THE ADDITIVE INVERSE EIGENVALUE PROBLEM
AND TOPOLOGICAL DEGREE

J. C. ALEXANDER

ABSTRACT. A short proof using topological degree is given of the additive
inverse eigenvalue problem: The diagonal elements of any square complex
matrix can be altered so as to cause the altered matrix to have any
prescribed set of eigenvalues.

The (finite-dimensional) additive inverse eigenvalue problem is the follow-
ing. Given an \( n \) by \( n \) complex matrix \( M \) and a set of \( n \) complex numbers
\( \xi_1, \ldots, \xi_n \), possibly with repetitions, does there exist a diagonal matrix \( D \)
such that the eigenvalues of \( M + D \) are precisely \( \xi_1, \ldots, \xi_n \)?

The answer is yes. In fact generically in \( \xi_1, \ldots, \xi_n \), there exist \( n! \) such \( D \),
and hence there are always between 1 and \( n! \) solutions \( D \). This problem
was solved by S. Friedland after some others had obtained various partial
solutions. He has given two proofs. The first [2] is completely algebraic and
the second [4] uses some powerful results from algebraic geometry. The
purpose of this note is to give a short proof using topological degree. Degree
theory is a standard tool for many analysts and the present proof may feel
closer to home. Also, the fact that the degree is nonzero allows the use of
methods developed by Kellogg, Li, and Yorke [5], [6] and Hirsch and Smale
(unpublished) to find the solutions numerically. See [1, Theorem 4.2]. It
should also be mentioned that Friedland has solved the multiplicative inverse
eigenvalue problem (where one tries to specify the eigenvalues of \( MD \) instead
of \( M + D \)), also using degree theory [3]. An elegant general reference for
degree theory is John Milnor’s book [7].

We turn to the proof. Let \( t^n + a_1t^{n-1} + \cdots + a_n \) be the monic poly-
nomial with roots \( \xi_1, \ldots, \xi_n \). We want the characteristic polynomial of
\( M + D \) to be \( p \). Consider \( f_M : \mathbb{C}^n \rightarrow \mathbb{C}^n \) defined by
\[
f_M(D) = (\alpha_1, \ldots, \alpha_n)
\]
if
\[
det(tI - (M + D)) = t^n + a_1t^{n-1} + \cdots + a_n.
\]
If \( M = 0 \), the zero matrix, and \( D \) has entries \( d_1, d_2, \ldots, d_n \), then
It can be checked that each \( f_M \) is proper, that all \( f_M \) are properly homotopic to \( f_0 \) and that \( f_0 \) has degree \( n! \). Thus \( f_M \) also has degree \( n! \). These details can be checked, but we have chosen to proceed slightly differently by compactifying the problem and using degree defined for closed compact manifolds rather than work with proper maps.

Let complex projective space

\[
\mathbb{C}P^n = \left\{ [\alpha_0, \ldots, \alpha_n] | \alpha_i \in \mathbb{C}, \sum |\alpha_i|^2 \neq 0 \right\},
\]

where \([\alpha_0, \ldots, \alpha_n] = [\lambda \alpha_0, \ldots, \lambda \alpha_n]\) for any nonzero \( \lambda \in \mathbb{C} \). We identify \( \mathbb{C}P^n \) with the space of all nonzero complex polynomials \( \alpha_0 t^n + \alpha_1 t^{n-1} + \cdots + \alpha_n \) modulo scalar multiples. In particular we consider \( p \in \mathbb{C}P^n \). Let \( D \) have entries \( d_1, \ldots, d_n \). One-point compactify each copy of \( \mathbb{C} \) to a Riemann sphere and consider \( d_i \in \mathbb{C} \cup \{ \infty \} = S^2 \). We claim the map \( f_M \) extends to a map

\[
\tilde{f}_M : S^2 \times 
\]

\( n \) times

\[
S^2 \to \mathbb{C}P^n.
\]

To see that \( f_M \) extends, let \( M = (m_{ij}) \), and suppose \( d_i \) is large. Then

\[
f_M(D) = \det \left[ \begin{array}{cccc}
\frac{t}{d_1} - \frac{m_{11}}{d_1} - 1 & \frac{m_{12}}{d_1} & \cdots & \frac{m_{1n}}{d_1} \\
& m_{21} & t - m_{22} - d_2 & \cdots & \frac{m_{2n}}{d_1} \\
& \vdots & \vdots & \ddots & \vdots \\
& m_{n1} & m_{n2} & \cdots & t - m_{nn} - d_n \\
\end{array} \right] \in \mathbb{C}P^n.
\]

Thus if \( d_i \) (or more generally if any subset of the \( d_i \)'s) goes to infinity, the value of \( f_M(D) \) approaches a limit in \( \mathbb{C}P^n \). Note that \( f_M \) is complex analytic in both \( M \) and \( D \). Note also that if \( k \) of the \( d_i \) are equal to infinity, then the degree of the polynomial \( f_M(D) \) is \( n - k \). In particular, \( d_i \neq \infty \) for all \( i \) if degree \( f_M(D) = n \).

If \( M = 0 \), the topological degree of \( f_M \) is well known to be \( n! \). (Two sketch proofs: (i) Treating \( S^2 = \mathbb{C}P^1 \) as nonzero linear polynomials, \( f_0 : (S^2)^n \to \mathbb{C}P^n \) is multiplication of polynomials. For all factors fixed at \( 0 \cdot t + 1 \) except for one, say \( S^2 \), the map \( f_0 \) is the inclusion of \( S^2 = \mathbb{C}P^1 \) in \( \mathbb{C}P^n \). Hence the generator of \( H^2(\mathbb{C}P^n) \) maps to the generator of \( H^2(S^2) \). Using the cup product structures of \( H^*(\mathbb{C}P^n) \) and \( H^*((S^2)^n) \), we see \( H^{2n}(\mathbb{C}P^n) \to H^{2n}((S^2)^n) \) is multiplication by \( n! \). (ii) Again treating \( f_0 : (S^2)^n \to \mathbb{C}P^n \) as multiplication of polynomials, it can be checked that a polynomial \( q(t) \in \mathbb{C}P^n \) is a regular value of \( f_0 \) if and only if all its roots \( (r_1, \ldots, r_n) \) are distinct. The preimage of \( q(t) \) is the \( n! \) products

\[
\tau = (t - r_1) \cdots (t - r_n),
\]
where \((i_1, \ldots, i_n)\) is a permutation of \((1, \ldots, n)\). The local degree at each \(\pi\) is 1, so the global degree is \(n!\). The map \(f_M\) is homotopic to \(f_0\), so the degree of \(f_M\) is also \(n!\). In particular, \(f_M\) is surjective and so there exists \(D\) such that \(f_M(D) = p\).

Moreover, by Sard's Theorem a generic set of \(q \in CP^n\) are regular values of \(f_M\). The local degree of \(f_M\) at each point in the inverse image of a regular \(q\) is +1 since \(f_M\) is complex analytic. Therefore \(f_M^{-1}(q)\) has \(n!\) points if \(q\) is regular. This completes the proof.
