A KÜNNETH FORMULA FOR COPRODUCTS OF SIMPLICIAL GROUPS

ELYAHU KATZ

Abstract. Berstein [1] (and later Clark and Smith [9]) proved that over a field the homology of the coproduct of two simplicial groups is isomorphic to the coproduct of the augmented algebras obtained by taking the homology of these groups. It turns out that this result does not hold in general over the integers. However, we obtain a Künneth like formula in which the homology of the coproduct of two groups is expressed in terms of the homology of the groups.

1. Introduction. The paper consists of two results whose combination establishes the main result.

Let $R(G_i)$ be the augmented differential graded algebras over a commutative ring $R$, associated with the simplicial groups $G_i$, $i = 1, 2$. We prove that $R(G_1 \ast G_2)$ is chain homotopy equivalent to $R(G_1) \amalg R(G_2)$, where $\ast$ stands for the coproduct of the groups and $\amalg$ stands for the coproduct of differential augmented algebras (see §2).

The second result is a Künneth like formula for coproducts. More precisely $H(Z(G_1) \amalg Z(G_2))$ is expressed in terms of $H(Z(G_1))$ and $H(Z(G_2))$ and a torsion factor denoted by mult $(G_1, G_2)$ (see §4), where $Z$ is the integers.

The main result provides us with a formula in which $H(Z(G_1 \ast G_2))$ is isomorphic to the direct sum of $H(Z(G_1)) \amalg H(Z(G_2))$ and mult $(G_1, G_2)$. This can be interpreted as follows: Let $X_1$ and $X_2$ be well-pointed, connected, topological spaces. Then, $H(\Omega(X_1 \vee X_2))$ can be expressed in terms of $H(\Omega(X_1))$ and $H(\Omega(X_2))$. Our application of the latter is restricted to some trivial cases in which mult = 0. In particular, we obtain $H(\Omega(S^l \vee S^k)) \cong H(\Omega(S^l)) \amalg H(\Omega(S^k))$, $k, l > 1$.

2. An Eilenberg-Zilber theorem for coproducts. In [1] coproducts in the category of connected graded algebras were defined. This definition can be extended to differential graded algebras. For the convenience of the reader we state the definition for the more general case, explicitly. However, we start with some other definitions.

Definition 1. Let $G_1$ and $G_2$ be objects of the category of simplicial groups. Their coproduct $G_1 \ast G_2$ is defined as follows: $(G_1 \ast G_2)_n = (G_1)_n \cap (G_2)_n$.
• \((G_2)_n\), where \((G)_n\) is the group of all elements of \(G\) of degree \(n\), and \(^*\) of the right-hand side of the equation stands for the free product of groups. The degeneracy and boundary operators of \(G_1 \ast G_2\) are induced by those of \(G_1\) and \(G_2\).

**Definition 2.** The associated algebra \(R(G)\) of the simplicial group \(G\) is defined as follows: \((R(G))_n\) is the free \(R\) module generated by \((G)_n\), and the boundary operator on the generators is defined by \(\partial g = \sum_{i=0}^n (-1)^i \partial_i g, g \in (G)_n\).

**Definition 3.** Let \(A_1\) and \(A_2\) be objects of \(\mathcal{F}\) the category of augmented differential graded algebras over the ring \(R\). Their coproduct is defined by \(A_1 \amalg A_2 = R \oplus \sum_A F_A\), where \(I\) exhausts the collection of all sequences alternating on \(1\) and \(2\). If \(I = (j_1, j_2, \ldots, j_m)\), then \(F_I = F_{j_1} \otimes F_{j_2} \otimes \cdots \otimes F_{j_n}\) where \(F_{j_k}\) is the augmentation of \(A_{j_k}\). The algebra structure on \(A_1 \amalg A_2\) is induced by the algebra structures of \(A_1\) and \(A_2\) and the tensor product.

Definitions 1 and 3 extend trivially to any finite number of objects.

**Theorem 1.** Let \(G_1, G_2 \in \mathcal{F}\). Then \(R(G_1 \ast G_2)\) is chain homotopy equivalent to \(R(G_1) \amalg R(G_2)\).

In Theorem 1 we can replace \(R(\ )\) by \(RN(\ )\), the normalized chain complex of \(R(\ )\). The proof is similar to the proof of Corollary 29.4 of [6] and will be omitted.

3. **Proof of Theorem 1.** The proof of the theorem is based on the method of acyclic models (see, for example, [6]). Thus we turn to the definition of a suitable category, models and functors.

Let \(\mathcal{C}\) denote the category of finite ordered tuples of simplicial groups \((G_1, G_2, \ldots, G_m)\). A morphism from \((G_1, \ldots, G_m)\) to \((H_1, \ldots, H_n)\) is a tuple \((h_1, \ldots, h_m)\) such that \(h_i: G_i \to H_j\) is a homomorphism, \(1 \leq i \leq m, 1 \leq j \leq n\). If also \((k_1, \ldots, k_n): (H_1, \ldots, H_n) \to (K_1, \ldots, K_p)\) is a morphism in \(\mathcal{C}\), the superposition \((k_1, \ldots, k_n)(h_1, \ldots, h_m) = (l_1, \ldots, l_m)\) is defined as follows:

\[ l_i = k_j h_i : G_i \to K_i, 1 \leq t \leq m. \]

We define two functors \(\alpha, \beta: \mathcal{C} \to \mathcal{F}\). On objects,

\[ \alpha(G_1, \ldots, G_m) = R(G_1 \ast \cdots \ast G_m) \]

and on morphisms if \(h_1 \ast \cdots \ast h_m: G_1 \ast \cdots \ast G_m \to H_1 \ast \cdots \ast H_n\) is the obvious homomorphism, then \(\alpha(h_1, \ldots, h_m) = R(h_1 \ast \cdots \ast h_m)\) is the chain map induced by the simplicial homomorphism. The other functor is defined on objects by \(\beta(G_1, \ldots, G_m) = R(G_1) \amalg \cdots \amalg R(G_m)\), and on morphisms by \(\beta(h_1, \ldots, h_m) = \alpha(h_2) \amalg \cdots \amalg \alpha(h_m)\).

We choose the following models for \(\mathcal{C}\). Let \(\Delta_n\) be the standard complex with one nondegenerate element \(\delta_n\) of degree \(n\). Denote by \(M_n = F(\Delta_n)\) Milnor's free group construction on \(\Delta_n\) [7]. The models of our category are all tuples \((M_{i_1}, M_{i_2}, \ldots, M_{i_m})\) of \(M_{i_1, i_2, \ldots, i_m}\).

**Proposition 1.** \(\alpha(M_{i_1, i_2, \ldots, i_m})\) is acyclic, i.e.
From the isomorphism $F(\Delta_i) \times \cdots \times F(\Delta_m) \cong F(\Delta_i \vee \cdots \vee \Delta_m)$ which follows from the definition of the $F$ construction, we have $H(\alpha(M_{i_1}, \ldots, i_m)) = H(F(\Delta_i \vee \cdots \vee \Delta_m))$. Since $\Delta_i$ is contractible for each $k$, so is $\Delta_i \vee \cdots \vee \Delta_m$. Because of the commutativity of the order of applying the geometric realization and loop and suspension constructions, we obtain the contractibility of $F(\Delta_i \vee \cdots \vee \Delta_m) = GE(\Delta_i \vee \cdots \vee \Delta_m)$. ($G$ is the simplicial loop construction and $E$ the suspension construction. For details see [6].)

**Proposition 2.** $\beta(M_{i_1}, \ldots, i_m)$ is acyclic.

We defined $\beta(M_{i_1}, \ldots, i_m) = R(M_{i_1}) \times \cdots \times R(M_{i_m}) = R \otimes \sum \Lambda_i$, where $\Lambda_i$ stands for the following complex: $I = (j_1, \ldots, j_m)$ belongs to the collection of all sequences in the integers $1, 2, \ldots, m$, such that adjacent integers differ from each other. $\Lambda_i$ stands for $R(M_{i_1}) \otimes \cdots \otimes R(M_{i_m})$ where $R(M)$ is the augmented complex of $R(M)$. Homology commutes with direct sums. Thus we need to compute $H(\Lambda_i)$. However, because of the associativity of the tensor product and the fact that $H(R(M_k)) = 0$ for all $k$, we obtain from the Küneth formula for two complexes, that $H(\Lambda_i) = 0$. We conclude that $H(\beta(M_{i_1}, \ldots, i_m)) = R \otimes \sum H(\Lambda_i) = R$.

**Proposition 3.** $\alpha$ is representable for $l \geq 0$.

Let $\alpha: a_1 \otimes a_2 \otimes \cdots \otimes a_n \in (R(G_1 \star \cdots \star G_m)_{l})$ where $r \in R$ and $a_i \in (G_{k_i})$. Consider the maps $x_i: \Delta_i \to G_{k_i}$ such that $x_i(\delta_i) = a_i$. We denote by $k_i^{(k_i)}$ the extension of $x_i$ to $F(\Delta_i)$. Then, $\alpha(k_1^{(k_1)}, \ldots, k_n^{(k_n)})(\delta_1 \cdots \delta_l) = a_1 a_2 \cdots a_n$.

**Proposition 4.** $\beta$ is representable for $l \geq 0$.

For a given element $b_1 \otimes b_2 \otimes \cdots \otimes b_n \in R(G_1) \times \cdots \times R(G_n)$ with $b_i \in (G_{k_i})$, we define the maps $y_i: \Delta_i \to (G_{k_i})_{k_i}$ such that $y_i(\delta_i) = b_i$. The extension of $y_i$ to $F(\Delta_i)$ is denoted by $y_i^{(k_i)}$. With this notation we obtain at once that $\beta(t_1, \ldots, t_n)(\delta_1 \cdots \delta_l) = b_1 \cdots b_n$.

**Proof of Theorem 1.** Define the following maps:

$$f_0: \alpha(G_1, \ldots, G_m) \to \beta(G_1, \ldots, G_m),$$

$$g_0: \beta(G_1, \ldots, G_m) \to \alpha(G_1, \ldots, G_m),$$

by

$$f_0(r g_1 \otimes g_2 \otimes \cdots \otimes g_n) = rg_1 \otimes g_2 \otimes \cdots \otimes g_n,$$

$$g_0(r g_1 \otimes g_2 \otimes \cdots \otimes g_n) = rg_1 g_2 \cdots g_n,$$

where $r \in R$ and $g_i \in G_{k_i}$. These maps preserve augmentation, and the result now follows from the method of acyclic models.

4. A generalized Küneth formula. The classical Küneth formula for two chain complexes was extended by Mac Lane [5], Bockstein [2] and Hungerford.
Theorem (Hungerford). Let $K^1, K^2, \ldots, K^n$ be chain complexes of free abelian groups. Then

$$H_k(K^1 \otimes \cdots \otimes K^n) = \sum_{i=1}^{n-1} \sum_{p_1 + \cdots + p_n + i = k} \text{mult}^n_i (H_{p_1}(K^1), \ldots, H_{p_n}(K^n))$$

$$\oplus (H(K^1) \otimes \cdots \otimes H(K^n))_k.$$ 

In the theorem the following notation is used:

$$\text{mult}^n_i (A^1, \ldots, A^n) = H_i(L^1 \otimes \cdots \otimes L^n),$$

where $L'$ is a free resolution of the abelian group $A'$.

At this point we would like to express the homology of $Z(G_1) \amalg Z(G_2)$ in terms of the homology of $Z(G_1)$ and $Z(G_2)$. Again, the fact that homology commutes with direct sums reduces the problem to computing the homology of multiple tensor products. For this reason we introduce the following notation:

$$\text{mult} (G_1, G_2) = \sum_{n=1}^{\infty} \sum_{i=1}^{n-1} \text{mult}^n_i (H_{p_1}(G_{j_1}), \ldots, H_{p_n}(G_{j_n})), $$

where $p_1, \ldots, p_n$ are nonnegative integers and $(j_1, \ldots, j_n)$ alternate on 1 and 2. (For each $n$ there are exactly two sequences $(j_1, \ldots, j_n)$, one starting with 1 and one starting with 2.) It should be noted that the dimension of an element in $\text{mult}$ depends only on $i$ and $p_1, \ldots, p_n$.

Theorem 2.

$$H(Z(G_1) \amalg Z(G_2)) = Z \amalg H(Z(G_1)) \amalg H(Z(G_2)) \oplus \text{mult} (G_1, G_2).$$

This follows from a multiple use of Hungerford's theorem.

Theorem 1 with $R = Z$ and Theorem 2 provide us with the main result.

Theorem 3. $H(G_1 * G_2) = Z \amalg H(Z(G_1)) \amalg H(Z(G_2)) \oplus \text{mult} (G_1, G_2)$.

5. Applications. (a) For any two simplicial groups and thus also for any two topological groups $G_1$ and $G_2$ with torsion-free integral homology, we obtain from Theorem 3: $H(G_1 * G_2) = H(G_1) \amalg H(G_2)$, because $\text{mult} (G_1, G_2) = 0$.

(b) For well-pointed, connected, topological spaces $X_1$ and $X_2$, we have the following formula:

$$H(\Omega(X_1 \vee X_2)) = H(\Omega(X_1)) \amalg H(\Omega(X_2)) \oplus \text{mult} (\Omega(X_1), \Omega(X_2)).$$

We derive the above from Theorem 3 by observing that $\Omega X$ can be replaced by a topological group under quite general conditions [8], and that $G_1 * G_2$ is
of the homotopy type of $\Omega(B_{G_1} \lor B_{G_2})$ [4]. If the loop spaces of $X_1$ and $X_2$ have torsion free integral homology, we deduce, as in (a), that

$$H(\Omega(X_1 \lor X_2)) = H(\Omega(X_1)) \amalg H(\Omega(X_2)).$$

(c) A particular case of (b) is when $X_1 = S^l$, $X_2 = S^k$, $l, k > 1$. Since for $r > 1$,

$$H_n(\Omega S^r) = \begin{cases} Z, & n = 0 \pmod{r - 1}, \\ 0, & \text{otherwise}, \end{cases}$$

we get

$$H(\Omega(S^l \lor S^k)) = H(\Omega(S^l)) \amalg H(\Omega(S^k)).$$
