ISOTOPY IN 3-MANIFOLDS. III. CONNECTIVITY OF SPACES OF HOMEOMORPHISMS

D. E. SANDERSON

1. Introduction. J. H. Roberts has reported a proof that the space \( H(P) \) of homeomorphisms of the plane onto itself has exactly two components [7]. The corresponding result for three-space is proved in this paper (Roberts stated in an indirect communication to the author that he has carried out investigations along this line but does not intend to publish them). M. K. Fort proved that \( H(P) \) is locally arcwise connected [4] and Fort and E. E. Floyd published a paper in which they proved that the space of homeomorphisms of the 2-sphere onto itself is uniformly locally connected [3]. Both of these results are likewise extended in this paper to the three-dimensional analogues.

2. Definitions. All of the above-mentioned results are for the compact-open topology introduced by R. H. Fox [5]. If \( d(x, y) \) denotes the usual metric for Euclidean 3-space, \( E^3 \), and \( C \) is the cube in \( E^3 \) with center at the origin and side \( r \) (faces parallel to a fixed set of coordinate planes), then an admissible metric for the space, \( H(E) \), of homeomorphisms of \( E^3 \) onto itself under the compact-open topology is \( \rho(f, g) = \inf_{r>0} \max \{1/r, \sup_{x \in C} d(f(x), g(x)) \} \). Similarly, an admissible metric for the space, \( H(S) \), of homeomorphisms of the 3-sphere, \( S^3 \), onto itself is \( \rho(f, g) = \sup_{s \in S^3} d(f(x), g(x)) \). Since the treat-
ment of $E^3$ and $S^3$ will be separate, $d(x, y)$ will be used for the usual metric in $S^3$ as well as $E^3$ and $p(f, g)$ for the metric in $H(S)$ as well as $H(E)$.

An isotopy between homeomorphisms $f$ and $g$, defined on a space $X$ into a space $Y$, is a (continuous) mapping $G$ of the cartesian product, $X \times I$, of $X$ and the closed unit interval, $I$, into $Y$ such that $G(x, t)$ is a homeomorphism for each fixed $t \in I$, and for all $x \in X$, $G(x, 0) = f(x)$ and $G(x, 1) = g(x)$. $G$ is an $\epsilon$-isotopy on a subset $A$ of $X$ if for every point $p \in A$, the image of $p \times I$ under $G$ has diameter less than $\epsilon$. If $A = X$, $G$ is simply called an $\epsilon$-isotopy.

If $h \in H(E)$ and $f \in H(E)$, $f$ is said to be a $\delta$-approximation to $h$ on the subset $A$ of $E^3$ provided $d(f(x), h(x)) < \delta$ for all $x \in A$. If $A = E^3$, $f$ is referred to as simply a $\delta$-approximation.

In this paper, a homeomorphism $h$ of $E^3$ onto itself will be called piecewise linear if it is linear on every simplex of some rectilinear triangulation of $E^3$. An isotopy $G$ is piecewise linear if $G(x, t)$ is piecewise linear for each $t \in I$.

### 3. Preliminary lemmas

The first lemma is stated without proof since it is a direct result of Theorem 1 of [8]. Lemma 2 is an adaptation of a result given by Alexander [1] and is proved for the sake of completeness even though it is a direct consequence of Alexander's work.

**Lemma 1.** Given $\epsilon > 0$ and a homeomorphism $h$ of $E^3$ onto itself, suppose $C$ is a cube in $E^3$ and $U$ is any open set containing the boundary, $\text{Bd}(C)$, of $C$. Then there is a $\delta > 0$ such that if $f$ and $g$ are piecewise linear $\delta$-approximations to $h$ on $U$, a piecewise linear $\epsilon$-isotopy $G$ exists such that (i) $G(x, 0) = f(x)$ for $x \in E^3$, (ii) $G(x, 1) = g(x)$ for $x \in \text{Bd}(C)$, and (iii) $G(x, t) = f(x)$ for $x \in E^3 - U$ for all $t \in I$.

Once having "fitted" $f$ to $g$ along $\text{Bd}(C)$ by Lemma 1, it is a simple matter to deform $f$ slightly in a piecewise linear manner so that $f = g$ on the center of $C$ as well. Then Alexander's result can be applied to fit $f$ onto $g$ on all of $C$ as indicated in the following lemma.

**Lemma 2.** Let $\epsilon$, $h$, and $C$ be as in Lemma 1 and suppose $f$ and $g$ are piecewise linear $\delta$-approximations to $h$ on $C$ with $f = g$ on $\text{Bd}(C)$. Then if $\delta$ is sufficiently small, there is a piecewise linear $\epsilon$-isotopy $F$ such that (i) $F(x, 0) = f(x)$ for $x \in E^3$, (ii) $F(x, 1) = g(x)$ for $x \in C$, and (iii) $F(x, t) = f(x)$ for $x \in \text{Cl}[E^3 - C]$ for all $t \in I$.

**Proof.** We assume, without loss of generality, that $f = g$ on the center of $C$ as well. To apply Alexander's method, let $\phi$ be a $\gamma$-ap-
proximation to the identity on C which is the identity on \( \text{Cl}[E^3 - C] \) and the center of C. If \( x_i \) (i = 1, 2, 3) are the coordinates of any point referred to the coordinate system in which \( C = C_1 \), let \( x'_i \) denote the coordinates of its image under \( \phi \). Define an isotopy \( G \) as follows: \( G(p, 0) = p \), and if \( 0 < t \leq 1 \) and \( p \) has coordinates \( tx_i \), \( G(p, t) = q \) where \( q \) has coordinates \( tx'_i \). Thus \( G(p, t) \) is the identity outside \( C_t \) and maps \( C_t \) onto itself exactly like \( \phi \) maps \( C \) onto itself. Thus it is easily seen that \( G \) is a \( 2\gamma \)-isotopy of the identity onto \( \phi \) which is fixed outside \( C \) and is piecewise linear if \( \phi \) is. Denote the identity by \( i \).

To prove the lemma, suppose \( 0 < \gamma < e/4 \) and choose \( \gamma' \) so that for any subset \( A \) of \( C \) having diameter less than \( \gamma' \), \( h^{-1}(A) \) has diameter less than \( \gamma \). Choosing \( \delta < \min(\gamma'/2, e/4) \), it follows that \( f^{-1}g \) is a \( \gamma \)-approximation to the identity on \( C \). To see this, note that since \( g(x) = f(f^{-1}g(x)) \), and \( f \) is a \( \delta \)-approximation to \( h \), it follows that \( d(g(x), hf^{-1}g(x)) < \delta \) for all \( x \in C \). Hence, by the triangle inequality, \( d(h(x), hf^{-1}g(x)) < 2\delta < \gamma' \) and therefore \( d(x, f^{-1}g(x)) < \gamma \) by the choice of \( \gamma' \). Let \( G \) be the \( 2\gamma \)-isotopy between \( i \) and \( f^{-1}g \) obtained by Alexander's method. Then since \( \delta \) and \( \gamma \) are both less than \( e/4 \), \( F = fG \) is a piecewise linear \( e \)-isotopy which satisfies (i)–(iii).

4. The principal results.

**Theorem 1.** Given a positive number \( \epsilon \), every homeomorphism \( h \) of \( E^3 \) onto itself is \( \epsilon \)-isotopic to a piecewise linear homeomorphism.

**Proof.** Consider the cubes \( C_n \) in \( E^3 \), and choose a decreasing sequence of positive numbers \( \{ \delta_n \} \) such that \( \delta_n \) satisfies Lemma 2 for \( \epsilon/2^n \), \( h \), and \( C_n \) in place of \( \epsilon \), \( h \), and \( C \). Next, given a sequence of disjoint open sets \( \{ U_n \} \) where \( U_n \supset \text{Bd}(C_n) \), define a decreasing sequence of positive numbers \( \{ \delta'_n \} \) so that \( \delta'_n \) is less than \( \delta_n/2 \) and satisfies Lemma 1 for \( \delta_n/2 \), \( h \), \( C_n \), and \( U_n \) in place of \( \epsilon \), \( h \), \( C \), and \( U \).

Moise has proved that there exist arbitrarily close piecewise linear approximations to \( h \) [6, Theorem 2]; therefore choose a sequence \( \{ f'_n \} \) of \( \delta'_n \)-approximations. Then for each \( n \), a piecewise linear \( \delta_n/2 \)-isotopy \( G_n \) can be defined which deforms \( f'_n \) so as to agree with \( f_{n+1} \) on \( \text{Bd}(C_n) \) and is the identity outside \( U_n \). This replaces \( \{ f'_n \} \) by a sequence \( \{ f_n \} \) of piecewise linear \( \delta_n \)-approximations to \( h \), where \( f_n(x) = G_n(f'_n(x), 1) \).

Now let \( f \) be the piecewise linear homeomorphism which is equal to \( f_n \) on \( C_n - C_{n-1} \) for \( n = 1, 2, 3, \ldots \) (let \( C_0 \) be the null set). Both \( f \) and \( f_2 \) are \( \delta_1 \)-approximations to \( h \) on \( C_1 \), so by choice of \( \delta_1 \) there is a piecewise linear \( \epsilon/2 \)-isotopy \( F_1 \) which fits \( f \) to \( f_2 \) on \( C_1 \) and is the identity outside \( C_1 \). Now \( F_1(f(x), 1) \) agrees with \( f_2 \) on all of \( C_2 \). For
n > 1, if \( f' \) is the result of the first \( n - 1 \) such isotopies, then \( f' \) and 
\( f_{n+1} \) are \( \delta_n \)-approximations to \( h \) on \( C_n \), hence an \( \epsilon/2^n \)-isotopy \( F_n \) exists 
which fits \( f' \) to \( f_{n+1} \) on \( C_n \) so that it agrees with \( f_{n+1} \) on all of \( C_{n+1} \).

Define \( F \) to be the product of all the \( F_n \). That is, \( F \) is the isotopy 
which carries out the entire deformation of \( F_1 \) in the interval \( 0 \leq t \leq 1/2 \), that of \( F_2 \) in \( 1/2 \leq t \leq 3/4 \), \( F_3 \) in \( 3/4 \leq t \leq 7/8 \), etc., and \( F(x, 1) = h(x) \). Then \( F \) is an \( \epsilon \)-isotopy between \( h \) and the piecewise linear 
homeomorphism \( f \) as required by the theorem. Note that \( F \) is piece-
wise linear for \( 0 \leq t < 1 \).

**Theorem 2.** The space \( H(E) \) of homeomorphisms of \( E^3 \) onto itself 
under the compact-open topology is locally arcwise connected.

**Proof.** Note that two homeomorphisms are joined by an arc of 
diameter less than \( \epsilon \) in the compact-open topology provided there is 
an isotopy between them which is an \( \epsilon \)-isotopy on \( C_{1/\epsilon} \). A simple 
modification of Alexander's method extends the isotopy of Lemma 2 
to such an isotopy between \( f \) and \( g \).

Suppose now \( h \in H(E) \) and \( U \) is an \( \epsilon \)-neighborhood of \( h \). By 
Lemmas 1 and 2 and the above remarks, there is a positive number 
\( \delta < \epsilon/3 \) such that any two piecewise linear \( \delta \)-approximations to \( h \) on 
\( C_{1/\epsilon} \) are joined by an arc of diameter less than \( \epsilon/3 \). Let \( V \) be a \( \delta \)-
neighborhood of \( h \). Then \( h' \in V \) implies that \( \sup_{x \in C_{1/\delta}} d(h(x), h'(x)) = \gamma < \delta \). Now by Theorem 1, both \( h \) and \( h' \) are \( (\delta - \gamma) \)-isotopic (and 
a fortiori \( \epsilon/3 \)-isotopic) to piecewise linear homeomorphisms \( f \) and \( g \), 
respectively. Then, since \( C_{1/\delta} \supset C_{1/\epsilon}  \), \( f \) and \( g \) are \( \delta \)-approximations to 
\( h \) on \( C_{1/\epsilon} \) and so can be joined by an arc of diameter less than \( \epsilon/3 \). 
This proves the existence of an arc of diameter less than \( \epsilon \) joining \( h \) 
and \( h' \). Thus \( H(E) \) is locally arcwise connected.

**Theorem 3.** \( H(E) \) consists of exactly two components.

**Proof.** Isotopy preserves the Brouwer degree of a homeomorphism 
of \( E^3 \) onto itself (see Chapter 12 of [2] and also [9]). That is to say, 
if \( h \in H(E) \) is orientation preserving, so also is any member of \( H(E) \) 
isotopic to \( h \). Then the identity and the reflection in the origin are 
not isotopic since they have Brouwer degree 1 and \( -1 \), respectively. 
Every member of \( H(E) \) has Brouwer degree 1 or \( -1 \), and Theorem 2 
implies these two disjoint subsets of \( H(E) \) are open. Hence there are 
at least two components in \( H(E) \). That there are exactly two follows 
easily from Theorem 1.

Suppose \( f \) and \( g \) are two elements of \( H(E) \) having the same Brou-
wer degree. Then by Theorem 1 they are isotopic to piecewise linear 
homeomorphisms \( f' \) and \( g' \), respectively, which must be of the same
degree. Let $T$ be a 3-simplex on which both $f'$ and $g'$ are linear. Since $f'(T)$ and $g'(T)$ have the same orientation, there is an isotopy which deforms $f'$ so as to agree with $g'$ on $T$. This isotopy can then be extended to an isotopy between $f'$ and $g'$ by an application of Alexander's method to the exterior of $T$. Thus $f$ and $g$ are isotopic and therefore belong to the same component of $H(E)$. This completes the proof of the theorem.

**Theorem 4.** The space $H(S)$ of homeomorphisms of the 3-sphere, $S^3$, onto itself under the compact-open topology is uniformly locally arcwise connected.

**Proof.** Since $\rho(f, g) = \rho(fh, gh)$ in $H(S)$, it suffices to prove that $H(S)$ is locally arcwise connected at the identity, $i$.

Let $p$ be the point $(0, 0, 0, 1)$ of $S^3$ and $F(S)$ the subspace of $H(S)$ consisting of all elements $f$ for which $f(p) = p$. If $\pi$ is the stereographic projection of $S^3 - p$ from $p$ onto $E^3$, it is easily shown that $\pi f \pi^{-1}$ defines a homeomorphism of $F(S)$ onto $H(E)$. Then since $H(E)$ is locally arcwise connected, so also is $F(S)$.

Thus, given $\epsilon > 0$, choose $\delta < \epsilon/2$ such that for every $f$ of $F(S)$ in the $2\delta$-neighborhood of $i$ there is an $\epsilon/2$-isotopy between $f$ and $i$. Now, given any $h$ of $H(S)$ in the $\delta$-neighborhood of $i$, $d(h(p), p) < \delta < \epsilon/2$, therefore there is a rotation of $S^3$ defining a $\delta$-isotopy (which is also an $\epsilon/2$-isotopy) of $h$ onto an element $f$ of $F(S)$. Since $f$ is within $2\delta$ of $i$, by hypothesis on $\delta$ there exists an $\epsilon/2$-isotopy of $f$ onto $i$. Thus $h$ is $\epsilon$-isotopic to $i$. This completes the proof.

**Corollary.** Given a positive $\epsilon$, every homeomorphism of $S^3$ onto itself is $\epsilon$-isotopic to a piecewise linear homeomorphism.

**Remarks.** If it were true that every monotone mapping of $S^3$ onto itself is a limit point of $H(S)$, then the characterization of monotone mappings given by Floyd and Fort for the 2-sphere [3] could be extended to the 3-sphere. Namely, that if $Q$ is the interior of $S^3$, a mapping $f$ of $S^3$ onto itself is monotone if and only if there exists a continuous extension $g$ of $f$ such that $g$ maps $S^3 \cup Q$ onto itself and $g|Q$ is a homeomorphism of $Q$ onto $Q$. J. W. T. Youngs [10] proved the required approximation theorem for monotone mappings of $S^3$ onto itself but so far as the author knows, this has not been extended to $S^3$. On p. 96 of [11], Floyd asks what maps of $S^3$ onto itself can be so approximated.

It appears that the methods used here can be extended to more general 3-manifolds. J. H. Roberts, M. E. Hamstrom, and the author.
have obtained some results along this line but none have been published as yet.

_Added in proof._ The author reported a proof of the existence, for any \( \epsilon > 0 \), of an \( \epsilon \)-isotopy between homeomorphisms \( f \) and \( g \) of \( \mathbb{E}^3 \) if \( d(f(x), g(x)) < \delta \) for all \( x \in \mathbb{E}^3 \), provided \( \delta \) is small enough (Bull. Amer. Math. Soc. Abstract 63-4-546). Since this paper was submitted, J. M. Kister has improved and extended this result to \( \mathbb{E}^n \) and has obtained other related results (see James Kister, _Small isotopies in Euclidean spaces and 3-manifolds_, Bull. Amer. Math. Soc. vol. 65 (1959) pp. 371–373).
