A STRONGER BERTRAND'S POSTULATE
WITH AN APPLICATION TO PARTITIONS

ROBERT E. DRESSLER

Abstract. In this paper we give a stronger form of Bertrand's
postulate and use it to prove that every positive integer, except 1, 2,
4, 6, and 9, can be written as the sum of distinct odd primes.

Introduction. The purpose of this paper is to derive, in an elementary
manner, a stronger form of Bertrand's postulate and to use this stronger
form to prove the following:

Theorem. Every positive integer, except 1, 2, 4, 6, and 9 can be written
as the sum of distinct odd primes.

1. The stronger form. Bertrand's postulate states that if $p_n$ is the nth
prime then $p_{n+1} < 2p_n$ for all $n$. Hardy and Wright [2, p. 343] give a proof
of this result due to Erdős and they mention that a modification of the
proof will show that $p_{n+1} < 2p_n - 2$ for all $n > 2$. In fact, we note that one
can adapt the proof to show that for any positive integer $k$, there exists a
positive integer $M$ such that $p_{n+1} < 2p_n - k$ if $n > M$. The result we need is
this:

Lemma. $p_{n+1} < 2p_n - 10$ for all $n > 6$.

Proof. We will sketch the proof by indicating the necessary modifi-
cations in the proof which appears in [2] and we will use the same notation
as [2].

To begin with, assume there is some integer $n \geq 1000$ such that there is no
prime $q$ satisfying $n < q < 2n - 10$. For the binomial coefficient $N = \binom{2n - 10}{n}$
and any prime $p$,

$$k_p = \sum_{m=1}^{10} \left( \left\lfloor \frac{2n - 10}{p^m} \right\rfloor - \left\lfloor \frac{n}{p^m} \right\rfloor - \left\lfloor \frac{n - 10}{p^m} \right\rfloor \right)$$

where $k_p$ is defined to be the largest power of $p$ which divides $N$. For

A STRONGER BERTRAND'S POSTULATE

(2/3)n < p ≤ n we have \( k_p = 0 \) except for at most 3 primes \( p \) with \( n-9 \leq p \leq n-5 \) where \( k_p \) is 1. So

\[
\sum_{p \mid N} \log p \leq \sum_{p \leq (2/3)n} \log p + 3 \log n < (4/3)n \log 2 + 3 \log n.
\]

Also,

\[
\sum_{k_p \geq 2} k_p \log p \leq (2n - 10)^{1/2} \log(2n - 10).
\]

Thus

(*) \[ \log N \leq \frac{n}{3} \log 2 + 3 \log n + (2n - 10)^{1/2} \log(2n - 10). \]

But

\[
2^{2(n-10)} \leq (2n - 10)^{\frac{n}{3}(n - 10)}
\]

\[
= (2n - 10)^N \left( \frac{n(n - 1)(n - 2)(n - 3)(n - 4)}{(n - 5)(n - 6)(n - 7)(n - 8)(n - 9)} \right).
\]

Taking logarithms of both sides and then applying (*) gives us a contradiction. We then check the prime tables for \( n < 1000 \) to obtain our result.

2. Proof of the theorem. We first notice that from direct calculation we have that if \( n \geq 23 \) and \( n \neq 1, 2, 4, 6, 9 \) then \( n \) can be written as the sum of distinct odd primes. Suppose for some \( n > 23 \), the conclusion holds for all \( m < n, m \neq 1, 2, 4, 6, 9 \). Let \( p \) be the largest prime \( \leq n \). Then write \( n = p + (n-p) \).

Case I. If \( n-p \neq 1, 2, 4, 6, 9 \) then we are done by the lemma and the induction hypothesis, since by Bertrand's postulate it follows that \( p > n-p \) and so \( p \) cannot be a summand in any partition of \( n-p \).

Case II. If \( n-p = 1 \) then write \( n = p_1 + (p - p_1 + 1) \) where \( p_1 \) is the largest prime \( < p \). Then we have \( p - p_1 + 1 < p_1 - 9 \) by the lemma. Also \( p - p_1 + 1 \) is odd and hence \( \neq 2, 4, 6 \), and we are done if \( p - p_1 + 1 \neq 9 \). If \( p - p_1 + 1 = 9 \) then write \( n = p_2 + (p_1 - p_2 + 9) \) where \( p_2 \) is the largest prime \( < p_1 \). We have \( p_1 - p_2 + 9 < p_2 - 1 \) by the lemma and since \( p_1 - p_2 + 9 > 9 \) we are done by the induction hypothesis.

Case III. If \( n-p = 2 \) then write \( n = p_1 + (p - p_1 + 2) \). Now \( 4 \leq p - p_1 + 2 < p_1 - 8 \) and \( p - p_1 + 2 \) is even so we are done unless \( p - p_1 + 2 = 4 \) or 6. If \( p - p_1 + 2 = 4 \) write \( n = p_2 + (p_1 - p_2 + 4) \) and we have \( 8 \leq p_1 - p_2 + 4 < p_2 - 6 \) (because \( p_2 < p_1 - 2 \)). But \( p_1 - p_2 + 4 \) is even (and hence \( \neq 9 \)) and we are done. If \( p_1 - p_2 + 2 = 6 \) then write \( n = p_2 + (p_1 - p_2 + 6) \) and we have \( 10 \leq p_1 - p_2 + 6 < p_2 - 4 \) so we are done.
Case IV. If \( n - p = 4 \) then write \( n = p_1 + (p - p_1 + 4) \). We then have \( 6 \leq p - p_1 + 4 < p_1 - 6 \). Since \( p - p_1 + 4 \) is even we are done unless \( p - p_1 + 4 = 6 \). If this is the case, write \( n = p_2 + (p_1 - p_2 + 4) \). Now \( 8 \leq p_1 - p_2 + 6 < p_2 - 4 \). Also \( p_1 - p_2 + 6 \) is even (and hence \( \neq 9 \)) and we are done.

Case V. If \( n - p = 6 \) then write \( n = p_1 + (p - p_1 + 6) \). We have \( 8 \leq p - p_1 + 6 < p_1 - 4 \) and since \( p - p_1 + 6 \) is even (and hence \( \neq 9 \)) we are done.

Case VI. If \( n - p = 9 \) then write \( n = p_1 + (p - p_1 + 9) \). We have \( 9 < p - p_1 + 9 < p_1 - 1 \) and we are done.
