SIMPLIFIED $L^\infty$ ESTIMATES FOR DIFFERENCE SCHEMES
FOR PARTIAL DIFFERENTIAL EQUATIONS

WILLIAM J. LAYTON

Abstract. $L^\infty$ estimates for one-step difference approximations to the Cauchy
problem for $\frac{\partial u}{\partial t} = \frac{\partial u}{\partial x}$ are proven by means of simple $L^2$-techniques. It is
shown that, provided the difference approximation is stable in $L^2$ (and not neces-
sarily $L^\infty$) and accurate of order $r$, the error in approximating smooth solutions is
$O(h^r)$. This has been proven by Hedstrom and Thomée using Fourier multipliers
and Besov spaces. The present paper shows how convergence rates in $L^\infty$ can be
recovered using simple techniques (such as the Fourier inversion formula). The
methods of Hedstrom and Thomée give sharper results when the difference scheme
diverges. The present paper exploits the fact that estimates between $L^\infty$ and $L^1$ are
frequently easier to obtain than between $L^\infty$ and $L^\infty$.

1. Introduction. In this paper the problem of approximating solutions to the initial
value problem

$$\frac{\partial u}{\partial t} = \frac{\partial u}{\partial x}, \quad u(x, 0) = u_0(x), \quad -\infty < x < \infty,$$

by the 1-step difference scheme

$$v_{n+1}(x) = Av_n(x), \quad v_0(x) = u_0(x),$$

$$Av_n(x) = \sum_{j \in \mathbb{Z}} a_j v(x + jh), \quad \sum_{j \in \mathbb{Z}} |a_j| < \infty,$$

is considered. Here $h, k > 0, \lambda = k/h$ is held fixed and $v_n(x) \approx u(x, nk)$. A new and
simple method of proving that the pointwise error in the approximation (2) is of
optimal order is introduced. Previous methods using multiplier theory and Besov
spaces involve long calculations and delicate estimates. Those methods based upon
Sobolev's Theorem result in a suboptimal estimate for the error unless additional
smoothness is assumed. The new method uses simple $L^2$ techniques, proves optimal
orders of convergence of $v_n$ to $u$ under sharp smoothness conditions, and applies to
difference operators that are unstable in $L^\infty$. In contrast to the estimates arising
from multiplier theory, the smoothness conditions upon $u_0$ in the new method are
stated in $L^1$.

The difference scheme (2) is said to be stable in $L^p$ (1 $\leq p \leq \infty$) if

$$||A^n||_p \leq C < \infty, \quad n = 1, 2, \ldots,$$
where $C$ is a constant independent of $n$ and $\|A^n\|_{L^p}$ is the operator norm on $L^p(\mathbb{R})$. 

(2) is said to be accurate of order $r$ if, for every sufficiently smooth solution, $u(x, t)$, to (1),

$$u(x, (n + 1)k) = Au(x, nk) + O(h^{r+1}).$$

If (2) is accurate of order $r > 0$, then (2) is consistent with (1).

Part of the Lax equivalence theorem states that if (2) is stable in $L^p$ and consistent with (1) then $v_n \to u$ in $L^p$ as $h, k \to 0$. Further, it is well known that $A$ is stable in $L^2$ if and only if its symbol $a(\theta) = \sum_{j \in \mathbb{Z}} a_j e^{ij\theta}$ satisfies $|a(\theta)| \leq 1$ for $|\theta| \leq \pi$.

The question of stability and convergence of a difference scheme in $L^p$ has recently been studied by a number of people (e.g. Hedstrom [3], Serdyukova [5], Setter [6], Strang [7], Thomée [8], and the book [2] by Brenner, Thomée and Wahlbin). In Hedstrom [3] and Brenner, Thomée and Wahlbin [2] it is shown that if $A$ is stable in $L^2$, accurate of order $r$ and if $u$ is sufficiently smooth (measured in an appropriate Besov space), then $v_n \to u$ in $L^\infty$. Convergence is optimal with respect to the rate of convergence and the smoothness required of $u_0$.

These estimates require extensive use of Fourier multipliers (in particular, the Carlson-Beurling inequality) and Besov spaces. In this paper convergence estimates in the spirit of [2 and 3] are shown under different hypotheses than [2 and 3] using elementary properties of the Fourier transform and $L^2$. The techniques of [2, 3 and 8] will provide information not furnished here, i.e., the rate of growth of $\|A^n\|_{L^\infty}$ in the unstable case. Specifically, in Brenner, Thomée and Wahlbin [2] and Hedstrom [3] it is shown that if $|a(\theta)| = 1$ and $\log a(\theta)$ is an analytic function that is not linear then,

$$\|v_n\|_{L^\infty} \geq c h^{1/2} \|u_0\|, \quad c = \text{constant > 0},$$

holds for some $u_0 \in L^\infty$.

If $\hat{u}_0$ denotes the Fourier transform of $u_0$, then $v_n(x)$ may be written

$$v_n(x) = (2\pi)^{-1/2} \int_{\mathbb{R}} a(h\theta)^n \hat{u}_0(\theta) e^{ix\theta} d\theta.$$ 

In contrast to the above instability result, for $\hat{u}_0 \in L^1$ and $|a(\theta)| \leq 1$, $|v_n(x)| \leq (2\pi)^{-1/2} \|\hat{u}_0\|_{L^1}$ follows easily. Thus, if (2) is stable in $L^2$ it will be stable in $L^\infty$ for this set of initial data.

This idea of obtaining estimates between $L^\infty$ and $L^1$ is used to find the rate of convergence of $v_n$ to $u$ when $u_n$ is smooth. The smoothness requirements in $L^1$ are sharp in that $\|v_n - u\|_{L^\infty} = O(h^r)$, provided $\hat{u}_0(\theta) \to 0$ at $\pm \infty$ in $L^1$ like $\theta^{-(r+1)}$.

The following theorem is proven in this paper.

**Theorem.** Assume that the difference scheme (2) is stable in $L^2$ and accurate of order $r$. Then, for $t = nk > 0$,

$$\|u(\cdot, t) - v_n\|_{L^\infty} \leq C h^r \|u_0\|_{r+1,1},$$

where $C$ is a constant independent of $t$ and $h$.

Here the norm $\|\cdot\|_{r+1,1}$, introduced in §2, is a measure of smoothness of $u_0$ in the transform space. It is important that the theorem applies to difference schemes...
stable in $L^2$ (and not necessarily $L^\infty$) since a difference scheme for (1) is stable in $L^\infty$ only under very restrictive conditions (see Hedstrom [3], Thomée [8]).

2. Preliminaries. For $1 \leq p \leq \infty$, $L^p = L^p(\mathbb{R})$ denotes the $L^p$ space of Lebesgue measurable functions with $L^p$ norm, $\| \cdot \|_p$, defined in the usual manner (see Nikol’skii [4]), finite. Define the Fourier and inverse Fourier transform of a function $f(x), g(\theta)$ as

\[
(Ff)(\theta) = \hat{f}(\theta) = (2\pi)^{-1/2} \int_{\mathbb{R}} f(x) e^{-i\theta x} \, dx,
\]

\[
(F^{-1}g)(x) = \check{g}(x) = (2\pi)^{-1/2} \int_{\mathbb{R}} g(\theta) e^{i\theta x} \, d\theta.
\]

Then $\hat{u}$ and $\hat{v}_n$, where $u$ and $v_n$ are given by (1) and (2) respectively, satisfy

\[
(\hat{u}(\theta, t) = \exp(it\theta)\hat{u}_0(\theta), \quad \hat{v}_n(\theta) = a(h\theta)^n \hat{u}_0(\theta).
\]

The inequality

\[
|e(x)| \leq (2\pi)^{-1/2} \| \hat{e} \|_1
\]

follows easily from the Fourier inversion formula and will play a key role in the analysis that follows. The smoothness conditions will be stated in terms of the $L^{s,p}$ spaces. Define, e.g. following Chapter 9 of Nikol’skii [4], the Bessel-MacDonald potential operator $I_s$,

\[
I_s u = F^{-1} \left( (1 + |\theta|^2)^{-s/2} (F u)(\theta) \right), \quad -\infty < s < \infty.
\]

$I_s u$ can be written as an integral operator, specifically, as convolution of $u$ with the Bessel-MacDonald kernel. Define the $L^{s,p}$ norm as

\[
\| u \|_{s,p} = \| F(I_{-s} u) \|_p, \quad -\infty < s < \infty.
\]

$L^{s,p}$ is related to the Liouville classes $L^p_s$ whose norm is given by $\| I_{-s} u \|_p$ (in particular, for $p = 2$ the two coincide), see Chapter 9 of Nikol’skii [4] for the latter.

3. Proof of the Theorem. The difference scheme (2) is assumed stable and accurate of order $r$. These two conditions are equivalent to:

(i) $|a(\theta)| \leq 1$, for $|\theta| \leq \pi$, 

(ii) $a(\theta) = \exp(i\lambda \theta + \psi(\theta))$, where $\psi(\theta) = O(\theta^{r+1})$ as $\theta \to 0$, respectively.

(i) is the well-known von Neumann condition and (ii) can be found in Thomée [8].

For $t = nk$, let $e_n(x) = u(x, t) - v_n(x)$. Then, by virtue of (3),

\[
\hat{e}_n(\theta) = \left( \exp(it\theta) - a(h\theta)^n \right) \hat{u}_0(\theta).
\]

The pointwise estimate will follow from the inequality (4),

\[
(2\pi)^{1/2} |e_n(x)| \leq \| \hat{e}_n \|_1 = \int_{\mathbb{R}} \left| \exp(i\theta) - a(h\theta)^n | \hat{u}_0(\theta) \right| d\theta
\]

\[
\leq \left( \int_{[-\pi/h, \pi/h]} + \int_{\mathbb{R}\setminus[-\pi/h, \pi/h]} \right) \left| \exp(i\theta) - a(h\theta)^n | \hat{u}_0(\theta) \right| d\theta.
\]
The first integral will be estimated using accuracy (i.e. condition (ii)) and the second will converge to zero rapidly as \( h \to 0 \) because of stability and smoothness of \( u_0 \).

Consider now,

\[
\int_{\mathbb{R}\backslash[-\pi/h,\pi/h]} |\exp(i\theta) - a(h\theta)^n| |\dot{u}_0(\theta)| \, d\theta \leq 2\int_{\mathbb{R}\backslash[-\pi/h,\pi/h]} |\dot{u}_0(\theta)| \, d\theta.
\]

For \( |\theta| \geq \pi h^{-1} \) and \( s > 0 \), \( (\pi h^{-1})^{-s}(1 + |\theta|)^{s/2} \geq 1 \). Thus,

\[
\int_{\mathbb{R}\backslash[-\pi/h,\pi/h]} |\dot{u}_0(\theta)| \, d\theta \leq h^s \pi^{-s} \int_{\mathbb{R}\backslash[-\pi/h,\pi/h]} (1 + |\theta|)^{s/2} |\dot{u}_0(\theta)| \, d\theta,
\]

and the estimate

\[
\int_{\mathbb{R}\backslash[-\pi/h,\pi/h]} |\exp(i\theta) - a(h\theta)^n||\dot{u}_0(\theta)| \, d\theta \leq Ch^s \|u_0\|_{s,1}
\]

follows for any \( s, 0 \leq s < \infty \). Here, \( C = 2\pi^{-s} \) is sufficient.

To estimate the integral over \([\frac{-n}{h}, \frac{\pi}{h}]\) note that for \( t = nk > 0 \)

\[
a(h\theta)^n - \exp(i\theta) = n\psi(h\theta) \int_0^1 \exp(s(\theta i + n\psi(h\theta))) + (1 - s)\theta \, ds.
\]

Since \( |a(\theta)| \leq 1 \), \( \text{Re}(\psi(h\theta)) \leq 0 \). Thus,

\[
|\exp(i\theta) - a(h\theta)^n| \leq n |\psi(h\theta)| \leq Cnh^{s+1} |\theta|^{s+1}
\]

holds for \( 0 \leq s \leq r \). Here property (ii) has been used. Applying this estimate to the integral under consideration yields

\[
\int_{[-\pi/h,\pi/h]} |\exp(i\theta) - a(h\theta)^n||\dot{u}_0(\theta)| \, d\theta \leq Cnh^{s+1} \int_{[-\pi/h,\pi/h]} |\theta|^{s+1} |\dot{u}_0(\theta)| \, d\theta \leq Cnh^{s+1} \|u_0\|_{s+1,1}, \quad 0 \leq s \leq r.
\]

(5), (7) and (9) together imply that for any \( s, 0 \leq s \leq r \),

\[
|e_n(x)| \leq Cnh^{s+1} \|u_0\|_{s+1,1} + Ch^s \|u_0\|_{s,1}.
\]

Since \( nk = t \) and \( k/h = \lambda = \text{constant} \), the theorem follows.

4. Remarks. The same idea can be used to derive \( L^\infty \) estimates of optimal order for any one step, constant coefficient difference scheme approximating the solution to the Cauchy problem for a well-posed constant coefficient partial differential equation in \( \mathbb{R}^n \). The extension is almost immediate. A close look at the proof reveals that if \( u_0 \in L^{s+1,1} \) for any \( s, 0 \leq s \leq r \), then the error in \( L^\infty \) will be correspondingly larger—\( O(h^{s+1}) \), instead of \( O(h^r) \).
