1. Introduction and summary. We start by considering the nature of the mapping

\[ U = \exp(iH), \]

where \( H \) is a hermitian matrix of \( n \) rows and columns, and where consequently \( U \) is a unitary matrix. We may consider \( H \) and \( U \) as points in a space of \( n^2 \) real dimensions, and then (1.1) defines a mapping of one of these spaces upon the other. As coordinates in the space \( S_H \) of matrices \( H \) we may choose the real and imaginary parts of the elements of \( H \). If

\[ H = (k_{r,\mu}) = (s_{r,\mu} + ia_{r,\mu}), \quad \nu, \mu = 1, \ldots, n, \]

(1.2)

then the values of the variables \( s_{r,\mu} \) and \( a_{r,\mu} \) determine \( H \) uniquely, and vice versa. \( S_H \) can also be considered as a vector space, since any linear combination of hermitian matrices with constant real coefficients is a hermitian matrix again. The neighborhood of a point in \( S_H \) can be defined in a natural way by introducing the Euclidean distance between two points whose Cartesian coordinates are the \( a_{r,\mu}, s_{r,\mu} \).

Since the unitary matrices \( U \) form a multiplicative group, the natural definition of a neighborhood of a point in the space \( S_U \) of matrices \( U \) must be derived from a definition of a neighborhood of the identity \( I \). We shall say that \( U \) is in a neighborhood of the matrix \( U_0 \) if \( UU_0^{-1} \) is in the neighborhood of \( I \). A neighborhood of \( I \) is defined by all those unitary matrices \( V \) for which

\[ \sum_{r,\mu=1}^{n} \left| u_{r,\mu} - \delta_{r,\mu} \right|^2 \leq \epsilon^2, \quad V = (u_{r,\mu}), \ I = (\delta_{r,\mu}). \]

(1.3)

The manifold \( S_U \) of matrices \( U \) is a part of the linear space of all matrices \( M \); this space has \( 2n^2 \) real dimensions. Since every \( U \) can be expressed by (1.1) in terms of a matrix \( H \), we may introduce the
s_{r,\mu}, a_{r,\mu} as coordinates in $S_U$. In terms of these coordinates we shall define in $S_U$ the volume element $d\tau$, which has the property of being invariant under the multiplicative group. This means that the volume of a small region $R$ in the neighborhood of a point $U_0$ on $S_U$ will be measured in terms of the volume of the region $RU_0^{-1}$ in the neighborhood of $I$. Here $RU_0^{-1}$ is defined as the set of points or unitary matrices on $S_U$ obtained from the set of matrices belonging to $R$ by right multiplication by $U_0^{-1}$. The result is

\begin{equation}
(1.4) \quad d\tau = \prod_{r<\mu} \left\{ \frac{2 \sin (\lambda_r - \lambda_\mu)/2}{\lambda_r - \lambda_\mu} \right\}^2 \prod_{r<\mu} ds_{r,\mu} \prod_{r<\mu} da_{r,\mu},
\end{equation}

where the $\lambda_r (r=1, \ldots, n)$ are the eigenvalues of $H$ and where all products are to be taken over $r, \mu = 1, \ldots, n$ with the restrictions indicated below the $H$-symbols.

It should be observed that the first product on the right-hand side of (1.4) is an entire symmetric function of the $\lambda_r$ and therefore can be expressed as an entire function of the coefficients of the characteristic equation of $H$. It becomes unity if $H$ is the null matrix.

Any other invariant volume element can differ from $d\tau$ only by a factor which is independent of $H$. Obviously, (1.4) implies the following statement:

**Lemma 1.** Let $S$ denote the region in $S_H$ which is defined by

\begin{equation}
(1.5) \quad |\lambda_r - \lambda_\mu| \leq 2\pi \quad (r, \mu = 1, \ldots, n).
\end{equation}

Then $S$ is the largest connected region of $S_H$ which contains the null matrix $H = 0$ and which is such that a full neighborhood of any interior point $H_0$ of $S$ is mapped upon a full neighborhood of $U_0 = \exp (iH_0)$ in $S_U$. This region $S$ is needed for the following

**Fourier Theorem.** Let

\begin{equation}
(1.6) \quad F(t) = (f_{r,\mu}(t)) \quad (r, \mu = 1, \ldots, n)
\end{equation}

be a matrix whose elements $f_{r,\mu}$ depend on a parameter $t$; suppose also that $F$ is defined for $-\infty < t < \infty$ and that

\begin{equation}
(1.7) \quad \int_{-\infty}^{+\infty} |f_{r,\mu}(t)| \, dt < \infty \quad (r, \mu = 1, \ldots, n).
\end{equation}

Let $H$ be any hermitian matrix represented by a point in $S$. Then

\begin{equation}
(1.8) \quad \int_{-\infty}^{\infty} F(t) \exp (iH) dt = G(H)
\end{equation}
exists, and

\[(1.9) \quad \int \int_G \exp(-itH) d\tau = L_n F(t),\]

where the scalar \(L_n\) depends on \(n\) but not on \(H\) or \(F\).

If the integral in (1.9) does not converge absolutely, it may be necessary to prescribe an appropriate method of evaluation. As a supplement to the Fourier theorem we have the

**Plancherel theorem. If the elements \(f_{r,\mu}\) are \(L^2\), then**

\[(1.10) \quad \text{trace} \int_{-\infty}^{\infty} F^*(t)F(t) dt = L_n^{-1} \text{trace} \int \int G^*(H)G(H) d\tau,\]

where the asterisk denotes the complex conjugate of the transpose of a matrix.

Some of the properties of the matrices \(G(H)\) which arise from relation (1.8) will be given in §5. We shall show there that the elements of \(G\) are linear combinations of partial derivatives of unitary invariants of \(\tau\) (the partial derivatives are taken with respect to the elements of \(H\)). In §5 we also define these unitary invariants and give the partial differential equations which they satisfy.

2. Computation of the volume element. Consider a matrix \(H+dH\), where

\[(2.1) \quad dH = (ds_{\nu, \mu}) + i(da_{\nu, \mu}) \quad (\nu, \mu = 1, \ldots, n),\]

\[
ds_{\nu, \mu} = ds_{\mu, \nu}, \quad da_{\nu, \mu} = -da_{\mu, \nu}.\]

Now we proceed to compute the quantity

\[(2.2) \quad \exp (iH + idH) \exp (-iH).\]

The terms in (2.2) that are linear in \(dH\) are given by

\[(2.3) \quad \text{id}V = idH - (1/2!) [idH, iH] + (1/3!) [[[idH, iH], iH], iH] + \cdots \]

(see [1]), where, for any matrices \(A, B,\)

\[(2.4) \quad [A, B] = AB - BA, \quad [[A, B], B] = AB^2 - 2BAB + B^2A, \ldots.\]

The matrix \(dV\) is hermitian; if we write

\[(2.5) \quad dV = (d\sigma_{\nu, \mu}) + i(d\alpha_{\nu, \mu}) \quad (\nu, \mu = 1, \ldots, n)\]

then the \(n^2\) variables \(d\sigma_{\nu, \mu}\) \((\nu \leq \mu)\) and \(d\alpha_{\nu, \mu}\) \((\nu < \mu)\) become linear functions of the \(n^2\) variables \(ds_{\nu, \mu}\) \((\nu \leq \mu)\) and \(da_{\nu, \mu}\) \((\nu < \mu)\).
The determinant $D$ of these $n^2$ linear functions is the factor of
$\prod ds_{r,\mu} \prod da_{r,\mu}$ in equation (1.4) times another factor which is a
power of $i$.

We can determine $D$ by diagonalizing $H$. Then the right-hand side
in (2.3) can be summed explicitly, and a lengthy but straightforward
computation leads directly to (1.4).

3. The Fourier theorem. We proceed now with the proof of the
Fourier theorem stated in (1.6)—(1.9). We need the following

**Lemma 2.** Let $H = (s_{r,\mu} + ia_{r,\mu})$ be a hermitian matrix. Let
\begin{equation}
\epsilon_{r,\mu} = 1/2, \quad (\nu \neq \mu), \quad \epsilon_{r,r} = 1,
\end{equation}
and let $\nabla_H$ be the matrix differential operator
\begin{equation}
\nabla_H = \left( \epsilon_{r,\mu} \frac{\partial}{\partial s_{r,\mu}} + i \epsilon_{r,\mu} \frac{\partial}{\partial a_{r,\mu}} \right).
\end{equation}

Then we have
\begin{equation}
e^{itH} = \sum_{r=1}^{n} e^{i\lambda_r t} \nabla_H \lambda_r,
\end{equation}
where the $\lambda_r$ are the eigenvalues of $H$. In applying $\nabla_H$ to any function $\lambda$
of the variables $s_{r,\mu}(\nu \leq \mu)$, and $a_{r,\mu}(\nu < \mu)$, it is to be understood that
\begin{equation}
\frac{\partial \lambda}{\partial s_{r,\mu}} = \frac{\partial \lambda}{\partial s_{\mu,r}}, \quad \frac{\partial \lambda}{\partial a_{r,\mu}} = - \frac{\partial \lambda}{\partial a_{\mu,r}}.
\end{equation}

We shall prove Lemma 2 by using a formula due to Sylvester. Let
\begin{equation}
P(\lambda) = | \lambda I - H |
\end{equation}
be the characteristic polynomial of $H$. Its roots are the eigenvalues
$\lambda_r$ of $H$, and we put
\begin{equation}
\frac{dP(\lambda)}{d\lambda} = P'(\lambda), \quad p_r = P'(\lambda_r) \quad (r = 1, \ldots, n),
\end{equation}
\begin{equation}
P_r(\lambda) = P(\lambda)/(\lambda - \lambda_r).
\end{equation}
Then we have
\begin{equation}
e^{itH} = \sum_{r=1}^{n} e^{i\lambda_r t} \frac{P_r(H)}{p_r},
\end{equation}

\* I am indebted to Professor B. Friedman for his simple derivation of (3.3) from
(3.7), which is used in the proof of this lemma.
provided that the λᵢ are different from each other; in this case, (3.7) can be proved easily by transforming H into a diagonal matrix. But even if we pass to the limit and several of the λᵢ become equal, (3.7) makes sense, as we shall prove later from equation (3.12).

We shall first prove (3.3) for the case where all the λᵢ are different from each other. We proceed as follows:

Let \( v = 1, \ldots, n \), and let

\[
(3.8) \quad x^{(v)} = (x_1^{(v)}, \ldots, x_n^{(v)})
\]

be the set of orthonormal eigenvectors of H such that \( x^{(v)} \) belongs to \( \lambda_v \). We consider \( x^{(v)} \) as a matrix of one column. The transpose and complex conjugate vector of \( x^{(v)} \) will be denoted by \( x^{(v)*} \); it is a matrix of one row. The inner product \( (x^{(v)*}, x^{(μ)}) \) equals \( δ_{v,μ} \), where \( δ_{v,μ} \) is the Kronecker symbol. If we put

\[
(3.9) \quad P_v(H)/p_v = H_v,
\]

then

\[
(3.10) \quad H_v x^{(μ)} = δ_{v,μ} x^{(μ)}.
\]

The matrix \( H_v \) is uniquely defined by (3.10), since if there were two matrices \( H_v \) and \( H'_v \) satisfying (3.10), then their difference \( G_v \) would satisfy

\[
(3.11) \quad G_v x^{(μ)} = 0
\]

for \( μ = 1, 2, \ldots, n \), and this is impossible if \( G_v \neq 0 \) because the \( x^{(μ)} \) span the \( n \)-dimensional space. Then from the definition (3.10) we know that the element in the \( j \)th row and in the \( k \)th column of \( H_v \) must be

\[
(3.12) \quad x_j^{(v)} \bar{x}_k^{(v)},
\]

where the bar denotes the complex conjugate quantity. (Any matrix having these elements (3.12) satisfies equation (3.10) and hence must be identical with \( H_v \).)

Now we are prepared to prove (3.3). We have

\[
(3.13) \quad (H - \lambda_v I) x^{(v)} = 0.
\]

If we differentiate with respect to \( y \), where \( y \) stands for one of the variables \( s_{v,μ}, a_{v,μ} \), we find

\[
(3.14) \quad 0 = \frac{∂}{∂y} (H - \lambda_v I) x^{(v)} = (H - \lambda_v I) \frac{∂x^{(v)}}{∂y} + \left( \frac{∂H}{∂y} - \frac{∂λ_v}{∂y} I \right) x^{(v)}.
\]
Multiplying the left side of (3.14) by \( x^{(\nu)}* \), we obtain

\[
(3.15) \quad x^{(\nu)}* \frac{\partial H}{\partial y} x^{(\nu)} = x^{(\nu)}* \frac{\partial \lambda_r}{\partial y} x^{(\nu)} = \frac{\partial \lambda_r}{\partial y}.
\]

Now \( \partial H/\partial y \) is a matrix with one or two elements different from zero. If \( y = s_{\nu,\nu} \), only one element of \( \partial H/\partial y \) equals unity and all the others vanish. If \( y = s_{\nu,\nu}, \nu \neq \mu \), two of the elements of \( \partial H/\partial y \) are unity, and if \( y = s_{\nu,\mu} \), one element is \(+i\) and one is \(-i\). Computing the left-hand side of (3.15) for each of these cases and using (3.12) as an expression for the elements of \( H_r \) in (3.9) we arrive at (3.3).

From the form (3.12) of the elements of the matrix (3.9) we can derive the following:

**Lemma 3.** Let the elements of \( H \) depend linearly on a parameter \( \rho \) in such a way that the eigenvalues of \( H \) are different from each other if \( \rho \) is sufficiently small but not equal to 0. Then \( \lim_{\rho \to 0} H_r \) exists and the moduli of its elements are not greater than unity.

**Proof.** The elements of the eigenvectors of \( H \) are of the form

\[
(3.16) \quad D_k \left\{ \sum_{k=1}^{n} D_k D_k \right\}^{-1/2},
\]

where the \( D_k \) are determinants involving the elements of \( H \) and its eigenvalues. All of these are single-valued analytic functions of a fractional power \( \rho^{1/l} \) (\( l \) integral) in the neighborhood of \( \rho = 0 \). Not all of the \( D_k \) vanish as \( \rho \to 0 \), except at \( \rho = 0 \). Therefore, the limit of the expression (3.16) exists for \( \rho \to 0 \).

It can be shown that every point in the space \( S_H \) of matrices \( H \) can be reached by a “straight line” of the type described in Lemma 2. Since the points in \( S_H \) on which not all the \( \lambda_r \) are different from each other form an algebraic manifold, it follows that the elements of the matrix \( H_r \) are integrable bounded functions in \( S_H \).

Now we need a decomposition of \( S_H \) into a one-parameter set of manifolds \( S(\sigma) \). We proceed as follows.

**Definition.** Let \( S(\sigma) \) be the set of all points in \( S_H \) for which

\[
(3.17) \quad \text{trace } H = s_{11} + s_{22} + \cdots + s_{nn} = n\sigma
\]

is a fixed multiple of \( \sigma \). Then we have:

**Lemma 4.** \( S(0) \) is a linear subspace of \( S_H \). The transformation

\[
(3.18) \quad \tilde{H} = H + \sigma I,
\]

which maps \( S_H \) onto itself by mapping \( H \) upon \( \tilde{H} \), also maps \( S(0) \) onto
S(\sigma). We can replace the coordinates \( s_{11}, \ldots, s_{nn} \) in \( S_H \) by \( n \) linear homogeneous functions \( \sigma, \rho_1, \ldots, \rho_{n-1} \) of these coordinates; these functions are chosen such that the volume element \( d\tau \) in \( S_H \) can be written as

\[
(3.19) \quad d\tau = n^{1/2}d\tau_0 d\sigma
\]

where

\[
(3.20) \quad d\tau_0 = D \left\{ \prod_{r<\mu} (ds_{r,\mu} da_{r,\mu}) \right\} d\rho_1 d\rho_2 \cdots d\rho_{n-1},
\]

and where \( D \) denotes the first product on the right-hand side of (1.4). The value of \( D \) is the same in all points of \( H \) which can be mapped upon each other by the transformation (3.18); that is, \( D \) does not depend on \( \sigma \). Then the matrix of the substitution connecting the \( s_{11}, \ldots, s_{nn} \) and the variables \( n^{1/2} \sigma, \rho_1, \ldots, \rho_{n-1} \) can be chosen to be a real orthogonal matrix.

The proof of Lemma 4 is almost obvious. We choose a vector \( v_0 = 1/n^{1/2} (1, 1, \ldots, 1) \) and \( n-1 \) vectors \( v_1, \ldots, v_{n-1} \) which together with \( v_0 \), form the rows of an orthogonal matrix. Putting \( s = (s_{11}, \ldots, s_{nn}) \) and

\[
(3.21) \quad n^{1/2} \sigma = (v_0, s), \quad \rho_1 = (v_1, s), \ldots, \rho_{n-1} = (v_{n-1}, s)
\]

we obtain the required transformation of coordinates in \( S_H \) and the expression for \( d\tau_0 \) in (3.19). Now we have merely to show that \( \lambda_r - \lambda_n \) is independent of \( \sigma \); then the same is true for \( D \). But

\[
(3.22) \quad \lambda_r = \lambda_{r,0} + \sigma,
\]

where \( \lambda_{r,0} \) is the value derived from \( \lambda_r \) by keeping fixed all coordinates \( s_{r,\mu}, a_{r,\mu}(\nu<\mu) \) and \( \rho_1, \ldots, \rho_{n-1} \) in \( S_H \) and replacing \( \sigma \) by zero. This completes the proof of Lemma 4.

**Lemma 5.** The set of \( S(\sigma) \) of points in \( S(\sigma) \) at which not all of the \( \lambda_r \) are different from each other is given by \( \sigma = \) constant and an algebraic relation between the coordinates \( s_{r,\mu}, a_{r,\mu}(\nu<\mu) \) and \( \rho_1, \ldots, \rho_{n-1} \).

**Proof.** The discriminant of the algebraic equation for the \( \lambda_r \) is a polynomial in the coordinates of \( S_H \). It does not vanish identically for any given \( \sigma \) as a function of the \( s_{r,\mu}, a_{r,\mu}(\nu<\mu) \) and \( \rho_1, \ldots, \rho_{n-1} \), since hermitian matrices with eigenvalues different from each other can be constructed for any preassigned value of \( \sigma = (\lambda_1 + \cdots + \lambda_n)/n \).

**Lemma 6.** The elements of the matrix \( H_r \) in (3.9) do not depend on \( \sigma \) if \( s_{11}, \ldots, s_{nn} \) are replaced by \( n^{1/2} \sigma \) and \( \rho_1, \ldots, \rho_n \). They are bounded and integrable functions in every finite part of \( S_n \).
Proof. The independence of the elements of \( H \) from \( \sigma \) follows from the independence of \( \lambda_r - \lambda_\mu \) from \( \sigma \) and from (3.9). For all \( H \) for which the \( \lambda_r \) are different from each other, (3.9) also guarantees the continuity of the elements of \( H \). The rest follows from Lemma 5 (whose analogue for \( S_H \) is also true), and from Lemma 3.

Now we are ready to prove the Fourier theorem. Let

\[
(3.23) \quad \int_{-\infty}^{+\infty} F(t)e^{it\lambda}dt = B(\lambda).
\]

Then we have from (3.3) and (3.7):

\[
(3.24) \quad \int_{-\infty}^{+\infty} F(t)e^{itH}dt = \sum_{\mu=1}^{n} B(\lambda_\mu)H_\mu = G(H),
\]

where we used the notation of §1. Multiplying the right-hand side of (3.24) by

\[
(3.25) \quad e^{-itH} = \sum_{\mu=1}^{n} e^{-it\lambda_\mu}H_\mu,
\]

and observing that according to (3.12)

\[
(3.26) \quad H_\mu H_\mu = \delta_{\mu,\mu}H_\mu,
\]

we find

\[
(3.27) \quad \int_{S} \int G(H)e^{-itH}d\tau = \sum_{\mu=1}^{n} \int_{S} B(\lambda_\mu)e^{-it\lambda_\mu}H_\mu d\tau.
\]

By applying Lemma 4 and Lemma 6 to (3.27) we find with \( \lambda_{r,0} = \lambda_r - \sigma \),

\[
(3.28) \quad \int_{S} \int G(H)e^{-itH}d\tau = \sum_{\mu=1}^{n} n^{1/2} \int_{S_0} H_\mu d\tau_0 \int_{-\infty}^{\infty} d\sigma \{ B(\lambda_{r,0} + \sigma) \exp \{ -it(\lambda_{r,0} + \sigma) \} \}
\]

where \( S_0 \) is the part of the space \( S(0) \) of Lemma 4 that lies within the part \( S \) of \( S_H \) defined in the Lemmas in §1. It should be noted that if \( H_0 \) is a point of \( S_0 \), then \( S \) contains all the points \( H_0 + \sigma I \) for \( -\infty < \sigma < \infty \), and, conversely, if \( H \) is in \( S \), then there exists a uniquely determined matrix \( H_0 \) (with trace zero) in \( S_0 \) and uniquely determined value of \( \sigma \) such that \( H = H_0 + \sigma I \).

By applying the ordinary Fourier theorem to (3.28) and using the identity
we find

\[(3.30) \int \int_S G(H)e^{itH}d\tau = F(t)2\pi n^{1/2} \int_{S_0} d\tau_0.\]

This is the Fourier theorem (1.9) with

\[(3.31) L_n = 2\pi n^{1/2} \int_{S_0} d\tau_0 = 2\pi n^{1/2} V_{n,0},\]

where \( V_{n,0} \) is the volume of \( S_0 \), computed from the volume element \( d\tau_0 \) of Lemma 4.

The problem of computing \( V_{n,0} \) seems to be a difficult one if \( n > 2 \). For \( n = 2 \), we find by elementary calculations that \( L_2 = (2\pi)^3 \).

4. **Plancherel theorem.** In this section we shall prove formula (1.10). We have for the left-hand side of (1.10)

\[(4.1) \sum_{\nu=1}^{n} \int_{-\infty}^{\infty} |f_{\nu,\mu}(t)|^2 dt.\]

As in (3.23), we define \( b_{\nu,\mu}(\lambda) \) by

\[(4.2) \int_{-\infty}^{\infty} e^{it\lambda} f_{\nu,\mu}(t) dt = b_{\nu,\mu}(\lambda);\]

then we find from (3.24), from \( H_\nu^* = H_\nu \), and from \( H_\nu H_\mu = \delta_{\nu,\mu} H_\nu \) that

\[(4.3) \text{trace } G^*G = \text{trace } GG^* = \sum_{\nu=1}^{n} \sum_{\nu=1}^{n} b_{\nu,\nu}(\lambda_\nu) h_{\nu,\nu}(\lambda_\nu),\]

where \( h_{\nu,\nu}^{(\nu)} \) is the element in the \( \nu \)th row and \( \nu \)th column of \( H_\nu \).

In order to compute

\[(4.4) \int \int_S \text{trace } GG^* d\tau\]

we decompose the integration [as in (3.28)] into an integration over \( S_0 \) and an integration over \( \sigma \) from \(-\infty\) to \( \infty \). Carrying out the integration with respect to \( \sigma \), and observing that \( h_{\nu,\nu}^{(\nu)} \) is independent of \( \sigma \), we find

\[(4.5) \int_{-\infty}^{\infty} b_{1,\nu}(\lambda_\nu) b_{1,\nu}(\lambda_\nu) d\sigma = \int_{-\infty}^{\infty} b_{1,\nu}(\sigma) b_{1,\nu}(\sigma) d\sigma = \gamma_{1,\nu,\nu}.\]
The $\gamma_{r,p,r}$ in (4.5) are constants which do not depend on $\nu$, that is, they are independent of the particular eigenvalue $\lambda$, which appears in the left-hand side of (4.5). Because of (4.2) the ordinary Plancherel theorem gives

\[ \gamma_{1, r, r} = 2\pi \int_{-\infty}^{\infty} |f_{1, r}(t)|^2 dt \]

for $r = p$. Using the fact that $H_1 + H_2 + \cdots + H_n = I$, that is,

\[ \sum_{r=1}^{n} h_{r, r}^{(p)} = \delta_{r, p}, \]

we find from (4.5), (4.6) and (4.7) that

\[ \int_{-\infty}^{\infty} \text{trace } GG^* d\sigma = 2\pi \int_{-\infty}^{\infty} \text{trace } F^*(t)F(t) dt. \]

By integrating the left-hand side of (4.8) over $S_0$ we arrive now at (1.10).

5. Some properties of the transformed functions. It is clear that the elements of a matrix $G(H)$ cannot be arbitrary functions of $n^2$ variables of $H$. We shall use Lemma 2 of §3 to prove that the elements of $G(H)$ can be written as derivatives of unitary invariants of $H$. For this purpose, we define first a unitary invariant $j(H)$ in the following manner: Let $U$ be any unitary matrix and let $H = (s_{r, \mu} + ia_{r, \mu})$ be a hermitian matrix. Then

\[ U^{-1}HU = \tilde{H} = (s_{r, \mu} + id_{r, \mu}) \]

is a hermitian matrix again. A one-valued function

\[ j(H) = j(s_{r, \mu}, a_{r, \mu}) \]

which is defined for all real values of the variables $s_{r, \mu}$ and $a_{r, \mu}$ is called a unitary invariant if, for any matrix $U$ and any variables $s_{r, \mu}$, $d_{r, \mu}$ derived from $U$ by means of (5.1),

\[ j(s_{r, \mu}, d_{r, \mu}) = j(s_{r, \mu}, a_{r, \mu}). \]

We state the following

**Lemma 7.** A function $j(s_{r, \mu}, a_{r, \mu})$ is a continuously differentiable unitary invariant if and only if

\[ (\nabla_H j)H - H(\nabla_H j)i = 0, \]

where $\nabla_H$ is the differential operator defined by (3.2).
The proof is based on a standard procedure. Since the space of unitary transformation is connected, a sufficient condition for a function to be a unitary invariant is that it be a invariant under infinitesimal unitary substitutions. From this remark, Lemma 7 can be derived by a brief computation. The "general" solution of (5.4) is, of course, an arbitrary sufficiently regular function of the coefficients of the characteristic equation of $H$.

Now we consider the elements $g_{\mu,\nu}$ of $G(H)$. Let $b_{\mu,\nu}$ be the elements of the matrix $B(\lambda)$ defined by (3.23). Let $\hat{b}_{\mu,\nu}$ be the indefinite integral of $b_{\mu,\nu}(\lambda)$, that is,

\begin{equation}
\frac{d\hat{b}_{\mu,\nu}}{d\lambda} = b_{\mu,\nu}.
\end{equation}

Then

\begin{equation}
\hat{b}_{\mu,\nu}(H) = \sum_{l=1}^{n} \hat{b}_{\mu,\nu}(\lambda_l)
\end{equation}

is a unitary invariant of $H$ since it is a symmetric function of its eigenvalues. From Lemma 2 of §3 and from (3.24) we find now

\begin{equation}
g_{\mu,\nu} = \sum_{l=1}^{n} \left( \frac{\partial j_{\mu,\nu}}{\partial s_{l\mu}} + i \frac{\partial j_{\mu,\nu}}{\partial a_{l\mu}} \right) \delta_{\nu,\mu},
\end{equation}

where $\delta_{\nu,\mu} = 1/2$ if $\nu \neq \mu$, and where $\delta_{\nu,\nu} = 1$. Equation (5.7) is the representation of the elements of $G$ in terms of unitary invariants of $H$ which was mentioned in the introduction.
