Let $A : X \to Y$ be a linear mapping\(^1\) of a linear topological space $X$ into a linear topological space $Y$. Then the image $A(X)$ of $X$ is a linear subset of $Y$. Thus, if $A(X)$ contains an open subset of $Y$, there is evidently $A(X) = Y$, i.e. $A : X \to Y$ is a mapping onto $Y$\(^2\). But, if we know that $A(X) = Y$, we know also that for every $y \in Y$ there exists a solution $x \in X$ of the equation $A(x) = y$. These considerations show the importance of the following

**Problem.** Let $A : X \to Y$ be a mapping (not necessarily linear) of a topological space $X$ into a topological space $Y$. Under what conditions is $A(X)$ open in $Y$?

The aim of this paper is to give a particular solution of this problem in the case of mappings $A : X \to X$ of a Banach space $X$ into itself. It will be shown that the Fixed Point Theorems of Schauder and Brouwer may be applied to find conditions under which the image $A(X)$ of $X$ is open in $X$. The idea of the following proofs is: Suppose that $A : X \to X$ is a mapping of $X$ into itself and let $y_0 \in A(X)$. To prove that $A(X)$ contains a spherical region $S(y_0, r_0)$ in $X$ with centre $y_0$ and radius $r_0$, we take an arbitrary point $y \in S(y_0, r_0)$ and define the mapping $f(x) = x - \lambda [A(x) - y]$. Now, if it is possible to find for every $y \in S(y_0, r_0)$ a number $\lambda \neq 0$ (depending on $r_0$ and $y$) such that $f(x)$ has a fixed point $\tilde{x} = f(\tilde{x})$, then by $\lambda \neq 0$, we conclude that $y = A(\tilde{x})$ belongs to $A(X)$. Therefore $S(y_0, r_0) \subset A(X)$. In the following Theorem 1 it will be sufficient to choose $\lambda = 1$. Note that if we know that the image $A(X)$ of $X$ is closed and open in $X$, then for a connected $X$ we obtain $A(X) = X$. This last idea was used by the author in [1] and [2] to obtain some generalizations of the Fundamental Theorem of Algebra to $n$-dimensional Euclidean spaces and general Banach spaces.

1. We quote the following

**Principle of Schauder.** A continuous mapping of a closed, convex set of a Banach space $X$ into a compact subset of this set has a fixed point.\(^3\)

---

Received by the editors May 2, 1960 and, in revised form, October 20, 1960.

\(^1\) By “mapping” we always understand a continuous mapping.

\(^2\) This remark was made by the referee. It enabled the author to avoid some more complicated considerations.

\(^3\) See [3, Theorem 2].
**Definition 1.** Let $A : X \to Y$ be a mapping of a metric space $X$ into a metric space $Y$ and let $y_0 \in A(X)$. We say that $A : X \to Y$ is open at the point $y_0$ if there exists a spherical region $S(y_0, r_0)$ in $Y$ such that $S(y_0, r_0) \subseteq A(X)$.

Now let $F : X \to X$ be a mapping of a Banach space $X$ into itself and denote by

$$M(x_0, r) = \sup_{\|x - x_0\| \leq r} \|F(x) - F(x_0)\|.$$ 

**Theorem 1.** Let $F : X \to X$ be a completely continuous mapping of a Banach space $X$ into itself and let $A(x) = x - F(x)$. If, for the point $y_0 \in A(X)$, there exists a point $x_0 \in A^{-1}(y_0)$ such that

$$(1) \quad \inf_{0 < r < \infty} \frac{M(x_0, r)}{r} < 1,$$

then $A : X \to X$ is open at the point $y_0 \in A(X)$.

**Proof.** Let $f(x) = x - [A(x) - \bar{y}]$. We have

$$\|f(x) - x_0\| = \|F(x) + \bar{y} - x_0\|$$

$$\leq \|F(x) - F(x_0)\| + \|F(x_0) + \bar{y} - x_0\|$$

$$= \|F(x) - F(x_0)\| + \|y_0 - \bar{y}\|$$

where $y_0 = A(x_0)$. By (1) we can choose $r$ such that for $x$ satisfying $\|x - x_0\| \leq r$ there is $\|F(x) - F(x_0)\| \leq r_1 < r$. Thus, by (2), choosing $r_0$ such that $0 < r_0 < r - r_1$, we obtain for any $\bar{y} \in S(y_0, r_0)$ that $\|f(x) - x_0\| \leq r_1 + (r - r_1) = r$. This means that $f(x)$ maps the closed spherical region $S(x_0, r)$ into itself. Since $F(x)$ is completely continuous, $f(x) = F(x) + \bar{y}$ is also completely continuous. Thus, by the principle of Schauder, there exists a fixed point $\bar{x} = f(\bar{x})$, i.e. $A(\bar{x}) = \bar{y}$. Hence, every point $\bar{y}$ of $S(y_0, r_0)$ belongs to the image $A(X)$ of $X$ and therefore $A : X \to X$ is open at the point $y_0 \in A(X)$.

Note that if $X$ is a finite dimensional Euclidean space and $F : X \to X$ is a mapping of $X$ into itself, then $F$ is completely continuous. Thus from Theorem 1 we obtain the following

**Corollary 1.** Let $F : X \to X$ be a mapping of the $n$-dimensional Euclidean space $X$ into itself and let $A(x) = x - F(x)$. If $y_0 \in A(X)$ and if there exists a point $x_0 \in A^{-1}(y_0)$ such that $\inf_{0 < r < \infty} M(x_0, r)/r < 1$ then $A : X \to X$ is open at the point $y_0 \in A(X)$.

**Remark 1.** It is easily seen that it is possible to prove the above corollary in complete analogy with the proof of Theorem 1, by using

$\dagger$ See [4, p. 274].

$\ddagger$ $S$ denotes the closure of $S$. 
the classical Fixed Point Theorem of Brouwer instead of that of Schauder used in the proof of Theorem 1.

Note also that if $F: X \to X$ is a locally contractive mapping, i.e. a mapping such that for every point $x_0$ there exists a spherical region $S(x_0, r_0)$ and a number $\alpha = \alpha(x_0)$, $0 < \alpha < 1$, such that for every point $x$ of $S(x_0, r_0)$ there is $\|F(x) - F(x_0)\| \leq \alpha \|x - x_0\|$, then evidently $\inf_{0 < r < \infty} \frac{M(x_0, r)}{r} < \alpha < 1$ for every $x_0$ and hence by Theorem 1.

**Corollary 2.** If $F: X \to X$ is a completely continuous locally contractive mapping of a Banach space $X$ into itself, then $A: X \to X$ is open at every point $y_0 \in A(X)$ and therefore $A(X)$ is open in $X$.

**Remark 2.** Taking $F(x) = x$ and $X$ a finite dimensional Euclidean space, we see that the mapping $A(x) = x - x = 0$ is a trivial mapping and $A(X) = 0$. Thus $A(X)$ is not open at the point $0 \in A(X)$. But for $F(x) = x$ there is $M(x_0, r)/r = 1$ for every $x_0$ and every $r$ and thus the assumption (1) of Theorem 1 does not hold. This shows that the assumption (1) is, in a certain sense, a necessary assumption.

**Remark 3.** Let $A: X \to Y$ be a mapping of a metric space $X$ into a metric space $Y$ such that the condition $\{x_n\}_{n=1,2,...}$ does not contain a Cauchy (fundamental) subsequence, $x_n \in X$, implies that $\{A(x_n)\}_{n=1,2,...}$ does not contain a Cauchy subsequence. Mappings having this property are called polynomial mappings. It can be shown that if $A: X \to Y$ is a polynomial mapping of a complete metric space $X$ into a connected metric space $Y$ which is open at every point $y \in A(X) \setminus I$ where $I \neq A(X)$ is a set which does not disconnect the space $Y$, then $A(X) = Y$. Hence, by Theorem 1, we obtain that:

Let $F: X \to X$ be a completely continuous mapping of a Banach space $X$ into itself and let $A(x) = x - F(x)$. If the condition (1) holds for every point $y_0 \in A(X) \setminus I$, where $I \neq A(X)$ is a set which does not disconnect $X$ and if, in addition, $A: X \to X$ is a polynomial mapping, then $A(X) = X$.
