

ON ALMOST EVERYWHERE CONVERGENCE  
 OF BOCHNER-RIESZ MEANS IN HIGHER DIMENSIONS

MICHAEL CHRIST

ABSTRACT. In  $\mathbf{R}^n$  define  $(T_{\lambda,r}f)^\wedge(\xi) = \hat{f}(\xi)(1 - |r^{-1}\xi|^2)_+^\lambda$ . If  $n \geq 3$ ,  $\lambda > \frac{1}{2}(n-1)/(n+1)$  and  $2 \leq p < 2n/(n-1-2\lambda)$ , then  $\lim_{r \rightarrow \infty} T_{\lambda,r}f(x) = f(x)$  a.e. for all  $f \in L^p(\mathbf{R}^n)$ .

The Bochner-Riesz operators in  $\mathbf{R}^n$  are defined as  $(T_\lambda f)^\wedge(\xi) = \hat{f}(\xi)(1 - |\xi|^2)_+^\lambda$ , and the associated maximal operators are

$$T_\lambda^* f(x) = \sup_{r>0} |(f \cdot (1 - |r\xi|^2)_+^\lambda)^\vee|(x).$$

It is conjectured that, when  $\lambda > 0$ ,  $T_\lambda$  is bounded on  $L^p$  if and only if  $p'_0(\lambda) < p < p_0(\lambda)$ , where  $p_0(\lambda) = 2n/(n-1-2\lambda)$ . That the restrictions on  $p$  and  $\lambda$  are necessary was shown by Herz [7]. Carleson and Sjölin [3] proved the conjecture in dimension two. Moreover, in  $\mathbf{R}^2$  Carbery [1] has established boundedness of  $T_\lambda^*$  on  $L^p$ , and hence almost everywhere convergence of Bochner-Riesz means, for the same range of  $p$  and  $\lambda$  except for the added restriction  $p \geq 2$ . In dimensions greater than two it is known by work of C. Fefferman, Stein and Tomas [5, 6, 10] that  $T_\lambda$  is bounded on  $L^p$ , provided  $p'_0(\lambda) < p < p_0(\lambda)$  and  $\lambda > \frac{1}{2}(n-1)/(n+1)$ , but the remaining cases have not been resolved. Our principal result is

**THEOREM 1.**  $T_\lambda^*$  is bounded on  $L^p(\mathbf{R}^n)$  whenever  $2 \leq p < p_0(\lambda)$  and  $\lambda > \frac{1}{2}(n-1)/(n+1)$  for all  $n \geq 3$ .

Interest in  $L^p$  bounds for  $T_\lambda^*$  is due to the consequence

**COROLLARY.** If  $f \in L^p(\mathbf{R}^n)$ ,  $n \geq 3$ ,  $\lambda > \frac{1}{2}(n-1)/(n+1)$  and  $2 \leq p < p_0(\lambda)$ , then

$$\lim_{r \rightarrow \infty} (f \cdot (1 - |\xi/r|^2)_+^\lambda)^\vee(x) = f(x) \quad \text{a.e.}$$

The proof is based on the  $L^2$  restriction theorem of Tomas and Stein [10]. Our second result is a small extension of that theorem, related in spirit to Theorem 1.

**THEOREM 2.** Suppose  $\mu$  is a nonnegative radial measure on  $\mathbf{R}^n$ , satisfying  $\mu(\{0\}) = 0$ , and  $n \geq 2$ . Let  $\gamma = n(n-1)/(n+1)$ . Suppose  $1 < p \leq 2(n+1)/(n+3)$  and  $q = ((n-1)/(n+1))p'$ . Then a necessary and sufficient condition that the weighted norm inequality  $\|\hat{f}\|_{L^q(\mathbf{R}^n, d\mu)} \leq C\|f\|_{L^p(\mathbf{R}^n)}$  hold is that there exist  $A < \infty$  such that, for each  $0 < r < \infty$ ,  $\mu\{r < |\xi| < 2r\} \leq Ar^\gamma$ .

1980 *Mathematics Subject Classification.* Primary 42B15, 42B25.

To begin the proof of Theorem 1 let us recall (Stein and Weiss [9] and Carbery [2]) that, for any  $\varepsilon > 0$ ,

$$\|T_\lambda^* f\|_p \leq C \|Mf\|_p + C(\varepsilon) \sum_{k=1}^{\infty} 2^{-k(\lambda-1/2-\varepsilon)} \|S_{2^{-k}} f\|_p,$$

where  $M$  is the maximal operator of Hardy and Littlewood and each  $S_\delta$  is a square function defined as follows:

Consider any  $a \in C_0^\infty(\mathbf{R})$  supported in  $[-\frac{1}{2}, \frac{1}{2}]$  and satisfying  $\|D^\alpha a\|_\infty \leq 1$  for all  $0 \leq \alpha \leq 10$ . Let  $\phi(\xi) = \phi^{(\delta)}(\xi) = a(\delta^{-1}(1 - |\xi|))$ ,  $\phi_t(\xi) = \phi(t\xi)$  and

$$S_\delta f(x) = \left( \int_0^\infty |f * \check{\phi}_t|^2(x) t^{-1} dt \right)^{1/2}.$$

(To be more precise, each  $S_{2^{-k}}$  appearing in the above expression controlling  $\|T_\lambda^* f\|_p$  is defined by means of an auxiliary function  $a = a_k$  which depends on  $k$ .) Define  $p_0 = 2(n+1)/(n-1)$  and  $r = (\frac{1}{2}p_0)' = (n+1)/2$ .

LEMMA 1. *If  $S_\delta$  is defined as above, then  $\|S_\delta f\|_p \leq C(p)\delta^{1-n/2r}\|f\|_p$  for all  $2 \leq p < p_0$ .*

By summing over all  $\delta = 2^{-k}$ ,  $0 \leq k$ , we find (since  $\frac{1}{2}(n-1)/(n+1) = \frac{1}{2}n/r - \frac{1}{2}$ ) that, if  $2 \leq p < p_0$  and  $\lambda > \frac{1}{2}(n-1)/(n+1)$ , then  $T_\lambda^*$  is bounded on  $L^p$ . The full conclusion of Theorem 1 may then be obtained by interpolating with the more elementary result:  $T_\lambda^*$  is bounded on  $L^p$ , for all  $1 < p < \infty$ , once  $\lambda$  is greater than the critical index  $\frac{1}{2}(n-1)$ . (For in that case  $T_\lambda^*$  is dominated pointwise by the Hardy-Littlewood maximal operator, since

$$|((1 - |\xi|^2)_+^\lambda)^\vee(x)| \leq C(1 + |x|)^{-(n+1)/2-\lambda}.$$

Because of work of Rubio de Francia [8] and Carbery [2] one expects that the square function  $S_\delta$  should be controlled by a maximal operator. Let  $M_r h = M(h^r)^{1/r}$  for any nonnegative function  $h$ ;  $M$  always denotes the Hardy-Littlewood maximal operator.

LEMMA 2. *For any  $0 \leq h$  and  $0 < \delta \leq 1$ ,*

$$\int |S_\delta f|^2(x) h(x) dx \leq C \delta^{2-n/r} \int |f|^2(x) M_r h(x) dx.$$

Lemma 1 is an immediate corollary. That the controlling operator  $h \rightarrow M_r h$  should have such a simple form is unexpected; in dimension two the weighted inequality established by Carbery for the Bochner-Riesz multipliers involves averaging over rectangles with eccentricity  $\delta^{-1/2}$  and arbitrary orientations.

Our proof relies on an argument given by Stein (see [6]), who reduces the problem of estimating the Bochner-Riesz operators to a local one on a fixed cube, and treats the local problem by applying the  $L^2$  restriction theorem. For the local problem one has not only  $L^{p_0}$  boundedness, but boundedness of the operator in question from  $L^2$  to  $L^{p_0}$ . Our sole innovation is the observation that this stronger local information automatically carries with it a weighted inequality.

To formulate this principle abstractly we suppose that  $\mathbf{R}^n$  has been partitioned into a regular lattice of cubes of sidelengths  $2^j$ , and that  $T$  is a sublinear operator with the property that, whenever  $f$  is supported in a cube  $Q$  of the lattice,  $Tf$  is supported in a fixed dilate  $Q^*$  of  $Q$ .

LEMMA 3. Suppose  $T$  is as above,  $2 < p_0$  and  $r = (\frac{1}{2}p_0)'$ . Suppose that for any  $Q$ ,  $\|Tf\|_{p_0} \leq A\|f\|_2$  for any  $f$  supported in  $Q$ . Then for any  $f$  defined on  $\mathbf{R}^n$  and any testing function  $h \geq 0$ ,

$$\int |TF|^2(x)h(x) dx \leq CA^2 2^{jn/r} \int |f|^2(x)M_r h(x) dx.$$

PROOF. By the locality assumption it suffices to assume that  $f$  is supported in one cube  $Q$  of the lattice, and  $h$  on  $Q^*$ . By Hölder's inequality

$$\begin{aligned} \int |Tf|^2 h &\leq \left( \int |Tf|^{p_0} \right)^{2/p_0} \left( \int_{Q^*} h^r \right)^{1/r} \\ &\leq CA^2 |Q|^{1/r} \|f\|_2^2 \left( |Q^*|^{-1} \int_{Q^*} h^r \right)^{1/r} \\ &\leq CA^2 |Q|^{1/r} \|f\|_2^2 \operatorname{Inf}_{x \in Q} M_r h(x) \\ &\leq CA^2 |Q|^{1/r} \int_Q |f|^2 M_r h. \end{aligned}$$

To deduce Lemma 2, fix a cutoff function  $\eta \in C_0^\infty(\mathbf{R}^n)$ , identically one on  $\{|x| \leq 1\}$  and supported on  $\{|x| \leq 2\}$ . Suppose  $\delta > 0$  is given,  $2^{-i} > \delta \geq 2^{-i-1}$ . Let  $\zeta_i(x) = \eta(2^{-i}x)$ , and  $\zeta_j(x) = \eta(2^{-j}x) - \eta(2^{1-j}x)$  for all  $j > i$ .

Apply Lemma 3 to the vector-valued operator  $T: L^2 \rightarrow L^{p_0}(L^2[1/2, 4])$  defined by  $Tf(x, t) = (f * (\zeta_j \check{\varphi}_t))(x)$ . Let  $(\rho, \theta) \in \mathbf{R}^+ \times S^{n-1}$  denote polar coordinates. Since  $\zeta_j$  is a dilate of a fixed Schwartz function,  $j \geq i$ , and all moments of  $\hat{\zeta}_j$  vanish when  $j > i$ , routine computation gives

$$|(\hat{\zeta}_j * \varphi_t)(\rho, \theta)| \leq \begin{cases} C_N 2^{i-j} [1 + 2^i |\rho - t|]^{-N}, & \rho \in [1/4, 8], \\ C_N 2^{i-j} \delta^N (1 + \rho)^{-N}, & \text{otherwise} \end{cases}$$

for any  $N < \infty$  and any  $t \in [1/2, 4]$ . Set  $\hat{f}_0(\rho, \theta) = \hat{f}(\rho, \theta)$  for  $\rho \in [1/4, 8]$  and  $\hat{f}_0(\rho, \theta) = 0$  otherwise. Let  $f_1 = f - f_0$ .

We may now show that the parameter  $A^2$  of the lemma is at most  $C\delta^2 4^{i-j}$ . For any  $f \in L^2$ ,

$$\begin{aligned} \left\| \int_{1/2}^4 |Tf(x, t)|^2 dt \right\|_{p_0/2} &\leq \int_{1/2}^4 \|f * \zeta_j \check{\varphi}_t\|_{p_0}^2 dt \\ &\leq 2 \int_{1/2}^4 \|f_0 * \zeta_j \check{\varphi}_t\|_{p_0}^2 dt + 2 \int_{1/2}^4 \|f_1 * \zeta_j \check{\varphi}_t\|_{p_0}^2 dt. \end{aligned}$$

The first term is the main one. It is

$$\begin{aligned} &2 \int_{2^{-1}}^4 \left\| \int_{2^{-2}}^8 \int e^{ix \cdot \rho \theta} \hat{f}(\rho, \theta) (\hat{\zeta}_j * \varphi_t)(\rho, \theta) d\theta \rho^{n-1} d\rho \right\|_{p_0}^2 dt \\ &\leq C \int_{2^{-1}}^4 \int_{2^{-2}}^8 \left( \left\| \int e^{ix \cdot \rho \theta} \hat{f}(\rho, \theta) (\hat{\zeta}_j * \varphi_t)(\rho, \theta) d\theta \right\|_{p_0} d\rho \right)^2 dt \\ &\leq C \int_{2^{-1}}^4 \int_{2^{-2}}^8 \left\| \int e^{ix \cdot \rho \theta} \hat{f}(\rho, \theta) (\hat{\zeta}_j * \varphi_t)(\rho, \theta) d\theta \right\|_{p_0}^2 d\rho [1 + 2^i |\rho - t|] B(t) dt \end{aligned}$$

by the Cauchy-Schwarz inequality applied in the variable  $\rho$ , where  $B(t) = \int [1 + 2^i |\rho - t|^{-1} d\rho < C2^{-i} \approx C\delta$ . Therefore combining the above bound for  $\hat{\xi}_j * \varphi_t$  with the  $L^2$  restriction theorem of Tomas and Stein gives the bound

$$\begin{aligned} C\delta \int_{2^{-1}}^4 \int_{2^{-2}}^8 \|\hat{f}(p, \cdot)\|_{L^2(S^{n-1})}^2 2^{2(i-j)} [1 + 2^i |\rho - t|]^{1-2} d\rho dt \\ \leq C\delta^2 4^{i-j} \int_{2^{-2}}^8 \|\hat{f}(\rho, \cdot)\|_{L^2(S^{n-1})}^2 d\rho = C\delta^2 4^{i-j} \|f\|_{L^2}^2. \end{aligned}$$

A straightforward application of Plancherel's theorem and fractional integration, with no appeal to the restriction theorem, yields the same bound for the contribution of  $f_1$ .

Therefore by Lemma 3,

$$\left\langle \int_{1/2}^4 |f * \xi_j \check{\varphi}_t|^2 dt, h \right\rangle \leq C\delta^2 4^{i-j} 2^{jn/r} \langle |f|^2, M_r h \rangle.$$

Now  $n/r < 2$ , so summing the geometric series over all  $j \geq i$  gives

$$\left\langle \int_{1/2}^4 |f * \check{\varphi}_t|^2 dt, h \right\rangle \leq C\delta^{2-n/r} \langle |f|^2, M_r h \rangle.$$

In order to conclude the proof via Littlewood-Paley theory we are forced to introduce one more collection of cutoff functions. Select  $\rho \in C_0^\infty(\mathbf{R}^n)$ , radial and supported in  $\{1 \leq |\xi| \leq 3\}$  such that  $\sum_{-\infty}^\infty \rho(2^k \xi) \equiv 1$  on  $\mathbf{R}^n \setminus \{0\}$ .  $\rho_k$  denotes  $\rho(2^k \cdot)$ . Then

$$\begin{aligned} \int_0^\infty |f * \check{\varphi}_t|^2 t^{-1} dt &\leq 3 \sum_k \int_0^\infty |(f * \check{\rho}_k) * \check{\varphi}_t|^2 t^{-1} dt \\ &= 3 \sum_k \int_{2^{k-1}}^{2^{k+2}} |(f * \check{\rho}_k) * \check{\varphi}_t|^2 t^{-1} dt. \end{aligned}$$

By homogeneity and the case  $\frac{1}{2} \leq t \leq 4$ ,

$$\left\langle \int_{2^{k-1}}^{2^{k+2}} |f * \check{\rho}_k * \check{\varphi}_t|^2 t^{-1} dt, h \right\rangle \leq C\delta^{2-n/r} \langle |f * \rho_k|^2, M_r h \rangle$$

and, therefore,

$$\langle S_\delta f^2, h \rangle \leq C\delta^{2-n/r} \left\langle \sum_k |f * \check{\rho}_k|^2, M_r h \right\rangle \leq C\delta^{2-n/r} \langle |f|^2, M_r h \rangle.$$

The last inequality follows from the weighted norm theory for singular integral operators, since  $M_r h$  is an  $A_1$  weight.

**PROOF OF THEOREM 2.** The necessity of the hypothesis follows from homogeneity considerations and the fact that  $\mu\{1 < |\xi| < 2\}$  must be finite. Conversely, if  $\mu$  satisfies the hypothesis, then it is an immediate corollary of the Tomas-Stein restriction theorem that

$$\left( \int_r^{2r} |\hat{f}(\xi)|^q d\mu(\xi) \right)^{1/q} \leq CA \|f\|_p \quad \text{for any } 0 < r < \infty.$$

Let  $f_k = (\hat{f}\rho_k)^\vee$  where  $\{\rho_k\}$  are as above. Suppose  $p = 2(n+1)/(n+3)$ , so  $q = 2$ . Then

$$\int |\hat{f}(\xi)|^2 d\mu(\xi) \leq C \sum_k \int |\hat{f}_k(\xi)|^2 d\mu(\xi) \leq CA^2 \sum_k \|f_k\|_p^2.$$

But by Minkowski's inequality and the Littlewood-Paley theory,

$$\sum_k \|f_k\|_p^2 \leq \left\| \left( \sum_k |f_k|^2 \right)^{1/2} \right\|_p^2 \leq C \|f\|_p^2.$$

Since the case  $p = 1$ ,  $q = \infty$  is trivial, the case  $1 < p < 2(n+1)/(n+3)$  follows by interpolation.

REMARK. This argument is closely related to an almost-orthogonality lemma employed by the author in [4].
