ON $p$-GROUPS OF CLASS THREE GENERATED BY THREE ELEMENTS$^1$,$^2$

J. R. BOEN

1. Introduction. Let $f(n, p)$ be the number of nonisomorphic groups of order $p^n$, $p$ a prime. G. Higman [1, p. 24] has suggested that $f(n, p)$ has the following form: there exists a positive integer $N$ and polynomials $f_i(p)$ with integer coefficients independent of $p$ such that $f(n, p) = f_i$ for $p \equiv i \pmod{N}$. He has proved this for $p$-groups of $\Phi$-class two [2]; the tables of $p$-groups show that it is correct for $n \leq 5$. In this paper we shall be concerned with $p$-groups of exponent $p > 3$ of class three generated by three elements and shall refer to them as "groups of our class".

Let $a$, $b$, $c$ be elements of a group, and let $H$, $K$, $L$ be subgroups. Define

$$(a, b) = a^{-1}b^{-1}ab,$$
$$(a, b, c) = ((a, b), c),$$
$$(H, K) = \text{the subgroup generated by } \{(h, k) \mid h \in H, k \in K\},$$
$$(H, H) = H',$$
$$(H, K, L) = ((H, K), L),$$
$$a^b = b^{-1}ab.$$ We also need the easily-verified Witt identity,

$$(a, b^{-1}, c)^b(b, c^{-1}, a)^c(c, a^{-1}, b)^a = 1.$$  

2. The classification.

**Theorem.** There is exactly one group of order $p^{14}$ of our class and none of larger order. There are $p + 7$ and $p + 5$ groups of our class of order $p^{13}$ for $p \equiv 1 \pmod{3}$ and $p \equiv 2 \pmod{3}$, respectively.

**Proof.** The first part is straightforward. Let $F$ be the free group on three generators and let $R$ be the normal subgroup generated by all $p$th powers and elements of the forms $((x, y, w), z)$, $((x, y), (w, z))$ where $x, y, z, w \in F$. Clearly $F/R = G$ is a group of our class. A theorem

of P. Hall [4, p. 56] and the formulae of Witt [3, p. 169] imply that
G is of order $p^{14}$. More precisely, they imply that $G/G'$, $G'/(G', G)$
and $(G', G)$ are elementary abelian of orders $p^4$, $p^3$, and $p^2$,
respectively. It follows easily that $G$ is unique and is the only group of
our class of order $>p^{13}$.

Let $G = \{ u_1, u_2, u_3 \}$ and define $s_1 = (u_2, u_3)$, $s_2 = (u_3, u_1)$, $s_3 = (u_1, u_2)$,
t_{ij} = (s_j, u_i)$ for $i, j = 1, 2, 3$. The $t_{ij}$'s are not independent, for the Witt
identity implies that $t_1t_2t_3 = 1$. Since $G$ is of class three, $G$ is meta-
abelian and $(G', G)$ is central. In fact, it is easy to see that $(G', G) = Z$,
the center of $G$.

Every group of our class is isomorphic to a quotient group of $G$. Define
two subsets of $G$ to be of equal type if they are conjugate
under the automorphism group of $G$. We now argue that the task of
classifying quotient groups of $G$ of order $p^{13}$ is equivalent to that of
counting equal-type classes of normal subgroups of $G$ of order $p$. Let
$H_1$ and $H_2$ be two such subgroups. If $H_2 = \alpha(H_1)$ where $\alpha$ is an auto-
morph of $G$, then clearly $G/H_1 \cong G/H_2$. To show the converse,
we notice first that $H_1$ and $H_2$ are central, since minimal normal sub-
groups of a $p$-group are central. Clearly $H_1$ and $H_2$ are in $\Phi(G)$, the
Frattini subgroup of $G$. Since $G$ is relatively free, i.e., the quotient
group of a free group by a fully invariant subgroup, $G/H_1 \cong G/H_2$
implies that $H_2 = \alpha(H_1)$ for $H_1, H_2$ in $\Phi(G)$ [1].

The following characterizes the central cyclic kernels of equal type.

**Lemma.** Consider $A = (a_{ij})$, a 3-square matrix over $GF(p)$. Define
the map $\phi: A \rightarrow t = \prod_{i,j} t_{ij}^a$. Let $t_1 = \phi(A_1)$ and $t_2 = \phi(A_2)$. Then \{t_1\} and
\{t_2\} are of equal type if and only if there exist elements of $GF(p)$ $p \neq 0$,
$\lambda$, and a matrix $B$ such that $A_1 = B(pA_2 + \lambda I)B^{-1}$.

**Proof.** Recalling that $G'$ is abelian and that the $t_{ij}$'s are central,
the following identities may be verified.

(i) $\left( \prod s_i^{t_s} \right) \left( \prod u_i^{s_i} s_i' \right) = \left( \prod s_i^{t_s} \right) \left( \prod u_i^{s_i} s_i' \right)$ where $s, s' \in G'$,
t, $t' \in Z$ and $s_1 = x_1y_3 - x_3y_2$, $s_2 = x_2y_1 - x_1y_2$, $s_3 = x_3y_2 - x_2y_3$.

(ii) $\left( \prod s_i^{t_s} \right) \left( \prod u_i^{s_i} s_i' \right) = \left( \prod s_i^{t_s} \right) \left( \prod u_i^{s_i} s_i' \right)$ where $s, s' \in G'$
and $t, t' \in Z$.

Let $\alpha$ be an automorphism of $G$ and suppose $\alpha(u_1) = \prod u_i^{s_i} s_i'$. Then (i) implies that $\alpha(s_i) = \prod s_i^{t_s'}$ and (ii) implies that
$\alpha(t_{ij}) = \prod s_i^{t_{ij}}$. The other $\alpha(s_i)$'s and $\alpha(t_{ij})$'s are obtained similarly.
Thus $\alpha$ induces an automorphism of $Z$ which is completely determined
by the automorphism $\alpha$ induces on $G/G'$.

Note that the cyclic subgroups of $G/G'$ form a projective plane $U$
over $GF(p)$ and that the cyclic subgroups of $Z$ form a 7-dimensional
projective space $T$. Our problem thus becomes that of classifying points of $T$ under collineations induced by collineations of $U$.

Let $\{1/1 \neq 1\}$ of $G/G'$ correspond to the point $X = (x_1, x_2, x_3)$ of $U$ and let $\{1/1 \neq 1\}$ of $G/Z$ correspond to the line $Y = (y_1, y_2, y_3)$ of $U$. Choose $YX = 0$ to be the incidence equation for points and lines of $U$ and let the equation for the collineation matrix $B$ acting on the points of $U$ be $B = (X')T$. Then it is well known that the equation for $B$ acting on the lines of $U$ is $Y = Y'B^{-1}$. From (ii), $t \neq 1$ is a commutator if and only if $A = X'TY$ where $\phi(A) = t$; i.e., if and only if $A$ is of rank one. If $A = X'TY$, then $A' = (X')TY'B^{-1} = BAB^{-1}$. The similarity transformation is linear, however, so $A' = BAB^{-1}$ regardless of rank $A$. The Witt identity implies that the scalar matrices comprise the kernel of $\phi$. Hence $A$ and $\rho A + \lambda I (\rho \neq 0)$ represent the same point of $T$ and the lemma follows. Q.E.D.

The remaining task is to find and count the canonical forms for the points of $T$. The method uses the fact that $A_1$ and $\rho A_2 + \lambda I$ are similar if and only if they have the same invariant factors. If $A(x) = x^3 + ax^2 + a_1x + a_0 = 0$ is the characteristic equation of $A$, then $(x + \lambda)^3 + \alpha a_2(x + \lambda)^2 + \alpha a_1(x + \lambda) + \alpha a_0 = 0$, where $\alpha = 1$, is the characteristic equation of $\rho A + \lambda I$. Let $K$ be the affine group in one variable over $GF(p)$. The canonical form for a cubic equation under $K$ is $x^3 + bx + c$ where $b = 0, 1$, or some fixed nonsquare. $x^3 + bx + c$ and $x^3 + b'x + c'$ are conjugate under $K$ if and only if $b = b'$ and $c^2 = (c')^2$. Hence there are $p + 5$ and $p + 3$ characteristic equations for $p \equiv 1 (mod 3)$ and $p \equiv 2 (mod 3)$, respectively.

This almost completes the count of the classes of invariant factors under $K$. A (cubic) characteristic equation corresponds to more than one similarity class if and only if it has a repeated root in $GF(p)$. Since the points of $T$ represented by scalar matrices are excluded, a characteristic equation with repeated roots in $GF(p)$ corresponds to exactly two similarity classes. It is easily shown that all our cubics with a double root in $GF(p)$ are conjugate under $K$; the same for triple roots. This gives two more classes of points of $T$ for every $p > 3$. Q.E.D.34

---

3 This work is a revision of the author's Ph.D. thesis written under the supervision of H. R. Brahana, University of Illinois, Urbana, Illinois (1959). The author wishes to express his appreciation for the helpful suggestions of H. R. Brahana and G. Higman.

4 The reader may notice that Theorem 1.2.2 [2, p. 568] implies that the number of classes of subspaces of $T$ (according to the classification of our lemma) has the form described at the beginning of this paper. Theorem 1.2.2 does not, however, yield a specific number of classes.
The counting of groups of our class of order $p^{12}$ by this method leads to the classification of similar pairs of matrices, an unsolved problem. The reader may check that our problem for two generators is easy, whereas for four generators seems unmanageable.

AN INEQUALITY FOR HERMITE POLYNOMIALS

JACK INDRITZ

It is known that the Hermite polynomials

$$H_n(x) = (-1)^n e^{x^2} \frac{d^n}{dx^n} e^{-x^2}, \quad n = 0, 1, \ldots, -\infty < x < \infty$$

satisfy an inequality

$$H_n(x) \leq c(2^nn!)^{1/2}e^{x^2/2}, \quad c \text{ constant.}$$

Erdelyi [1] states that $c = 1.086435$ will serve. It has been conjectured that the best value for $c$ is 1, and it is the purpose of this note to prove the conjecture.

As a basis for the discussion, we assume as known the following properties:

(3) $H_n(x)$ is a polynomial of degree $n$, having $n$ distinct real zeros.

(4) $H_{n+1}(x) = 2xH_n(x) - H_n'(x),$

(5) $H_n(x) - 2xH_{n-1}(x) + 2(n - 1)H_{n-2}(x) = 0, \quad n \geq 2,$

(6) $H_n''(x) - 2xH_n'(x) + 2nH_n(x) = 0,$

(7) $H_n(-x) = (-1)^n H_n(x),$

(8) $H_n'(x) = 2nH_{n-1}(x).$
