A SEMILOCAL CONVERGENCE ANALYSIS FOR DIRECTIONAL NEWTON METHODS

IOANNIS K. ARGYROS

ABSTRACT. A semilocal convergence analysis for directional Newton methods in \( n \)-variables is provided in this study. Using weaker hypotheses than in the elegant related work by Y. Levin and A. Ben-Israel and introducing the center-Lipschitz condition we provide under the same computational cost as in Levin and Ben-Israel a semilocal convergence analysis with the following advantages: weaker convergence conditions; larger convergence domain; finer error estimates on the distances involved, and an at least as precise information on the location of the zero of the function. A numerical example where our results apply to solve an equation but not the ones in Levin and Ben-Israel is also provided in this study.

1. INTRODUCTION

In this study we are concerned with the problem of approximating a zero \( x^* \) of a differentiable function \( F \) defined on a convex subset \( D \) of \( \mathbb{R}^n \) (\( n \) a natural number) with values in \( \mathbb{R} \).

A large number of problems in applied mathematics and also in engineering are solved by finding the solutions of certain equations.

More specifically, when it comes to computer graphics, we often need to compute and display the intersection \( \mathcal{C} = \mathcal{A} \cap \mathcal{B} \) of two surfaces \( \mathcal{A} \) and \( \mathcal{B} \) in \( \mathbb{R}^3 \) (see [5], [6]).

If the two surfaces are explicitly given by

\[
\begin{align*}
\mathcal{A} &= \{(u, v, w)^T : w = F_1(u, v)\} \\
\mathcal{B} &= \{(u, v, w)^T : w = F_2(u, v)\},
\end{align*}
\]

then the solution \( x^* = (u^*, v^*, w^*)^T \in \mathcal{C} \) must satisfy the nonlinear equation

\[
F_1(u^*, v^*) = F_2(u^*, v^*)
\]

and

\[
w^* = F_1(u^*, v^*).
\]

Hence, we must solve a nonlinear equation in two variables \( x = (u, v)^T \) of the form

\[
F(x) = F_1(x) - F_2(x) = 0.
\]
The marching method can be used to compute the intersection $C$. In this method, we first need to compute a starting point $x_0 = (u_0, v_0, w_0)^T \in C$, and then compute the succeeding intersection points by successive updating.

In mathematical programming [9], for an equality-constraint optimization problem, e.g.,
\[
\min \psi(x) \\
\text{s.t.} \quad F(x) = 0,
\]
where $\psi, F : D \subseteq \mathbb{R}^n \rightarrow \mathbb{R}$ are nonlinear functions, we need a feasible point to start a numerical algorithm. That is, we must compute a solution of the equation $F(x) = 0$.

In the case of a system of nonlinear equations $G(x) = 0$, with $G : D \subseteq \mathbb{R}^n \rightarrow \mathbb{R}^n$, we may solve instead
\[
\|G(x)\|_2 = 0
\]
if the zero of function $G$ is isolated or locally isolated and if the rounding error is neglected [3], [7], [10], [11], [12].

We use the directional Newton method (DNM) [5] given by
\[
x_{k+1} = x_k - \frac{F(x_k)}{\nabla F(x_k) \cdot d_k} d_k \quad (k \geq 0)
\]
to generate a sequence $\{x_k\}$ converging to $x^*$. Let us explain how (DNM) is conceived. We start with an initial guess $x_0 \in U_0$, where $F$ is differentiable and a direction vector $d_0$.

Then, we restrict $F$ on the line $A = \{x_0 + \theta d_0, \theta \in \mathbb{R}\}$, where it is a function of one variable $f(\theta) = F(x_0 + \theta d_0)$.

Set $\theta_0 = 0$ to obtain the Newton iteration for $f$, that is, the next point:
\[
v_1 = -\frac{f(0)}{f'(0)}.
\]
The corresponding iteration for $F$ is
\[
x_1 = x_0 - \frac{F(x_0)}{\nabla F(x_0) \cdot d_0} d_0.
\]
Note that $f(0) = F(x_0)$ and $f'(0)$ is the directional derivative
\[
f'(0) = F'(x_0, d_0) = \nabla F(x_0) \cdot d_0.
\]

By repeating this process we arrive at (DNM).

A semilocal convergence analysis for the (DNM) was provided in the elegant work by Levin and Ben-Israel in [5].

The quadratic convergence of the method was established for directions $d_k$ sufficiently close to the gradients $\nabla F(x_k)$, and under standard Newton–Kantorovich-type hypotheses [1]–[3], [7], [11]–[13].

In this study, we are motivated by the paper [5] and optimization considerations. By introducing the center-Lipschitz condition and using it, in combination with the Lipschitz condition (along the lines of our works in [1]–[3]), we provide a semilocal convergence analysis with the following advantages over the work in [5]:

1. Weaker hypotheses;
2. Larger convergence domain for (DNM);
3. Finer error bounds on the distances $\|x_{k+1} - x_k\|, \|x_k - x^*\| (k \geq 0)$;
2. Semilocal convergence analysis

We need the following lemma on majorizing sequences for (DNM). The proof can be found in the appendix.

Lemma 2.1. Assume: there exist constants \( L_0 \geq 0, L \geq 0, \) with \( L_0 \leq L, \) and \( \eta \geq 0, \) such that:

\[
q_0 = L \eta \begin{cases} 
\leq \frac{1}{2}, & \text{if } L_0 \neq 0, \\
< \frac{1}{2}, & \text{if } L_0 = 0,
\end{cases}
\]

where

\[
L = \frac{1}{8} \left( L + 4 L_0 + \sqrt{L^2 + 8 L_0 L} \right).
\]

Then, the sequence \( \{t_k\} \ (k \geq 0) \) given by

\[
t_0 = 0, \quad t_1 = \eta, \quad t_{k+1} = t_k + \frac{L (t_k - t_{k-1})^2}{2 (1 - L_0 t_k)} \quad (k \geq 1)
\]

is well defined, nondecreasing, bounded above by \( t^{**}, \) and converges to its unique least upper bound \( t^* \in [0, t^{**}] \), where

\[
t^{**} = \frac{2 \eta}{2 - \delta},
\]

\[
1 \leq \delta = \frac{4 L}{L + \sqrt{L^2 + 8 L_0 L}} < 2 \quad \text{for } L_0 \neq 0.
\]

Moreover, the following estimates hold:

\[
L_0 t^* \leq 1,
\]

\[
0 \leq t_{k+1} - t_k \leq \frac{\delta}{2} (t_k - t_{k-1}) \leq \cdots \leq \left( \frac{\delta}{2} \right)^k \eta \quad (k \geq 1),
\]

\[
t_{k+1} - t_k \leq \left( \frac{\delta}{2} \right)^k (2 q_0)^{2k-1} \eta \quad (k \geq 0),
\]

\[
0 \leq t^* - t_k \leq \left( \frac{\delta}{2} \right)^k \frac{(2 q_0)^{2k-1} \eta}{1 - (2 q_0)^{2k}} \quad (2 q_0 < 1), \quad (k \geq 0).
\]

Here, \( \angle \) denotes the angle between two vectors \( u \) and \( v, \) given by

\[
\angle(u, v) = \arccos \frac{u \cdot v}{\|u\| \cdot \|v\|}, \quad u \neq 0, \quad v \neq 0.
\]

We provide the main semilocal convergence theorem for (DNM):
Theorem 2.2. Let $F : D \subseteq \mathbb{R}^n \rightarrow \mathbb{R}$ be a differentiable function. Assume:

(i) There exists a point $x_0 \in D$, such that:

$$F(x_0) \neq 0, \quad \nabla F(x_0) \neq 0.$$ 

Let $d_0 \in \mathbb{R}^n$ be such that $\|d_0\| = 1$, and set

$$h_0 = -\frac{F(x_0)}{\nabla F(x_0) \cdot d_0} d_0,$$

$$x_1 = x_0 + h_0.$$ 

(ii) For $F \in C^2[D]$, there exist constants $M_0$ and $M$ such that:

$$\|\nabla F(x) - \nabla F(x_0)\| \leq M_0 \|x - x_0\|, \quad x \in D,$$

$$\sup_{x \in D} \|F''(x)\| = M,$$

$$p_0 = |F(x_0)| \quad \frac{\|\nabla F(x_0) \cdot d_0\|^{-2}}{2} \leq \frac{1}{2},$$

and

$$U_0 = \{x \in \mathbb{R}^n : \|x - x_0\| \leq t^*\} \subseteq D,$$

where

$$\mathcal{M} = \frac{1}{8} \left( M + 4 M_0 + \sqrt{M^2 + 8 M_0 M} \right).$$

(iii) The sequence $\{x_k\}$ ($k \geq 0$) given by

$$x_{k+1} = x_k + h_k,$$

where

$$h_k = -\frac{F(x_k)}{\nabla F(x_k) \cdot d_k} d_k,$$

satisfies

$$\angle(d_k, \nabla F(x_k)) \leq \angle(d_0, \nabla F(x_0)), \quad k \geq 0,$$

where each $d_k \in \mathbb{R}^n$ is such that $\|d_k\| = 1$.

Then the sequence $\{x_k\}$ remains in $U_0$ for all $k \geq 0$ and converges to a zero $x^* \in U_0$ of function $F$.

Moreover, $\nabla F(x^*) \neq 0$ unless $\|x^* - x_0\| = t^*$.

Furthermore, the following estimates hold for all $k \geq 0$:

$$\| x_{k+1} - x_k \| \leq t_{k+1} - t_k \leq \left( \frac{\delta}{2} \right)^k (2 p_0)^{2^k - 1} \eta$$

and

$$\| x_k - x^* \| \leq t^* - t_k \leq \left( \frac{\delta}{2} \right)^k \frac{(2 p_0)^{2^k - 1} \eta}{1 - (2 p_0)^{2^k}} (2 p_0 < 1),$$

where the iteration $\{t_k\}$ is given by

$L_0 = |\nabla F(x_0)|^{-1} M_0, \quad L = |\nabla F(x_0) \cdot d_0|^{-1} M, \quad \eta = |\nabla F(x_0) \cdot d_0|^{-1} |F(x_0)|.$
Note that condition (2.17) is equivalent to

\[
\frac{|\nabla F(x_k) \cdot d_k|}{\| \nabla F(x_k) \|} \geq \frac{|\nabla F(x_0) \cdot d_0|}{\| \nabla F(x_0) \|}, \quad k \geq 0.
\]

Proof. We shall show the following using mathematical induction on \(k \geq 0\):

\[
\| x_{k+1} - x_k \| \leq t_{k+1} - t_k
\]

and

\[
\overline{U}(x_{k+1}, t^* - t_{k+1}) \subseteq \overline{U}(x_k, t^* - t_k).
\]

For every \(z \in \overline{U}(x_1, t^* - t_1)\),

\[
\| z - x_0 \| \leq \| z - x_1 \| + \| x_1 - x_0 \| \leq t^* - t_1 + t_1 - t_0 = t^* - t_0
\]

shows that \(z \in \overline{U}(x_0, t^* - t_0)\).

Since, also

\[
\| x_1 - x_0 \| = \| h_0 \| \leq \eta = t_1 - t_0,
\]

estimates (2.21) and (2.22) hold for \(k = 0\).

Assume that (2.21) and (2.22) hold for all \(i \leq k\). Then we have:

\[
\| x_{k+1} - x_k \| \leq \| x_{k+1} - x_k \| + \| x_k - x_{k-1} \| + \cdots + \| x_1 - x_0 \| \leq (t_{k+1} - t_k) + (t_k - t_{k-1}) + \cdots + (t_1 - t_0) = t_{k+1}
\]

and

\[
\| x_k + t (x_{k+1} - x_k) - x_0 \| \leq t_k + t (t_{k+1} - t_k) \leq t^*, \quad t \in [0, 1].
\]

Using condition (2.10) for \(x = x_k\), we get in turn:

\[
\| \nabla F(x_k) \| \geq \| \nabla F(x_0) \| - \| \nabla F(x_k) - \nabla F(x_0) \| \geq \| \nabla F(x_0) \| - M_0 \| x_k - x_0 \| \geq \| \nabla F(x_0) \| - M_0 (t_k - t_0) \geq \| \nabla F(x_0) \| - M_0 t_k > 0 \quad \text{(by (2.22) and Lemma 2.1)}.
\]

We have the identity

\[
\int_{x_{k-1}}^{x_k} (x - x) F''(x) \, dx = -(x_k - x_{k-1}) \nabla F(x_{k-1}) + F(x_k) - F(x_{k-1})
\]

\[
= -h_{k-1} \nabla F(x_{k-1}) + F(x_k) - F(x_{k-1})
\]

\[
= \frac{F(x_{k-1})}{(F(x_{k-1}) \cdot d_{k-1})} (d_{k-1} \cdot \nabla F(x_{k-1})) + F(x_k) - F(x_{k-1})
\]

\[
= F(x_k).
\]

We prefer the integration to be from 0 to 1. That is why we introduce a change of variable given by \(x = x_{k-1} + t \, h_{k-1}, \, t \in [0, 1]\). We can write

\[
x_k - x = x_k - x_{k-1} - t \, h_{k-1} = h_{k-1} - t \, h_{k-1} = (1 - t) \, h_{k-1}, \quad dx = h_{k-1} \, dt.
\]
Then (2.25) can be written as:

\[(2.26) \quad F(x_k) = \int_0^1 (1 - t) \ h_{k-1} F''(x_{k-1} + \theta \ h_{k-1}) \ h_{k-1} \ d\theta.\]

Using (2.11), (2.15)–(2.20), we get in turn:

\[
\|x_{k+1} - x_k\| = \|h_k\| = \frac{|F(x_k)|}{|\nabla F(x_k) \cdot d_k|}
\]

\[
\leq \frac{\int_0^1 (1 - t) \ h_{k-1} F''(x_0 + \theta \ h_{k-1}) \ h_{k-1} \ d\theta|}{|\nabla F(x_k) \cdot d_k|}
\]

\[
\leq \frac{M \ ||h_{k-1}||^2}{2 ||\nabla F(x_k) \cdot d_k||}
\]

\[
\leq \frac{M \ ||h_{k-1}||^2 ||\nabla F(x_0)||}{2 ||\nabla F(x_k)|| ||\nabla F(x_0) \cdot d_0||}
\]

\[
\leq \frac{M \ ||h_{k-1}||^2}{2 (||\nabla F(x_0)|| - M_0 t_k) ||\nabla F(x_0) \cdot d_0||}
\]

\[
\leq \frac{M \ ||h_{k-1}||^2}{2 (1 - ||\nabla F(x_0) \cdot d_0||^{-1} M_0 t_k) ||\nabla F(x_0) \cdot d_0||}
\]

\[
= \frac{M \ (t_k - t_{k-1})^2}{2 (1 - ||\nabla F(x_0) \cdot d_0||^{-1} M_0 t_k) ||\nabla F(x_0) \cdot d_0||}
\]

which shows (2.24) for all \(k \geq 0\).

Then, for every \(w \in U(x_{k+2}, t^* - t_{k+2})\), we obtain:

\[
\|w - x_{k+1}\| \leq \|w - x_{k+2}\| + \|x_{k+2} - x_{k+1}\|
\]

\[
\leq t^* - t_{k+2} + t_{k+2} - t_{k+1} = t^* - t_{k+1},
\]

showing (2.22) for all \(k \geq 0\).

Lemma 2.1 implies that \(\{t_n\}\) is a Cauchy sequence. It then follows from (2.21) and (2.22) that \(\{x_n\}\) is a Cauchy sequence too, and as such it converges to some \(x^* \in U_0\) (since \(U_0\) is a closed set).

The point \(x^*\) is a zero of \(F\), since

\[
0 \leq |F(x_k)| \leq \frac{1}{2} \ M(t_k - t_{k-1})^2 \rightarrow 0 \quad \text{as} \quad k \rightarrow \infty.
\]

Furthermore, we prove that \(\nabla F(x^*) \neq 0\), except if \(x^* - x_0 = t^*\).

Using (2.10) for \(x \in U_0\), (2.10), and the definition of the constant \(L_0\), we get

\[
\|\nabla F(x) - \nabla F(x_0)\| \leq M_0 \ |x - x_0|
\]

\[
\leq M \ t^* \leq |\nabla F(x_0) \cdot d_0| \leq \|\nabla F(x_0)\|.
\]

If \(\|x - x_0\| < t^*\), then by (2.10), we obtain:

\[
\|\nabla F(x) - \nabla F(x_0)\| \leq M_0 \ |x - x_0| < M_0 t^* \leq \|\nabla F(x_0)\|,
\]
or
\[
\| \nabla F(x_0) \| > \| \nabla F(x) - \nabla F(x_0) \|
\]
which shows $\nabla F(x) \neq 0$.

The left-hand side inequality in (2.20) follows from (2.19) by using standard
majorization techniques [3], [6], [8], [9].

That completes the proof of Theorem 2.2. \(\square\)

Note that $t^*$ in (2.13) can be replaced by $t^{**}$ given in closed form by (2.4).

It follows from the proof of Theorem 2.2, and Lemma 2.1, that

\[
(2.27) \quad \| h_{k+1} \| \leq \frac{\delta}{2} \| h_k \| \quad (k \geq 0)
\]

Therefore, if we define the nested balls

\[
S_k = \{ x \in \mathbb{R}^n : \| x - x_{k+1} \| \leq \| h_k \| \},
\]

the proof given in [5] applies for Theorem 2.2 by simply replacing $\frac{1}{2}$ by $\frac{\delta}{2}$.

However, we decided to provide a proof for Theorem 2.2 different than the cor-
responding one in [5].

**Definition 2.3.** Let $F : D \subseteq \mathbb{R}^n \rightarrow \mathbb{R}$ be a differentiable function, where $D$ is a
convex region. The function $\nabla F$ is said to be Lipschitz continuous if there exists a
constant $M \geq 0$ such that:

\[
(2.28) \quad \| \nabla F(x) - \nabla F(y) \| \leq M \| x - y \| \quad \text{for all } x, y \in D.
\]

Note that in view of (2.28), there exists a center-Lipschitz constant $M_0 \geq 0$ such that
(2.10) holds.

Clearly,

\[
(2.29) \quad M_0 \leq M
\]
holds in general, and $\frac{M}{M_0}$ can be arbitrarily large [1]–[3].

**Remark 2.4.** If $F$ is twice differentiable, the Lipschitz constant $M$ in (2.28) can
replace the corresponding constant in hypothesis (2.11). Note also that in view of
the proof of Theorem 2.2 the constant $L_0$ can be defined by the more precise:

\[
L_0 = \| \nabla F(x_0) \|^{-1} M_0.
\]

**Remark 2.5.** Our Theorem 2.2 improves Theorem 1 in [5] pages 252–253],

(1) Case $M = M_0$: Theorem 1 in [5] uses the stronger, and more difficult to verify
than (2.17) condition:

\[
(2.30) \quad \angle(d_{k+1}, \nabla F(x_{k+1}) \leq \angle(d_k, \nabla F(x_k)) \quad (k \geq 0),
\]
or equivalently

\[
(2.31) \quad \frac{\| \nabla F(x_{k+1}) \cdot d_{k+1} \|}{\| \nabla F(x_{k+1}) \|} \geq \frac{\| \nabla F(x_k) \cdot d_k \|}{\| \nabla F(x_k) \|} \quad (k \geq 0).
\]

(1) Case $M_0 < M$: Theorem 1 in [5] again uses (2.30) instead of the weaker condi-
tion (2.17).
Theorem 1 in [5] uses the condition
\[(2.32)\]
P = |F(x_0)| M |\nabla F(x_0) \cdot d_0|^{-2} \leq \frac{1}{2}
corresponding to our condition (2.12).

But, we have
\[(2.33)\]
\[\overline{M} < M.\]

That is,
\[(2.34)\]
P \leq \frac{1}{2} \implies P_0 \leq \frac{1}{2},

but not necessarily vice versa (unless M_0 = L).

Define the sequence \(\{s_k\}\) \((k \geq 0)\) by
\[(2.35)\]
s_0 = 0, \quad s_{k+1} = s_k + \|h_k\|.

It was shown in [5] (under (2.32)) that
\[(2.36)\]
\[\|h_{k+1}\| \leq \frac{1}{2} \|h_k\|,
\]
i.e.,
\[(2.37)\]
\[s_{k+2} - s_{k+1} \leq \frac{1}{2} (s_{k+1} - s_k).
\]

It turns out from the proof of our Theorem 2.2 that a finer sequence \(\{\bar{t}_k\}\) than \(\{s_k\}\) could have been used in [5], given by
\[(2.38)\]
\[\bar{t}_0 = 0, \quad \bar{t}_1 = \eta, \quad \bar{t}_{k+1} = \bar{t}_k + \frac{L (\bar{t}_k - \bar{t}_{k-1})^2}{2 (1 - L \bar{t}_k)} \quad (k \geq 1).
\]

Note that \(L_0 \leq L\), since \(M_0 \leq M\). We showed in [2, page 392]:
\[(2.39)\]
t_k \leq \bar{t}_k,

\[(2.40)\]
t_{k+1} - t_k \leq \bar{t}_{k+1} - \bar{t}_k,

and
\[(2.41)\]
t^* \leq \bar{t}^* = \lim_{k \to \infty} \bar{t}_k.

Moreover, strict inequality holds in (2.39) and (2.40) if \(M_0 < M\) (i.e., if \(L_0 < L\)).

Note that the convergence in Theorem 2.2 is quadratic, whereas it was only shown to be linear in the corresponding Theorem 1 in [5] (see also (2.8), (2.9), and (2.36)).

Finally, it follows from Lemma 2.1 and the proof of Theorem 2.2 that the sequence
\[(2.42)\]
\[\gamma_0 = 0, \quad \gamma_1 = \eta, \quad \gamma_{k+1} = \gamma_k + \frac{L_1 (\gamma_k - \gamma_{k-1})^2}{2 (1 - L \gamma_k)} \quad (k \geq 1)
\]
is a finer majorizing sequence for \(\{x_k\}\) than \(\{t_k\}\), where
\[(2.43)\]
L_1 = \begin{cases} L_0, & \text{if } k = 1, \\ L, & \text{if } k > 1. \end{cases}

We can also show the following convergence result for (DNM):
Theorem 2.6. Under the hypotheses of Theorem 2.2 for the operator $F \in C^1[\mathcal{D}]$, and (2.11) replaced by (2.28), further assume that there exist constants $M_0 > 0$, $\beta_0 > 0$, $\beta > 0$, such that:

\begin{align*}
(2.44) & \quad |\nabla F(x_0) \cdot d_0| \geq \frac{1}{\beta_0}, \\
(2.45) & \quad |\nabla F(x) \cdot d| \geq \frac{1}{\beta}, \quad \text{for all } x \in U \subset \mathcal{D}, \ d \in \mathbb{R}^n, \ |d| = 1,
\end{align*}
and

\begin{align*}
(2.46) & \quad \alpha = \frac{M_0 \beta_0}{2} \leq 1. \\
\text{Set} & \quad a = \frac{M_0 \beta_0}{M \beta}.
\end{align*}

Then, the following estimates hold:

\begin{align*}
(2.48) & \quad \|x_{k+1} - x_k\| \leq a^{2^{k-1}} \alpha^{2^{k-1}} t_1 \\
\text{and} & \quad \|x^* - x_k\| \leq \frac{a^{2^{k-1}} \alpha^{2^{k-1}} t_1}{1 - a^{2^{k-1}} \alpha^{2^{k-1}} t_1} \quad \text{for all } k \geq 1 \ (\alpha < 1).
\end{align*}

Proof. According to Theorem 2.2, $x_k \in U_0 \ (k \geq 0)$. Using (2.15), (2.16), (2.44), and (2.45), we get in turn:

\begin{align*}
\|x_{k+1} - x_k\| &= \frac{|F(x_k)|}{|\nabla F(x_k) \cdot d_k|} \\
&\leq \beta_1 |F(x_k)| \\
&= \beta_1 |F(x_k) - F(x_{k-1}) - \nabla F(x_{k-1}) (x_k - x_{k-1})|,
\end{align*}
where

\begin{align*}
(2.51) & \quad \beta_1 = \begin{cases} 
\beta_0, & \text{if } k = 1, \\
\beta, & \text{if } k > 1.
\end{cases}
\end{align*}

Multiplying both sides of

\begin{align*}
(2.52) & \quad x_k - x_{k-1} = -\frac{F(x_{k-1})}{\nabla F(x_{k-1}) \cdot d_{k-1}} d_{k-1}
\end{align*}
by $\nabla F(x_{k-1})$, we obtain

\begin{align*}
(2.53) & \quad \|x_2 - x_1\| \leq \frac{\beta_1 M_0}{2} \|x_2 - x_1\|^2 = \frac{\beta_1 M}{2} \|x_1 - x_0\|^2 = a^{2^1 \alpha^{2^1-1}} t_1, \\
& \quad \|x_3 - x_2\| \leq \frac{\beta_1 M}{2} \|x_3 - x_2\|^2 \leq \frac{\beta_1 M}{2} a \ t_1 \alpha^2 = a^{2^2 \alpha^{2^2-1}} t_1, \\
& \quad \|x_{k+1} - x_k\| \leq \frac{a^{2^{k-1}} \alpha^{2^{k-1}} t_1}{1 - a^{2^{k-1}} \alpha^{2^{k-1}} t_1} \quad \text{for } k = 1, 2.
\end{align*}

That is, we showed

\begin{align*}
(2.54) & \quad \|x_{k+1} - x_k\| \leq a^{2^{k-1}} \alpha^{2^{k-1}} t_1 \quad \text{for } k = 1, 2.
\end{align*}
Assume it is correct up to \( k - 1 \). Then, we have:

\[
\| x_{k+1} - x_k \| \leq \frac{\beta_1 M}{2} \| x_k - x_{k-1} \|^2 \leq \frac{\beta_1 M}{2} \left( a^{2k-2} \alpha^{2k+1-1} t_1 \right) = a^{2k-1} \alpha^{2k-1} t_1,
\]

which completes the induction for (2.54) and shows (2.48).

Let \( m > k \). Then using (2.48), we can obtain in turn for \( \alpha < 1 \):

\[
\begin{align*}
\| x_m - x_k \| &\leq \| x_m - x_{m-1} \| + \| x_{m-1} - x_{m-2} \| + \cdots + \| x_{k+1} - x_k \| \\
&\leq \left( a^{2m-2} \alpha^{2m-1-1} + a^{2m-3} \alpha^{2m-2-1} + \cdots + a^{2k-1} \alpha^{2k-1} \right) t_1 \\
&\leq a^{2k-1} \alpha^{2k-1} \left( 1 + a^{2k-1} \alpha^{2k} + a^{2k-1} \alpha^{2k} \right) t_1 \\
&\quad + \left( a^{2k-1} \alpha^{2k} \right)^{m-k-1} t_1 \\
&= a^{2k-1} \alpha^{2k-1} \frac{1 - \left( a^{2k-1} \alpha^{2k} \right)^{m-k}}{1 - a^{2k-1} \alpha^{2k}} \eta \\
&\leq a^{2k-1} \alpha^{2k-1} \frac{\eta}{1 - a^{2k-1} \alpha^{2k}}.
\end{align*}
\]

By letting \( m \to \infty \) in (2.55), we obtain (2.49).

That completes the proof of Theorem 2.6. \( \Box \)

**Remark 2.7.** If \( \beta_0 = \beta \) and \( M_0 = M \), then \( a = 1 \), and our Theorem 2.6 reduces to a weaker version of Theorem 2 in [5].

Note that even in this case it is weaker, since (2.20) is used instead of (2.31). Otherwise (i.e., if \( \beta_0 < \beta \), \( M_0 = M \), or if \( \beta_0 = \beta \), \( M_0 < M \), or if \( \beta_0 < \beta \), \( M_0 < M \)) the ratio of the quadratic convergence is improved since \( a \in (0, 1) \).

3. Special cases and applications

The gradient method is now stated as a special case of Theorem 2.2.

**Corollary 3.1.** Define direction \( d_k \) and step \( h_k \) for all \( k \geq 0 \) by:

\[
d_k = \frac{\nabla F(x_k)}{\| \nabla F(x_k) \|}
\]

and

\[
h_k = -\frac{F(x_k)}{\| \nabla F(x_k) \|^2} \nabla F(x_k).
\]

Let \( F, x_0, U_0, M, \beta_0, \beta, p_0 \) be as in Theorems 2.2 and 2.6. Then, the following gradient method:

\[
x_{k+1} = x_k - \frac{F(x_k)}{\| \nabla F(x_k) \|^2} \nabla F(x_k) \quad (k \geq 0)
\]

satisfies the conclusions of Theorems 2.2 and 2.6.
Following \[5\], as a second application, the direction \(d_k\) in each iteration is chosen as the unit vector along the maximal value \(\left| \frac{\partial F}{\partial x_k} \right|\). The proof of Theorems \[2.2\] and \[2.6\] applies here, by replacing each occurrence of \(|\nabla F(x_k) \cdot d_k|\) by \(\|\nabla F(x_k)\|_\infty\), and by using the \(\infty\)–norm instead of the Euclidean norm. The following is the analog of Theorem \[2.2\].

**Theorem 3.2.** Let \(F : D \subseteq \mathbb{R}^n \rightarrow \mathbb{R}\) be a differentiable function. If \(x_0 \in D\) is such that \(F(x_0) \neq 0\), \(\nabla F(x_0) \neq 0\), let \(m(0)\) be an index such that
\[
|F'(x_0)| = \left| \frac{\partial F}{\partial x_{m(0)}}(x_0) \right| = \max_{j=1,\ldots,n} \left| \frac{\partial F}{\partial x_j}(x_0) \right|.
\]
Define:
\[
h_0[k] = \begin{cases} 
-\frac{F(x_0)}{|F'(x_0)|} & \text{if } k = m(0), \\
0 & \text{if } k \neq m(0), \\
x_1 = x_0 + h_0 & \text{if } k \neq m(0), 
\end{cases}
\]
and
\[
U_0 = \{x : \| x - x_0 \|_\infty \leq t^* \}.
\]
Assume \(F \in C^2[D]\),
\[
\sup_{x \in D} \| F''(x) \|_\infty = M,
\]
\[
\| \nabla F(x) - \nabla F(x_0) \|_\infty \leq M_0 \| x - x_0 \|_\infty \quad \text{for all } x \in D,
\]
\[
\overline{p_0} = |F(x_0)| \frac{\| F'(x_0) \|_\infty}{M} \left| \frac{\partial F}{\partial x_{m(0)}}(x_0) \right|^{-2} \leq \frac{1}{2},
\]
and
\[
U_0 \subseteq D,
\]
where \(\overline{M}\) is given by \[2.14\].
Define sequences \(\{x_k\}, \{h_k\}\) as follows:

Let \(m(k)\) be an index of the maximal modulus of \(\frac{\partial F}{\partial x_{m(k)}}(x_k)\),
\[
|F'(x_k)| = \left| \frac{\partial F}{\partial x_{m(k)}}(x_k) \right| = \max_{j=1,\ldots,n} \left| \frac{\partial F}{\partial x_j}(x_k) \right|,
\]
\[
h_k[j] = \begin{cases} 
-\frac{F(x_k)}{|F'(x_k)|} & \text{if } j = m(k), \\
0 & \text{if } j \neq m(k), 
\end{cases}
\]
and
\[
x_{k+1} = x_k + h_k.
\]
Then, the sequence \(\{x_k\}\) remains in \(U_0\) for all \(k \geq 0\) and converges to a zero \(x^* \in U_0\) of function \(F\).
Moreover, $\nabla F(x^*) \neq 0$ unless $\|x^* - x_0\|_\infty = t^*$. Furthermore, the following estimates hold for all $k \geq 0$:

$$
\|x_{k+1} - x_k\|_\infty \leq \frac{M}{2 \|\nabla F(x_k)\|_\infty} \|x_k - x_{k-1}\|_\infty^2 \\
\leq t_{k+1} - t_k \leq \left(\frac{\delta}{2}\right)^k \left(\frac{2}{p_0}\right)^{2k-1} \eta,
$$

and

$$
\|x_k - x^*\|_\infty \leq \frac{M}{2 \|\nabla F(x_k)\|_\infty} \|x_k - x_{k-1}\|_\infty^2 \\
\leq t^* - t_k \leq \left(\frac{\delta}{2}\right)^k \left(\frac{2}{p_0}\right)^{2k-1} \eta \left(1 - (\frac{2}{p_0})^{2k}\right) (2 \frac{1}{p_0} < 1),
$$

where the iteration \{t_k\} is given by (2.3), for

$$
L_0 = \|\frac{\partial F}{\partial x_m(0)}(x_0)\|_\infty^{-1} M_0, \quad L = \|\frac{\partial F}{\partial x_m(0)}(x_0)\|_\infty^{-1} M, \\
\eta = \|\frac{\partial F}{\partial x_m(0)}(x_0)\|_\infty^{-1} |F(x_0)|.
$$

A result similar to Theorem 2.6 can be stated under analogous conditions and proof.

The advantages of our results over the corresponding ones in [5] see Section 3, Theorem 3] have already been stated in Remarks 2.5 and 2.7.

We now refer the motivated reader to Section 4 in [5] for further applications (see also [7–12]). Clearly, the applicability of the results listed in [5] has now been expanded in view of our results. More applications and other relevant work can be found in [7–12]. Maple programs for the methods mentioned here can be downloaded from [4].

We provide an example where our Theorem 2.2 can apply to solve an equation, but not the corresponding Theorem 1 in [5].

**Example 3.3.** Let $n = 2$. Here, we use the Euclidean inner product and the corresponding norm for both the vector and matrix. Choose:

$$
x_0 = (1, 1)^T, \quad \mathcal{D} = \{x : \|x - x_0\| \leq 1 - b\} \quad \text{for} \quad b \in [0, 1),
$$

and define function $F$ on $\mathcal{D}$ by

$$
F(x) = \frac{\theta_1^3 + \theta_2^3}{2} - b, \quad x = (\theta_1, \theta_2)^T.
$$

Then, the gradient $\nabla F$ of the operator $F$ is given by

$$
\nabla F(x) = \frac{3}{2} (\theta_1^2, \theta_2^2)^T.
$$

Using (2.10), (2.11), (3.1), and (3.2), we obtain the parameters:

$$
M = 3 (2 - b) \sqrt{2}, \quad M_0 = \frac{3 (3 - b) \sqrt{2}}{2}, \quad \|\nabla F(x_0)\| = \frac{3 \sqrt{2}}{2},
$$

and

$$
F(x_0) = 1 - b \quad \text{and} \quad \eta = \frac{\sqrt{2}}{3} F(x_0).
$$
We can choose the directions \( d_k \) by

\[
    d_k = \frac{\nabla F(x_k)}{\| \nabla F(x_k) \|}
\]

so that condition (2.20) is satisfied as an equality.

Then, condition (2.32) used in [5] is violated for say \( b = .6166 \), since

\[
    L = 2.7668, \quad \eta = .180736493, \quad \text{and} \quad p = L \eta = 2 \sqrt{2} (2 - b) (1 - b) = .500061729 > .5.
\]

Hence, there is no guarantee that (DNM) starting at \( x_0 \) converges to a zero \( x^\ast \) of the function \( F \).

However, our conditions hold.

We have:

\[
    L_0 = 2.3834, \quad L = 2.50910088, \quad \delta = 1.050097978.
\]

That is,

\[
    q_0 = .453486093 < .5 \quad \text{and} \quad t^{\ast\ast} = .38053712 < 1 - b = .3834.
\]

Hence, the hypotheses of Theorem 2.2 are satisfied. We found \( x^\ast = (.851140338, .851140338) \).

That is, our Theorem 2.2 guarantees the existence of a zero \( x^\ast \) in \( U_0 \) of function \( F \), obtained as the limit of (DNM) starting at \( x_0 \).

**Remark 3.4.** The results can be extended in a Hilbert space setting. Indeed, let \( F \) be a differentiable operator defined on a convex subset \( D \) of a Hilbert space \( H \) with values in \( \mathbb{R} \). Here \( x \cdot y \) denotes the inner product of elements \( x \) and \( y \) in \( H \), and \( \| x \| = (x \cdot x)^{1/2} \).

Moreover, instead of condition (2.17) or (2.20), assume:

\[
    \| d_k \| = 1,
\]

and, there exists \( \xi \in [0, 1] \) such that:

\[
    |\nabla F(x_k) \cdot d_k| \geq \xi \| \nabla F(x_k) \|.
\]

Note that in the case of (2.17), we can always set:

\[
    \xi = \frac{|\nabla F(x_k) \cdot d_k|}{\| \nabla F(x_0) \|} \leq 1.
\]

In the case of Theorems 2.2 and 2.6 set

\[
    L_0 = \frac{M_0}{\xi \| \nabla F(x_0) \|}, \quad L = \frac{M}{\xi \| \nabla F(x_0) \|}, \quad \text{and} \quad \eta = \frac{|F(x_0)|}{\xi \| \nabla F(x_0) \|}.
\]

Then, due to the proofs of Theorems 2.2 and 2.6, the results in Section 2 hold in this more general setting. A similar extension can follow for the results of this section.
Appendix

Proof of Lemma 2.1. If \( L_0 = 0 \), then for \( L > 0 \), an induction argument shows that
\[
t_{k+1} - t_k = \frac{2}{L} (2 q_0)^{2^k} \quad (k \geq 0).
\]
Therefore, we get
\[
t_{k+1} = t_1 + (t_2 - t_1) + \cdots + (t_{k+1} - t_k) = \frac{2}{L} \sum_{m=0}^{k} (2 q_0)^{2^m}
\]
and
\[
t^* = \lim_{k \to \infty} t_k = \frac{2}{L} \sum_{k=0}^{\infty} (2 q_0)^{2^k}.
\]
Clearly, this series converges, since \( k \leq 2^k \), \( 2 q_0 < 1 \), and is bounded above by
the number
\[
\frac{2}{L} \sum_{k=0}^{\infty} (2 q_0)^k = \frac{4}{L} \left( \frac{1}{2} - \frac{L}{4} \right).
\]
If \( L = 0 \), since \( 0 \leq L_0 \leq L \), we deduce: \( L_0 = 0 \), and \( t^* = t_k = \eta \) (\( k \geq 1 \)).
In the rest of the proof, we assume that \( L_0 > 0 \).
The result until estimate (2.7) follows from Lemma 1 in [2] (see also [1], [3]).
Note that, in particular, Newton–Kantorovich-type convergence condition (2.1) is given in [2] page 387, Case 3 for \( \delta \) given by (2.5). The factor \( \eta \) is missing from the left-hand side of the inequality three lines before the end of page 387.
In order for us to show (2.8), we first need the estimate:
\[
1 - \left( \frac{\delta}{2} \right)^{k+1} \leq \frac{1}{L_0} \left( 1 - \left( \frac{\delta}{2} \right)^{k-1} \frac{L}{4 L} \right) \quad (k \geq 1).
\]
For \( k = 1 \), estimate (A.1) becomes
\[
\left( 1 + \frac{\delta}{2} \right) \eta \leq \frac{4 L - L}{4 L L_0}
\]
or
\[
\left( 1 + \frac{2 L}{L + \sqrt{L^2 + 8 L_0 L}} \right) \eta \leq \frac{4 L_0 - L + \sqrt{L^2 + 8 L_0 L}}{L_0 (4 L_0 + L + \sqrt{L^2 + 8 L_0 L})}.
\]
In view of hypothesis (2.1), it suffices to show:
\[
\frac{L_0 (4 L_0 + L + \sqrt{L^2 + 8 L_0 L}) (3 L + \sqrt{L^2 + 8 L_0 L})}{(L + \sqrt{L^2 + 8 L_0 L}) (4 L_0 - L + \sqrt{L^2 + 8 L_0 L})} \leq 2 L,
\]
which is true as an equality.

Let us now assume that estimate (A.1) is true for all integers smaller than or equal to \( k \). We must show that (A.1) holds for \( k \) replaced by \( k + 1 \):
\[
1 - \left( \frac{\delta}{2} \right)^{k+2} \leq \frac{1}{L_0} \left( 1 - \left( \frac{\delta}{2} \right)^{k} \frac{L}{4 L} \right) \quad (k \geq 1)
\]
or

\[(A.2) \quad \left(1 + \delta \left(\frac{\delta}{2}\right)^k + \cdots + \left(\delta \left(\frac{\delta}{2}\right)^{k+1}\right) \eta \leq \frac{1}{L_0} \left(1 - \left(\delta \left(\frac{\delta}{2}\right)^k \frac{L}{4L}\right)\right).\]

By the induction hypothesis to show estimate (A.2), it suffices to have:

\[\frac{1}{L_0} \left(1 - \left(\delta \left(\frac{\delta}{2}\right)^{k-1} \frac{L}{4L}\right)\right) + \left(\frac{\delta}{2}\right)^{k+1} \eta \leq \frac{1}{L_0} \left(1 - \left(\delta \left(\frac{\delta}{2}\right)^k \frac{L}{4L}\right)\right),\]

or

\[\left(\frac{\delta}{2}\right)^{k+1} \eta \leq \frac{1}{L_0} \left(\left(\frac{\delta}{2}\right)^{k-1} - \left(\frac{\delta}{2}\right)^k\right) \frac{L}{4L},\]

or

\[\delta^2 \eta \leq \frac{L (2 - \delta)}{2L L_0}.

In view of hypothesis (2.1), we can show instead:

\[2 L L_0 \delta^2 \leq 2L,\]

which holds as an equality by the choice of \(\delta\) given in (2.5).

That completes the induction for estimate (A.1).

We shall show (2.8) using induction on \(k \geq 0\): estimate (2.8) is true for \(k = 0\) by (2.1), (2.3), and (2.5). In order for us to show estimate (2.8) for \(k = 1\), since

\[t_2 - t_1 = \frac{L (t_1 - t_0)^2}{2 \left(1 - L_0 t_1\right)},\]

it suffices that

\[\frac{L \eta^2}{2 \left(1 - L_0 \eta\right)} \leq \delta L \eta^2\]

or

\[\frac{L}{1 - L_0 \eta} \leq \frac{8 L L}{L + \sqrt{L^2 + 8 L_0 L}} \quad (\eta \neq 0),\]

or

\[\eta \leq \frac{1}{L_0} \left(1 - \frac{L + \sqrt{L^2 + 8 L_0 L}}{8 L}\right) \quad (L_0 \neq 0, L \neq 0).\]

But by (2.1) we have:

\[\eta \leq \frac{4}{L + 4 L_0 + \sqrt{L^2 + 8 L_0 L}}.\]

It then suffices to show that

\[\frac{4}{L + 4 L_0 + \sqrt{L^2 + 8 L_0 L}} \leq \frac{1}{L_0} \left(1 - \frac{L + \sqrt{L^2 + 8 L_0 L}}{8 L}\right)\]

or

\[\frac{L + \sqrt{L^2 + 8 L_0 L}}{8 L} \leq 1 - \frac{4 L_0}{L + 4 L_0 + \sqrt{L^2 + 8 L_0 L}}\]

or

\[\frac{L + \sqrt{L^2 + 8 L_0 L}}{8 L} \leq \frac{L + \sqrt{L^2 + 8 L_0 L}}{L + 4 L_0 + \sqrt{L^2 + 8 L_0 L}}\]

which is true as an equality by (2.2).

Let us assume that (2.8) holds for all integers smaller than or equal to \(k\). We shall show that (2.8) holds for \(k\) replaced by \(k + 1\).
Using (2.3), and the induction hypothesis, we have in turn
\[ t_{k+2} - t_{k+1} = \frac{L}{2 \left( 1 - L_0 t_{k+1} \right)} (t_{k+1} - t_k)^2 \]
\[ \leq \frac{L}{2 \left( 1 - L_0 t_{k+1} \right)} \left( \left( \frac{\delta}{2} \right)^k (2 q_0)^{2^k - 1} \eta \right)^2 \]
\[ \leq \frac{L}{2 \left( 1 - L_0 t_{k+1} \right)} \left( \left( \frac{\delta}{2} \right)^{k-1} (2 q_0)^{-1} \eta \right) \left( \left( \frac{\delta}{2} \right)^{k+1} (2 q_0)^{2^{k+1} - 1} \eta \right) \]
\[ \leq \left( \frac{\delta}{2} \right)^{k+1} (2 q_0)^{2^{k+1} - 1} \eta, \]

since
\[(A.3) \quad \frac{L}{2 \left( 1 - L_0 t_{k+1} \right)} \left( \left( \frac{\delta}{2} \right)^{k-1} (2 q_0)^{-1} \eta \right) \leq 1 \quad (k \geq 1). \]

Indeed, we can show instead of (A.3):
\[ t_{k+1} \leq \frac{1}{L_0} \left( 1 - \left( \frac{\delta}{2} \right)^{k-1} \frac{L}{4 \bar{L}} \right), \]

which is true, since by (2.7) and the induction hypotheses:
\[ t_{k+1} \leq t_k + \frac{\delta}{2} (t_k - t_{k-1}) \]
\[ \leq t_1 + \frac{\delta}{2} (t_1 - t_0) + \cdots + \frac{\delta}{2} (t_k - t_{k-1}) \]
\[ \leq \eta + \left( \frac{\delta}{2} \right) \eta + \cdots + \left( \frac{\delta}{2} \right)^{k+1} \eta \]
\[ = \frac{1 - \left( \frac{\delta}{2} \right)^{k+1}}{1 - \frac{\delta}{2}} \eta \]
\[ \leq \frac{1}{L_0} \left( 1 - \left( \frac{\delta}{2} \right)^{k-1} \frac{L}{4 \bar{L}} \right). \]

That completes the induction for estimate (2.8).

Using estimate (2.8) for \( j \geq k \), we obtain in turn for \( 2 q_0 < 1 \):
\[(A.4) \quad t_{j+1} - t_k = (t_{j+1} - t_j) + (t_j - t_{j-1}) + \cdots + (t_{k+1} - t_k) \]
\[ \leq \left( \left( \frac{\delta}{2} \right)^j (2 q_0)^{2^j - 1} + \left( \frac{\delta}{2} \right)^{j-1} (2 q_0)^{2^{j-1} - 1} + \cdots + \left( \frac{\delta}{2} \right)^k (2 q_0)^{2^k - 1} \right) \eta \]
\[ \leq \left( 1 + (2 q_0)^{2^j} + (2 q_0)^{2^{j-1}} + \cdots \right) \left( \frac{\delta}{2} \right)^k (2 q_0)^{2^k - 1} \eta \]
\[ = \left( \frac{\delta}{2} \right)^k \frac{(2 q_0)^{2^{k+1} - 1} \eta}{1 - (2 q_0)^{2^k}}. \]

Estimate (2.9) follows from (A.4) by letting \( j \to \infty \).
That completes the proof of Lemma 2.1. \( \square \)
