

CROSSED PRODUCTS OF SIMPLE RINGS

NOBUO NOBUSAWA

Let A be the algebra of all $q \times q$ matrices over a division ring D . Suppose there is given a group G of n automorphisms of A such that

- (i) the fixed subring S of G is a simple ring such that $[A : S] = n$ and
- (ii) GA_r coincides with the totality of all homomorphisms of the S -left module A to itself where A_r is the ring of right multiplication of elements of A .

Suppose also that there is given a factor system $\{c_{\sigma, \tau}\}$ ($\sigma, \tau \in G$) in the center K of A . Then a crossed product of A and G is defined via the same formulae as in the commutative case. (See [2].) The purpose of this note is to investigate the splitting property of a factor system by an extension of S as well as of A . This is a generalization of a well-known theorem for the commutative case as well as of a result given in [2].

To begin with, we shall consider a purely transcendental extension of A as follows. Let x_1, \dots, x_m be m variables. Let $D[x_1, \dots, x_m]$ be the polynomial ring of x_1, \dots, x_m over D . We suppose x_i lie in the center of the ring. Then the quotient division ring of $D[x_1, \dots, x_m]$ is denoted by $D(x_1, \dots, x_m)$. The existence of the quotient ring is clear from a general theory of quotient ring, or it can be proved directly as follows. Generally let Γ be a ring with no divisor of zero. Moreover suppose that for any nonzero elements a and b of Γ there exist nonzero elements a', b', a'' and b'' such that $aa' = bb'$ and $a''a = b''b$. We consider the set of formal elements $a^{-1}b$ and cd^{-1} ($a, b, c, d \in \Gamma$ and $a \neq 0, d \neq 0$). Define $a_1^{-1}b_1 = a_2^{-1}b_2$ if and only if there exist nonzero elements c and d such that $a_1c = b_1d$ and $a_2c = b_2d$. It is a good exercise to show that the above equivalent relation is well defined. Similarly, define $b_1a_1^{-1} = b_2a_2^{-1}$ if and only if there exist nonzero elements c and d such that $ca_1 = db_1$ and $ca_2 = db_2$. Also define $a^{-1}b = cd^{-1}$ if and only if $ac = bd$. To verify that this is well defined is also a good exercise. How to define the algebraic operations in this set is now almost clear. For example, $(a^{-1}b)(c^{-1}d) = (c'a)^{-1}b'd$, where $bc^{-1} = c'^{-1}b'$. Also, $a^{-1}b + c^{-1}d = (c''a)^{-1}(c''b + a''d)$, where $ac^{-1} = c''^{-1}a''$. The set is a division ring called a quotient ring of Γ and it is uniquely determined up to isomorphism. To apply this general theory to our case, we must verify that the above mentioned conditions of Γ are satisfied for $D[x_1, \dots, x_m]$. To see it, take $D[x_1]$ first. The above

Received by the editors September 10, 1968 and, in revised form, April 14, 1969.

conditions of Γ are easy consequences of the division algorithm in $D[x_1]$. The general case can be proved easily by induction. Thus $D(x_1, \dots, x_m)$ is constructed. Then we let $A(x_1, \dots, x_m)$ be the algebra of all $q \times q$ matrices over $D(x_1, \dots, x_m)$.

The next step is to extend G to an automorphism group of $A(x_1, \dots, x_m)$. We set $m = n - 1$ and let $G = \{\sigma_0 = \epsilon, \sigma_1, \dots, \sigma_m\}$. (ϵ is the identity.) We rather denote x_i by x_σ ($\sigma = \sigma_i$) and set $x_\epsilon = 1$. Now define

$$(1) \quad x_\sigma^\tau = x_\tau^{-1} x_{\sigma\tau} c_{\sigma,\tau}$$

for a given factor system $\{c_{\sigma,\tau}\}$, where we may assume without losing generality that $c_{\sigma,\epsilon} = c_{\epsilon,\sigma} = 1$. This is of course one of classical devices in the theory of factor sets. Using the identities $c_{\tau,\rho}^{-1} c_{\sigma\tau,\rho} c_{\sigma,\tau}^\rho = c_{\sigma,\tau\rho}$, we can prove that $(x_\sigma^\tau)^\rho = x_\sigma^{\tau\rho}$. Operating τ on elements of A as usual, we get automorphisms of $A(x_1, \dots, x_m)$. (The mappings τ are first defined on $D[x_1, \dots, x_m]$, and then we generalize them on $D(x_1, \dots, x_m)$ by setting $(a^{-1})^\tau = (a^\tau)^{-1}$ for a in $D[x_1, \dots, x_m]$.) Thus G is considered to be an automorphism group of $A(x_1, \dots, x_m)$. Moreover, what is more important, G is a group of outer automorphisms of $A(x_1, \dots, x_m)$ since every element except the identity of G acts nontrivially on the center $K(x_1, \dots, x_m)$ of the ring.

Now we are at the position to apply an elementary part of (outer) Galois theory of simple rings. (See [1].) If we denote the fixed subring of G by B , B is a simple ring and $[A(x_1, \dots, x_m) : B] = n$ [1, Theorem 1, p. 282]. Moreover, if we denote by u_1, \dots, u_n a basis of the S -left module A , then it is also a basis of the B -left module $A(x_1, \dots, x_m)$. The main object of constructing the Galois extension $A(x_1, \dots, x_m)/B$ was in that the factor system $\{c_{\sigma,\tau}\}$ splits in it as is seen from (1). However, the above result is still not satisfactory because B is too general. What we wish to get is a Galois extension A'/B' with B' in A in which $\{c_{\sigma,\tau}\}$ splits. The natural way to get such B' is a specialization method in a sense of algebraic geometry.

A brief discussion of specialization is as follows. Let $R\{t\}$ be a ring of all formal power series for a ring R and a variable t , i.e., elements of $R\{t\}$ are $\sum_{i=-\infty}^{\infty} r_i t^i$ where almost all r_i are supposed to be 0 for negative integers i . We define a mapping of $R\{t\}$ to R and a symbol ∞ ; map $\sum r_i t^i$ to r_0 if all $r_i = 0$ for negative i , and to ∞ otherwise. Returning to $D(x_1, \dots, x_m)$, set $t_i = x_i - 1$ ($i = 1, \dots, m$), and therefore $D(x_1, \dots, x_m) = D(t_1, \dots, t_m)$. Then embed $D(t_1, \dots, t_m)$ into the formal power series (division) ring $D\{t_1\} \cdots \{t_m\}$ in a natural way. (First embed $D(t_1)$ into $D\{t_1\}$, then $D(t_1, t_2)$ into $D\{t_1\}\{t_2\}$, and so on.) On the other hand, we can generalize the above mentioned

specialization to a case of several variables as follows. First, apply the above process to $R\{t_m\}$, where $R = D\{t_1\} \cdots \{t_{m-1}\}$. Next, map $R = R'\{t_{m-1}\}$ to R' and ∞ , where $R' = D\{t_1\} \cdots \{t_{m-2}\}$. Continuing this process in this order, we get a mapping of $D\{t_1\} \cdots \{t_m\}$ to D and ∞ . (∞ is always mapped to ∞ .) The mapping is called a specialization induced by $x_m \rightarrow 1, x_{m-1} \rightarrow 1, \dots$, and $x_1 \rightarrow 1$ (in this order). Restrict the mapping to the subset $D(x_1, \dots, x_m)$, we get a specialization of it. To extend it to $A(x_1, \dots, x_m)$, simply map each entry of a matrix to get a matrix whose entries are either elements of D or ∞ . If ∞ appears in a result, we set the result ∞ .

Now let B' be the finite image of B in the specialization. Clearly $S \subseteq B' \subseteq A$. Denote the totality of elements of B that have finite images in the specialization by $V(B)$, and the totality of elements of B that are mapped to 0 by $P(B)$. Set

$$U = \left\{ \sum_i b_i u_i \mid b_i \in V(B), i = 1, \dots, n \right\}$$

and

$$P = \left\{ \sum_i p_i u_i \mid p_i \in P(B), i = 1, \dots, n \right\}.$$

LEMMA. U is a ring and P is an ideal of U .

PROOF. To prove lemma, it is sufficient to show that $u_i b \in U$ and $u_i p \in P$, where $b \in V(B)$ and $p \in P(B)$. We need some preparation. Observing the condition (ii) of A , we see that every S -left homomorphism ϕ of A to S is expressed as $\phi = \sum a_i \sigma_i$ ($a_i \in A$) and $(a\phi)^\sigma = a\phi$ for every σ in G . Therefore, $a_1 = a_2 = \dots = a_n$, or $\phi = a_r (\sum \sigma_i)$ with an element a . Especially S -left homomorphisms which map u_j to 1 and u_i ($i \neq j$) to 0 are expressed as $v_{jr} (\sum \sigma_k)$ with some elements v_j . This implies $\text{Tr}_G(u_i v_j) = \delta_{ij}$. Returning to the proof of lemma, express $u_i b = \sum b_k u_k$ with b_k in B . Then $\text{Tr}_G(u_i b v_j) = b_j$. But $\text{Tr}_G(u_i b v_j) \in V(B)$ if $b \in V(B)$. This shows that $u_i b$ is contained in U . A similar discussion shows that $u_i p \in P$, which concludes the proof.

Lastly, we can show that x_σ are in U but not in P . For, set $x_\sigma = \sum b_i u_i$. As in above, $b_i = \text{Tr}_G(x_\sigma v_i)$, the latter being in $V(B)$ since $x_\sigma v_i$ are mapped to c_σ, v_i , namely, have finite images. Thus $x_\sigma \in U$. Clearly x_σ are not in P . Now, we consider the residue class ring $A' = U/P$. Since G induces an automorphism group of U as well as that of P , it induces an automorphism group of A' . The fixed subring of G in U/P is identified with B' . Moreover, if we denote the residue

classes represented by x_σ by x'_σ , then $x'_\sigma{}^\tau = x'_\tau{}^{-1}x'_{\sigma\tau}c_{\sigma,\tau}$ in A' . Thus we have obtained a final result.

THEOREM. *The factor system $\{c_{\sigma,\tau}\}$ splits in A'/B' .*
