \|u_h\|^2_{DG} + |p_h|^2_{\mathcal{H}, \mathcal{H}, 1} \leq \int_\Omega f_i u_{h,i} \leq \sigma_{r'} \|f\|_{L^r(\Omega)} \|u_h\|_{DG},
\]

whence (62) is easily deduced. To prove (63), use the inf-sup condition in Lemma 4.3 and assumption (T2) to infer

\[
c_t \|f\| \leq \sigma_{r'} \|f\|_{L^r(\Omega)} + c_t \|u_h\|^2_{DG},
\]

and conclude using (62). \(\square\)
To prove the existence of a discrete solution, we use a topological degree argument; see, e.g., [20, 24] for the use of this argument in the convergence analysis of FV schemes and [13] for a general presentation.

**Lemma 5.2.** Let $V$ be a finite dimensional functional space equipped with a norm $\| \cdot \|_V$, let $\mu > 0$, and let $\Psi : V \times [0, 1] \to V$ satisfying the following assumptions:

(i) $\Psi$ is continuous.

(ii) $\Psi(\cdot, 0)$ is an affine function and the equation $\Psi(v, 0) = 0$ has a solution $v \in V$ such that $\|v\|_V < \mu$.

(iii) For any $(v, \rho) \in V \times [0, 1]$, $\Psi(v, \rho) = 0$ implies $\|v\|_V \neq \mu$.

Then, there exists $v \in V$ such that $\Psi(v, 1) = 0$ and $\|v\|_V < \mu$.

**Proposition 5.1.** For all $h \in \mathcal{H}$, the discrete problem (61) admits at least one solution $(u_h, p_h) \in X_h$.

**Proof.** To apply Lemma 5.2 let $V = X_h$ and define the mapping $\Psi : X_h \times [0, 1] \to X_h$ such that for $(u_h, p_h)$ given in $X_h$ and $\rho$ given in $[0, 1]$, $(\xi_h, \zeta_h) \overset{\text{def}}{=} \Psi((u_h, p_h), \rho) \in X_h$ is defined such that for all $(v_h, q_h) \in X_h$,

$$
(\xi_h, v_h)_{L^2(\Omega)} = h((u_h, p_h), (v_h, 0)) + \rho t_h(u_h, u_h, v_h) - \int_{\Omega} f_i v_{h,i},
$$

$$
(\zeta_h, q_h)_{L^2(\Omega)} = h((u_h, p_h), (0, q_h)).
$$

Observing that $l_h$ is continuous on $X_h \times X_h$ for the $\| \cdot \|_S$-norm, using (T2) and the equivalence of norms in finite dimension, it is inferred that $\Psi$ is continuous. Furthermore, point (iii) in Lemma 5.2 results from the a priori estimate for the Stokes equations. In addition, because of (T1), if $(u_h, p_h) \in X_h$ is such that $\Psi((u_h, p_h), \rho) = 0$ for some $\rho \in [0, 1]$, then $(u_h, p_h)$ is bounded independently of $\rho$. This concludes the proof. \( \square \)

### 5.3. Convergence analysis

In this section, we are now interested in the convergence of a sequence $\{(u_h, p_h)\}_{h \in \mathcal{H}}$ of solutions to the discrete problem (61) towards a solution $(u, p)$ of the Navier–Stokes equations (67). The same convergence result can be established as for the Stokes equations. The only difference is that, because we do not make a smallness assumption on the data, there is no uniqueness result available at the continuous level, and thus only the convergence of subsequences (and not of the whole sequence) is obtained.

**Theorem 5.1** (Convergence for Navier–Stokes equations). Let $\{(u_h, p_h)\}_{h \in \mathcal{H}}$ be a sequence of approximate solutions generated by solving the discrete problems (61) on the admissible meshes $\{T_h\}_{h \in \mathcal{H}}$. Assume (T1)–(T3). Then, as $\text{size}(T_h) \to 0$, up to a subsequence,

\begin{align*}
(64) & \quad u_h \to u, \quad \text{in } L^2(\Omega)^d, \\
(65) & \quad \nabla_h u_h \to \nabla u, \quad \text{in } L^2(\Omega)^{d,d}, \\
(66) & \quad |u_h|_{1, \mathcal{F}_h, -1} \to 0, \\
(67) & \quad p_h \rightharpoonup \bar{p}, \quad \text{weakly in } L^2(\Omega), \\
(68) & \quad |p_h|_{1, \mathcal{F}_h, 1} \to 0,
\end{align*}

where $(u, \bar{p} + \alpha_2 \frac{1}{2} (u, u)) \in H_0^1(\Omega) \times L^2(\Omega)$ is a solution to (67). Moreover, if (T4) also holds, then $p_h \to \bar{p}$ in $L^2(\Omega)$.
Proof. (i) Proceeding as for the Stokes equations, it is clear that there is \((u, \overline{p}) \in H_0^1(\Omega) \times L_2^0(\Omega)\) s.t., up to a subsequence, \(u_h \to u\) strongly in \(L^2(\Omega)^d\), \(G_h(u_{h,i}) \to \nabla u_i\) weakly in \(L^2(\Omega)^d\) for all \(i \in \{1, \ldots, d\}\) and \(p_h \to \overline{p}\) weakly in \(L^2(\Omega)\).

(ii) Identification of the limit. Using (T3) and proceeding as for the Stokes equations to treat the linear part, it is inferred that for all \(\varphi \in C_c^\infty(\Omega)^d\),
\[
\nu \int _\Omega \partial_j u_i \partial_j \varphi_i + t(u, u, \varphi) - \int _\Omega \overline{p} \partial_j \varphi_j = \int _\Omega f_i \varphi_i,
\]
and that for all \(\psi \in C_c^\infty(\Omega)/\mathbb{R}\),
\[
\int _\Omega \psi \partial_j u_j = 0.
\]
Hence, \((u, \overline{p} + \alpha_2 \frac{1}{2}(u_i u_j))\) solves the incompressible Navier–Stokes equations.

(iii) Strong convergence of the velocity, the pressure, and their jumps. Proceeding as for the Stokes equations, (T1) yields the strong convergence of the broken velocity gradient in \(L^2(\Omega)^d\) and the convergence to zero of the jump seminorms \(|u_{h,i}|_{1,h,-1}\) and \(|p_{h,i}|_{1,h,1}\). Furthermore, using again the velocity lifting of \(p_h\) yields
\[
\|p_h\|_{L^2(\Omega)}^2 \leq c_{\Omega,k,p} \|p_h\|_{L^2(\Omega)} \|u_h\|_{L^2(\Omega)}^2 + \nu \alpha_1 (u_{h,i}, v_{h,i}) + t_h(u_h, u_h, v_h) - \int _\Omega f_i v_{h,i} = T_1 + T_2 + T_4.
\]
The convergence of \(T_1, T_2, \) and \(T_4\) is treated the same as for the Stokes equations, while the convergence of \(T_3\) results from assumption (T4). As a result,
\[
\limsup \|p_h\|_{L^2(\Omega)}^2 \leq \nu \int _\Omega \partial_j u_i \partial_j v_i + t(u, u, v) - \int _\Omega f_i v_i = \int _\Omega p(\partial_i v_i) + \alpha_2 \frac{1}{2} \int _\Omega \partial_i (u_j u_j) v_i = \int _\Omega \overline{p}(\partial_i v_i) = \|\overline{p}\|_{L^2(\Omega)}^2,
\]
concluding the proof.

\[\square\]

Remark 5.1. Under a smallness condition of the form
\[c_{\Omega,k,p}\nu^{-2}\|f\|_{L^2(\Omega)^d} < 1,\]
uniqueness of the weak solution of (T1) classically holds, so that the conclusions (64)–(68) of Theorem 5.1 apply to the whole sequence \(\{(u_h, p_h)\}_{h \in \mathcal{H}}\). Moreover, the convergence of the fixed-point iterative scheme
\[
l_h((u_h^{k+1}, p_h^{k+1}), (v_h, q_h)) + t_h(u_h^k, u_h^k, v_h) = \int _\Omega f_i v_{h,i}, \quad \forall (v_h, q_h) \in X_h,
\]
can be proven using standard arguments.

5.4. Examples. Define for \((w_h, u_h, v_h) \in [U_h]^3\),
\[
t_h(w_h, u_h, v_h) = \int _\Omega (w_h \nabla_h u_h) \cdot v_h - \sum _{F \in \mathcal{F}_h} \int _F \left\| w_h \right\|_{\mathcal{F}} \left\| u_h \right\|_{\mathcal{F}} \left\| v_h \right\|
\]
\[
+ \int _\Omega \frac{1}{2} (\nabla_h w_h)(u_h, v_h) - \sum _{F \in \mathcal{F}_h} \int _F \left\| w_h \right\|_{\mathcal{F}} \frac{1}{2} \left\| u_h \right\|_{\mathcal{F}} \left\| v_h \right\|.
\]
This choice corresponds to \((\alpha_1, \alpha_2) = (1, 0)\). The resulting DG method is not conservative, since it contains a source term proportional to the divergence of the discrete velocity (still converging to zero as the mesh is refined).
Proposition 5.2. Let $t_h$ be defined by (69). Then, assumptions (T1)–(T4) hold.

Proof. The verification of (T1) is straightforward. Assumption (T2) results from the Sobolev embedding with $q=4$ and trace inequalities. To prove (T3) and (T4), observe first that for all $v_h \in U_h$,

$$t_h(u_h, u_h, v_h) = \int_\Omega u_h \mathcal{G}^{2k}_h (u_h, i) v_h + \frac{1}{4} \sum_{F \in \mathcal{F}_h} \int_F \|u_h\| \|v_h\| \|v_h, i\|$$

$$+ \int_\Omega \frac{1}{2} u_h, i v_h, i = T_1 + T_2 + T_3.$$

To prove (T3), take $v_h = \pi_h \varphi$ with $\varphi \in C^\infty_c(\Omega)^d$. Owing to the discrete Sobolev embedding with $q=4$, the sequences $\{\pi_h \varphi\}_{h \in \mathcal{H}}$ are bounded in $L^4(\Omega)^d$. Hence, Lebesgue’s Dominated Convergence Theorem implies that, up to a subsequence, $u_h \pi_h \varphi$ converges to $u \varphi$ in $L^2(\Omega)^d$. In addition, $\{\mathcal{G}^{2k}_h (u_h, i)\}_{h \in \mathcal{H}}$ weakly converges to $\nabla u_i$ in $L^2(\Omega)^d$. As a result, $T_1$ converges to $\int_\Omega u_i (\partial_j u_i) \varphi_i$. Similarly, $T_3$ converges to $\int_\Omega \frac{1}{2} (\partial_j u_j) u_i \varphi_i$. Furthermore, $T_2 \to 0$ since $|u_h|_{1, \mathcal{F}_h, -1}$ is bounded and $\max_{F \in \mathcal{F}_h} \|v_h\| L^\infty(F) \to 0$. Therefore, as $\text{size}(T_h) \to 0$,

$$t_h(u_h, u_h, \pi_h \varphi) \to \int_\Omega u_i (\partial_j u_i) \varphi_i + \int_\Omega \frac{1}{2} (\partial_j u_j) u_i \varphi_i = \int_\Omega [\partial_j (u_i u_j) - \frac{1}{2}(\partial_i u_j) u_j] \varphi_i,$$

yielding the trilinear form $t$ with $(\alpha_1, \alpha_2) = (1, 0)$. Assumption (T4) is proven similarly for the terms $T_1$ and $T_3$. To prove that $T_2$ converges to zero, observe that $|u_h|_{1, \mathcal{F}_h, -1}$ converges to zero and that $\max_{F \in \mathcal{F}_h} \|v_h\| L^\infty(F) \to 0$.

Now define for $(w_h, u_h, v_h) \in [U_h]^3$,

$$t_h(w_h, u_h, v_h) = -\int_\Omega w_h, i u_h \nabla v_h, i + \sum_{F \in \mathcal{F}_h} \int_F \nu_F \|u_h\| \|w_h, i\| \|v_h, i\|$$

$$+ \int_\Omega \frac{1}{2} w_h, i \nabla (u_h, i) v_h, i - \sum_{F \in \mathcal{F}_h} \int_F \nu_F \|v_h\| \|w_h, i\| \|v_h, i\|.$$  

(70)

This choice corresponds to $(\alpha_1, \alpha_2) = (0, 1)$. The salient feature of the resulting DG method is that it is locally conservative.

Proposition 5.3. Let $t_h$ be defined by (70). Then, assumptions (T1)–(T4) hold.

Proof. Assumptions (T1)–(T2) can be readily verified. To prove (T3) and (T4), proceed as in the previous proof by observing that for all $v_h \in U_h$,

$$t_h(u_h, u_h, v_h) = -\int_\Omega u_h, i u_h \mathcal{G}^{2k}_h (v_h, i) - \frac{1}{4} \sum_{F \in \mathcal{F}_h} \int_F \nu_F \|u_h\| \|u_h, i\| \|v_h, i\|$$

$$- \int_\Omega \frac{1}{2} u_h, i u_h, i \mathcal{G}^{2k}_h (v_h).$$

In particular, for all $\varphi \in C^\infty_c(\Omega)^d$, as $\text{size}(T_h) \to 0$,

$$t_h(u_h, u_h, \pi_h \varphi) \to \int_\Omega [\partial_j (u_i u_j) + \frac{1}{2} \partial_i (u_j u_j)] \varphi_i,$$

yielding the trilinear form $t$ with $(\alpha_1, \alpha_2) = (0, 1)$. □
Table 1. Convergence results for the trilinear form defined by (69). We have set $e_h = (e_{h,u}, e_{h,p}) \overset{\text{def}}{=} (u - u_h, p - p_h)$.

Figure 2. Plot of Kovasznay’s solution for $k = 1$ and mesh 5.

**Remark 5.2.** Upwinding can be introduced in the discrete trilinear forms $t_h$ defined by (69) or (70) by adding a term of the form

$$
\sum_{F \in \mathcal{T}_h} \theta_F \int_F \|w_h\| \cdot \nu_F \|u_h\| \cdot \|v_h\|,
$$

and replacing the design assumption (T1) by the requirement that $t_h$ be nonnegative, which is sufficient to derive all the necessary a priori estimates and the convergence result of Theorem 5.1. Here, the parameter $\theta_F \in [0, 1]$ depends on the local Péclet number.

5.5. **Numerical experiment.** To verify the asymptotic convergence properties of the method defined by (69), we have considered the analytical solution proposed in [28] on the square domain $\Omega \overset{\text{def}}{=} (-0.5, 1.5) \times (0, 2)$,

$$
u_1 = 1 - e^{-\pi x_2} \cos(2\pi x_2), \quad u_2 = -\frac{1}{2} e^{\pi x_1} \sin(2\pi x_2), \quad p = -\frac{1}{2} e^{\pi x_1} \cos(2\pi x_2) - \tilde{p},
$$

where $\tilde{p} = \frac{1}{2} \int_\Omega -\frac{1}{2} e^{\pi x_1} \cos(2\pi x_2) \simeq -0.920735694$ ensures zero-mean for the pressure, $\nu = \frac{1}{\sqrt{2}}$, and $f = 0$. The example was run on a family of uniformly refined triangular meshes with mesh sizes ranging from 0.5 down to 0.03125, labeled with progressive numbers from 1 to 5 in Table 1. The nonlinear problem was solved by the exact Newton algorithm with tolerance set to $10^{-6}$; the linear systems
were solved using the direct solver available in PETSc. According to Table 1, the method converges with optimal order in the energy norm defined by (48).

6. Discrete functional analysis in DG spaces

Let $1 \leq p < +\infty$ and let $k \geq 1$ be an integer. Equip the DG finite element space $V_h^k$ defined by (1) with the norm

$$
\|v_h\|_{DG,p}^p \overset{\text{def}}{=} \sum_{T \in \mathcal{T}_h} \int_T |\nabla v_h|^p_{p} + \sum_{F \in \mathcal{F}_h} \frac{1}{h_F^{p-1}} \int_F \|v_h\|^p,
$$

where $|\cdot|_{P}$ denotes the $l^p$-norm in $\mathbb{R}^d$ so that $|\nabla v_h|_{p} = \sum_{i=1}^{d} |\partial_i v_h|^p$ (the Euclidian norm in $\mathbb{R}^d$ can also be used). Recall that $\Omega$ is an open bounded connected subset of $\mathbb{R}^d$ ($d > 1$) whose boundary is a finite union of parts of hyperplanes. In this section, the mesh family $\{\mathcal{T}_h\}_{h \in \mathcal{H}}$ used to build the DG spaces is assumed to satisfy only assumptions (i)–(iv) in Definition 2.1.

The material contained in this section, which is closely inspired from that derived in [22] for discrete spaces of piecewise constant functions, deals with the extension to DG spaces of two key results of functional analysis, namely Sobolev embeddings and compactness criteria in $L^p(\Omega)$. These results are presented here in a non-Hilbertian setting which is more general than that needed to analyze the Navier–Stokes equations. We have made this choice because the results below are of independent interest to analyze other nonlinear problems; see also [21]. We also observe that we deal here with functional analysis in DG spaces and not in broken Sobolev spaces.

**Lemma 6.1.** For all $1 \leq s < t < +\infty$, the following holds for all $v_h \in V_h^k$,

$$
\|v_h\|_{DG,s} \leq c_{d,\mathcal{G}_1,|\Omega|,s,t} \|v_h\|_{DG,t}.
$$

**Proof.** Observing that for all $x \in \mathbb{R}^d$, $|x|_{d'} \leq d^{\frac{1}{d'} - \frac{1}{d}} |x|_{d}$ and using Hölder’s inequality with $\pi = \frac{d}{t} > 1$ and $\pi' = \frac{t}{t-1}$ yields

$$
\|v_h\|_{DG,s} = \sum_{T \in \mathcal{T}_h} \int_T |\nabla v_h|^s_{t'} + \sum_{F \in \mathcal{F}_h} \frac{1}{h_F^{s-1}} \int_F \|v_h\|^s \\
\leq \sum_{T \in \mathcal{T}_h} \int_T d^{\frac{s}{t}} |\nabla v_h|^s_{t'} + \sum_{F \in \mathcal{F}_h} h_F^{\frac{s}{t-1}} h_F^{\frac{1}{t-1}} \|v_h\|^s \\
\leq \left( \sum_{T \in \mathcal{T}_h} \int_T 1^{\pi'} \right)^{\frac{1}{\pi'}} \left( \sum_{T \in \mathcal{T}_h} \int_T |\nabla v_h|^s_{t'} \right)^{\frac{1}{\pi'}} \\
+ \left( \sum_{F \in \mathcal{F}_h} h_F^{\frac{1}{t-1}} \int_F 1^{\pi'} \right)^{\frac{1}{\pi'}} \left( \sum_{F \in \mathcal{F}_h} h_F^{\frac{s}{t-1}} \int_F \|v_h\|^s \right)^{\frac{1}{\pi'}} \\
\leq \left( (d + \mathcal{G}_1)|\Omega| \right)^{\frac{1}{\pi'}} \|v_h\|_{DG,t},
$$

using (1), whence the conclusion follows. \qed

**Lemma 6.2.** For $v \in L^1(\mathbb{R}^d)$, define

$$
\|v\|_{BV} = \sum_{i=1}^{d} \sup \left\{ \int_{\mathbb{R}^d} u \partial_i \varphi ; \varphi \in C^\infty_{c}(\mathbb{R}^d), \|\varphi\|_{L^\infty(\mathbb{R}^d)} \leq 1 \right\},
$$

License or copyright restrictions may apply to redistribution; see http://www.ams.org/journal-terms-of-use
and set $BV = \{ v \in L^1(\mathbb{R}^d) : \| v \|_{BV} < +\infty \}$. Then, extending discrete functions in $V_h^k$ by zero outside $\Omega$, there holds $V_h^k \subset BV$ and for all $1 \leq p < +\infty$,

(73) \[ \forall v_h \in V_h^k, \quad \| v_h \|_{BV} \leq c_{d,\partial_1,\Omega,p} \| v_h \|_{DG,p}. \]

Proof. Clearly, owing to Lemma 6.1, it suffices to prove (74) for $p = 1$. Integrating by parts, it is clear that for all $v_h \in V_h^k$ and for all $\varphi \in C^\infty_c(\mathbb{R}^d)$ with $\| \varphi \|_{L^\infty(\mathbb{R}^d)} \leq 1$,

\[ \int_{\mathbb{R}^d} v_h \partial_i \varphi = -\int_{\mathbb{R}^d} (e_i \nabla_h v_h) \varphi + \sum_{F \in T_h} \int_F e_i u_F [v_h] \varphi \leq \| v_h \|_{DG,1}. \]

Hence, $\| v_h \|_{BV} \leq d \| v_h \|_{DG,1}$, completing the proof. \hfill \Box

Remark 6.1. In this section we could have allowed the case $k = 0$, although the derived results are not as interesting as for $k \geq 1$ because $\| \cdot \|_{DG,0}$ is not the natural norm with which to equip the space $V_h^0$ when working with FV approximations to nonlinear second-order PDEs. Indeed, on $V_h^0$, the first term on the right-hand side of (71) (the broken gradient) drops out, and this entails that a length scale different from $h_F$ must be used for the jump term, thereby also requiring an additional (mild) assumption on the mesh family; see [22] for the analysis in this case.

Remark 6.2. The observation that the $\| \cdot \|_{DG,2}$-norm controls the BV-norm can also be found in [30] in the framework of linear elasticity.

6.1. Discrete Sobolev embeddings.

Theorem 6.1 (Discrete Sobolev embeddings). For all $q$ such that

(i) $1 \leq q \leq p^* \overset{\text{def}}{=} \frac{d}{d-p}$ if $1 \leq p < d$,
(ii) $1 \leq q < +\infty$ if $d \leq p < +\infty$,

there is $\sigma_{q,p}$ such that

(74) \[ \forall v_h \in V_h^k, \quad \| v_h \|_{L^q(\Omega)} \leq \sigma_{p,q} \| v_h \|_{DG,p}. \]

The constant $\sigma_{q,p}$ additionally depends on $k$, $|\Omega|$, and $\mathcal{P}$. In particular, for the choice $q = p$ which is always possible,

(75) \[ \forall v_h \in V_h^k, \quad \| v_h \|_{L^p(\Omega)} \leq \sigma_{p,p} \| v_h \|_{DG,p}. \]

Proof. We follow L. Nirenberg’s proof of Sobolev embeddings.

(i) The case $p = 1$. Set $1^* \overset{\text{def}}{=} \frac{d}{d-1}$. Then, owing to a classical result (see, e.g. [22] for a proof), for all $v \in BV$,

\[ \| v \|_{L^1(\mathbb{R}^d)} \leq \frac{1}{2d} \| v \|_{BV}. \]

Extending discrete functions in $V_h^k$ by zero outside $\Omega$, Lemma 6.2 yields

(76) \[ \| v_h \|_{L^1(\mathbb{R}^d)} \leq \frac{1}{2} \| v_h \|_{DG,1}, \]

i.e., (74) for $p = 1$ and $q = 1^*$ with $\sigma_{1,1^*} = \frac{1}{2}$, and hence for all $1 \leq q \leq 1^*$ since $\Omega$ is bounded.

(ii) The case $1 < p < d$. Set $\alpha = \frac{p(d-1)}{d-p}$ and observe that $\alpha > 1$. Considering the function $|v_h|^\alpha$ (extended by zero outside $\Omega$) and proceeding as above yields

(77) \[ 2 \left( \int_{\Omega} |v_h|^p \right)^\frac{d-1}{d} \leq \sum_{T \in T_h} \int_T |\nabla |v_h|^\alpha|_{T} + \sum_{F \in \mathcal{F}_h} \int_F \| |v_h|^\alpha \|_{F} \equiv T_1 + T_2. \]
Observe that a.e. in each $T \in \mathcal{T}_h$, $|\partial_i v_h|^\alpha = \alpha |v_h|^\alpha |\partial_i v_h|$ for all $i \in \{1, \ldots, d\}$ so that $|\nabla v_h|^\alpha \leq \alpha |v_h|^\alpha |\nabla v_h|$. Using Hölder’s inequality with $p$ and $q = \frac{p}{p-1}$, the first term in (77) is bounded as
\[
|T_1| \leq \alpha \left( \sum_{T \in \mathcal{T}_h} \int_T |v_h|^{\alpha(q-1)} \right)^{\frac{1}{q}} \left( \sum_{T \in \mathcal{T}_h} \int_T |\nabla v_h|^p_1 \right)^{\frac{1}{p}}.
\]
Furthermore, observing that $\|v_h\| \leq 2\alpha\|v_h|^{\alpha-1}\|v_h\|$ and using again Hölder’s inequality, it is inferred that the second term in (77) is bounded as
\[
|T_2| \leq \alpha \left( \sum_{T \in \mathcal{T}_h} \sum_{F \subset \partial T} h_F^{-\frac{1}{q}} |v_h|^{\alpha-1} h_F^{-\frac{1}{2}} \|v_h\| \right)
\leq \alpha \left( \sum_{T \in \mathcal{T}_h} \sum_{F \subset \partial T} h_F |v_h|^p_1 \right)^{\frac{1}{q}} \left( \sum_{T \in \mathcal{T}_h} \sum_{F \subset \partial T} \frac{1}{h_F} \int_T \|v_h\| \right)^{\frac{1}{p}}
\leq \alpha \|v_h\| d^{\frac{1}{q}} \left( \int_\Omega |v_h|^p \right)^{\frac{1}{q}} \left( \sum_{F \subset \partial T} \frac{1}{h_F} \int_T \|v_h\| \right)^{\frac{1}{p}},
\]
where for $s \in \mathbb{R}_+$, $\tau_{s,k}$ is the constant in the trace inequality
\[
\forall \zeta \in P_k(T), \quad \sum_{F \subset \partial T} h_F \int_F |\zeta| \leq \tau_{s,k} \int_T |\zeta|,
\]
valid uniformly for all $h \in \mathcal{H}$ and for all $T \in \mathcal{T}_h$. This leads to
\[
2 \left( \int_\Omega |v_h|^p \right)^{\frac{d-1}{d}} \leq \alpha (d + 2 \tau_{\alpha, q} \tau_{p, q}) \left( \int_\Omega |v_h|^p \right)^{\frac{1}{q}} \|v_h\|_{DG,p}
\leq \alpha (d^{\frac{1}{q}} + 2 \tau_{\alpha, q} \tau_{p, q}) \left( \int_\Omega |v_h|^p \right)^{\frac{1}{q}} \|v_h\|_{DG,p}.
\]
Observing that $\frac{d-1}{d} - \frac{1}{q} = \frac{1}{p^*}$ yields (77).

(iii) The case $d \leq p < +\infty$. Fix any $q_1$ such that $p < q_1 < +\infty$ and set $p_1 = \frac{dq_1}{d+q_1}$ so that $1 < p_1 < d$ and $p_1^* = q_1$. Then, owing to point (ii) in this proof, it is inferred that for all $v_h \in V^k_h$, $\|v_h\|_{L^{q_1}(\Omega)} \leq \sigma_{p_1,q_1} \|v_h\|_{DG,p_1}$, and the conclusion follows from Lemma [6.1] since $p_1 \leq p$.

Remark 6.3. A trace inequality is used in the above proof when bounding $T_2$. This is why Theorem [6.1] is stated on DG spaces and not on broken Sobolev spaces. We restate that broken Sobolev spaces are not used in the present analysis.

6.2. Compactness. In this section we are interested in sequences $\{v_h\}_{h \in \mathcal{H}}$ in $V^k_h$ which are bounded in the $\|\cdot\|_{DG}$-norm.

**Theorem 6.2** (Compactness). Let $\{v_h\}_{h \in \mathcal{H}}$ be a sequence in $V^k_h$ and assume that this sequence is bounded in the $\|\cdot\|_{DG,p}$-norm. Then, the family $\{v_h\}_{h \in \mathcal{H}}$ is relatively compact in $L^p(\Omega)$ (and also in $L^p(\mathbb{R}^d)$ taking $v_h = 0$ outside $\Omega$).
Proof. Extending the functions $v_h$ by zero outside $\Omega$ and observing that (see, e.g. [22]) for all $\xi \in \mathbb{R}^d$,

$$\|v_h(\cdot + \xi) - v_h\|_{L^1(\mathbb{R}^d)} \leq |\xi|_{\ell^1} \|v_h\|_{BV} \leq C|\xi|_{\ell^1},$$

because of the boundedness of the sequence $\{v_h\}_{h \in \mathcal{H}}$ in the $\|\cdot\|_{DG,p}$-norm (and hence in the BV-norm owing to Lemma 6.2), Kolmogorov’s Compactness Criterion yields that the family $\{v_h\}_{h \in \mathcal{H}}$ is relatively compact in $L^1(\mathbb{R}^d)$. Owing to the Sobolev embedding (75), this sequence is also bounded in $L^p(\mathbb{R}^d)$; hence, it is also relatively compact in $L^p(\mathbb{R}^d)$. Finally, the relative compactness also holds in $L^p(\Omega)$ since the functions $v_h$ have been extended by zero outside $\Omega$.

**Theorem 6.3 (Regularity of the limit).** Let $1 < p < +\infty$. Let $\{v_h\}_{h \in \mathcal{H}}$ be a sequence in $V_h^k$ and assume that this sequence is bounded in the $\|\cdot\|_{DG,p}$-norm. Assume that size($T_h$) $\to 0$. Then, there exists $v \in W^{1,p}_0(\Omega)$ such that, up to a subsequence, $v_h \to v$ in $L^p(\Omega)$.

Proof. Owing to Theorem 6.2 there is $v \in L^p(\Omega)$ such that, up to a subsequence, $\{v_h\}_{h \in \mathcal{H}}$ converges to $v$ in $L^p(\Omega)$. It remains to prove that $v \in W^{1,p}_0(\Omega)$. To this purpose, we again extend the functions $v_h$ by zero outside $\Omega$ and we construct a discrete gradient converging, at least in the distribution sense over $\mathbb{R}^d$, to $\nabla v$.

1. Consider the lifting operators $r_F^0$ and $R_F^0$ defined in (24) and recall that the support of $r_F^0$ consists of the one or two mesh elements of which $F$ is a face. Hence,

$$\|R_F^0(\|v_h\|)\|_{L_p(\Omega)^d} = \sum_{T \subseteq T_h} \int_T \left| \sum_{F \subseteq \partial T} r_F^0(\|v_h\|) \right|_{\ell^p}$$

$$\leq \sum_{T \subseteq T_h} \int_T \sum_{F \subseteq \partial T} |r_F^0(\|v_h\|)_{\ell^p}$$

$$= N^{p-1}_0 \sum_{F \subseteq \partial T} \|r_F^0(\|v_h\|)\|_{L_p(\Omega)^d}.$$ 

Furthermore, setting for all $i \in \{1, \ldots, d\}$, $y_{h,i} = |r^0_{F,i}(\|v_h\|)|^{1-p} r^0_{F,i}(\|v_h\|)$, observing that $y_h \in [V_h^0]^d$ and using Hölder’s inequality with $p$ and $q = \frac{p}{p-1}$ yields

$$\|r^0_F(\|v_h\|)\|_{L_p(\Omega)^d} = \int_{\Omega} y_h \cdot r^0_F(\|v_h\|) = \int_{\Omega} \|v_h\| \cdot u_F(\|v_h\|)$$

$$\leq 2^{-\frac{1}{q}} \left( \sum_{T : F \subseteq \partial T} h_F \int_T |y_h|_{\ell^q} \right)^{\frac{1}{p}} \left( \frac{1}{h_F^{p-1}} \int_T \|v_h\|^{p} \right)^{\frac{1}{p}}$$

$$\leq 2^{-\frac{1}{q}} \left( \sum_{T : F \subseteq \partial T} h_F d_F^{\frac{1}{q}} \int_T |y_h|_{\ell^q} \right)^{\frac{1}{p}} \left( \frac{1}{h_F^{p-1}} \int_T \|v_h\|^{p} \right)^{\frac{1}{p}}$$

$$\leq c_{d,p,k} \|r^0_F(\|v_h\|)\|_{L_p(\Omega)^d} \left( \frac{1}{h_F^{p-1}} \int_F \|v_h\|^{p} \right)^{\frac{1}{p}}.$$ 

Collecting the above bounds yields

$$\|R_F^0(\|v_h\|)\|_{L_p(\Omega)^d} \leq c_{d,p,k} \left( \sum_{F \subseteq \partial T} \frac{1}{h_F^{p-1}} \int_F \|v_h\|^{p} \right)^{\frac{1}{p}}.$$
Then, upon defining the approximate gradient $G_h^0(v_h) = \nabla_h v_h - R_h^0([v_h]) \in [V_h^{k-1}]^d$ and extending it by zero outside $\Omega$, it is inferred that $\|G_h^0(v_h)\|_{L_p(\mathbb{R}^d)^d} \leq c_{d,p,k,p} \|v_h\|_{DG,p}$. Hence, the sequence $\{G_h^0(v_h)\}_{h \in H}$ is bounded in $L_p(\mathbb{R}^d)^d$, and thus since $p > 1$, up to a subsequence, $G_h^0(v_h) \rightharpoonup w$ weakly in $L_p(\mathbb{R}^d)^d$.

(ii) Let $\varphi \in C_c^\infty(\mathbb{R}^d)^d$ and observe that
\[
\int_{\mathbb{R}^d} G_h^0(v_h) \cdot \varphi = -\int_{\mathbb{R}^d} v_h (\nabla \cdot \varphi) - \int_{\mathbb{R}^d} R_h^0([v_h]) \cdot (\varphi - \pi_h^0 \varphi)
+ \sum_{F \in \mathcal{F}_h} \int_F \{\varphi - \pi_h^0 \varphi\} \cdot \nu_F [v_h] = T_1 + T_2 + T_3.
\]

Letting $\text{size}(T_h) \to 0$, we observe that $T_1 \to -\int_{\mathbb{R}^d} v (\nabla \cdot \varphi)$ and that $T_2 \to 0$ since $\|\varphi - \pi_h^0 \varphi\|_{L^q(\mathbb{R}^d)^d} \to 0$, $q = \frac{p}{p-1}$, and $\|R_h^0([v_h])\|_{L_p(\mathbb{R}^d)^d}$ is bounded. Furthermore, proceeding as usual,
\[
T_3 \leq C \|\varphi - \pi_h^0 \varphi\|_{L^\infty(\mathbb{R}^d)^d} (\Omega)^{\frac{1}{p}} \left( \sum_{F \in \mathcal{F}_h} \frac{1}{h_F^{p-1}} \int_F \|v_h\|^p \right)^{\frac{1}{p}} \leq C \|\varphi - \pi_h^0 \varphi\|_{L^\infty(\mathbb{R}^d)^d}
\]
whence it is inferred that $T_3 \to 0$. As a result,
\[
\int_{\mathbb{R}^d} w \cdot \varphi = \lim_{\text{size}(T_h) \to 0} \int_{\mathbb{R}^d} G_h^0(v_h) \cdot \varphi = -\int_{\mathbb{R}^d} v (\nabla \cdot \varphi).
\]
Hence, $w = \nabla v$ so that $v \in W^{1,p}(\Omega)$, and since $v$ is zero outside $\Omega$, $v \in W_0^{1,p}(\Omega)$. \hfill \Box

Remark 6.4. For $p = 2$, lifting operators using a higher polynomial degree $l \geq 1$ can also be considered as in the proof of Theorem 2.2. The difficulty for $p \neq 2$ is that the vector $y_h$ in the above proof is not necessarily polynomial-valued.

Acknowledgment

The authors are thankful to R. Eymard (University Paris-Est) for fruitful discussions.
