SEMIPRIMENESS OF SPECIAL JORDAN ALGEBRAS
KEVIN McCrimmon

Abstract. There are important connections between radicals of a special Jordan algebra $J$ and its associative envelope $A$. For the locally nilpotent (Levitzki) radical $\mathcal{L}$, Skosyrev proved $\mathcal{L}(J) = J \cap \mathcal{L}(A)$. For the prime (Baer) radical $\mathcal{P}$, Erickson and Montgomery proved $\mathcal{P}(J) = J \cap \mathcal{P}(A)$ when $J = H(A, \ast)$ consists of all symmetric elements of an algebra $A$ with involution $\ast$. In his important work on prime Jordan algebras, Zelmanov proved $\mathcal{P}(J) = J \cap \mathcal{P}(A)$ for all linear $J$ and all associative envelopes $A$. In the present paper we extend Zelmanov's result to arbitrary quadratic Jordan algebras. In particular, we see that a special Jordan algebra is semiprime iff it has some semiprime associative envelope.

Throughout this paper we work with algebras over an arbitrary ring of scalars $\Phi$. A special Jordan algebra is a subspace $J \subset A$ of an associative algebra $A$ closed under the Jordan products
\[ x^2 = xx \quad \text{and} \quad U_x y = xyx, \]
and hence under their linearizations
\[ x \circ y = xy + yx \quad \text{and} \quad \{ xyz \} = xyz + zyx. \]

Note that in linear Jordan algebras, where $\frac{1}{2} \in \Phi$, we can recover $U_x y$ from $x^2$ since
\[ 2U_x y = x \circ (x \circ y) - x^2 \circ y. \]

As usual, the commutator or Lie product in $A$ is denoted by $[x, y] = xy - yx$. Since all our Jordan algebras live inside associative algebras, we do not need the axioms or identities characterizing abstract Jordan algebras—all identities we use are immediate consequences of the above definitions of Jordan products. We do not assume our algebras are unital, and on occasion it will be notationally convenient to use the unital hulls $\hat{A} = \Phi 1 \oplus A$, $\hat{J} = \Phi 1 \oplus J$ obtained by formally adjoining a unit.

An associative algebra $A$ is semiprime if it has no nonzero nilpotent ideals $B \lhd A$ ($B^n = 0$ for some $n$, where $B^1 = B$ and $B^{n+1} = BB^n$, for $BC$ the linear span of all elements $bc$ for $b \in B$, $c \in C$), equivalently no trivial ideals ($B^2 = 0$), equivalently no nonzero trivial elements $z$ ($zAz = 0$). There is a unique ideal $P \lhd A$ minimal among those whose quotient is semiprime; this prime or Baer radical $\mathcal{P}(A) = P$ may be recursively constructed as $\mathcal{P}(A) = \mathcal{P}(\lambda_0(A)$ for suitably large ordinal $\lambda_0$, where $\mathcal{P}_0(A) = 0$, $\mathcal{P}_{\lambda+1}(A) = \Sigma\{ B | B \lhd A$ is nilpotent modulo $\mathcal{P}(A)\}$, and $\mathcal{P}(A) = \bigcup_{\mu < \lambda} \mathcal{P}_\mu(A)$ for a limit ordinal $\lambda$.

An *ideal* \( I \triangleleft J \) in a Jordan algebra is a subspace \( I \subset J \) such that any Jordan product in \( J \) having a factor from \( I \) falls back in \( I \) (this may be succinctly phrased as \( U_j J + U_j I \subset I \)). A Jordan algebra \( J \) is *semiprime* if it has no *nilpotent* ideals \( I \triangleleft J \) (\( I^{[n]} = 0 \) for some \( n \)), where the Jordan power \( I^{[n]} \) consists of all Jordan products from \( I \) of degree \( \geq n \), counting \( U_x y \) as degree 2 in \( x \); here \( I^{[n]} \subset I^n \) when \( J \subset A \), equivalently no *solvable* ideals (some \( I^{[n]} = 0 \), where \( I^{[0]} = I \) and \( I^{[n+1]} = U_j I^{[n]} \)); here \( I^{(n)} \) remains an ideal in \( J \) if \( I \) is, in contrast to \( I^{[n]} \); when \( J \subset A \) we have \( I^{(n)} \subset J^{3^n} \), equivalently no *trivial* ideals (\( I^{(1)} = U_j I = I^{[3]} = 0 \)). \( J \) is *strongly semiprime* if it has no *trivial elements* \( I \subset J = 0 \); in general this is more restrictive than just being semiprime.) Again there is a unique ideal \( \mathcal{P}(J) \triangleleft J \) minimal among those with semiprime quotient, and it may be recursively constructed as \( \mathcal{P}_\lambda(J) \) as in the associative case via \( \mathcal{P}_{\lambda+1}(J) = \sum \{ I | I \triangleleft J \text{ is nilpotent modulo } \mathcal{P}_\lambda(J) \} \). (We obtain a slightly quicker chain of \( \mathcal{P}_\lambda(J) \) by summing the \( I \) which are solvable.)

We say an associative \( A \) is an *associative envelope* for \( J \subset A \) if \( J \) generates \( A \) as associative algebra.

**Semiprime Envelope Theorem** [3, Lemma 6, p. 93]. If \( J \) is a special Jordan algebra, then

\[
\mathcal{P}(J) = J \cap \mathcal{P}(A)
\]

for any associative envelope \( A \) for \( J \). Thus a special Jordan algebra is semiprime if it has some semiprime associative envelope.

**Proof.** We begin by showing that

\[
(1) \quad \mathcal{P}(A) \cap J \subset \mathcal{P}(J).
\]

This will show that if \( J \) is semiprime then it has a semiprime associative envelope \( \tilde{A} = A/\mathcal{P}(A) \) (\( J \cap \mathcal{P}(A) \subset \mathcal{P}(J) = 0 \) implies \( J = J/J \cap \mathcal{P}(A) = J + \mathcal{P}(A)/\mathcal{P}(A) \subset A/\mathcal{P}(A) \)). In view of the recursive construction of \( \mathcal{P}(A) \), it suffices to establish

\[
(1') \quad \mathcal{P}_\lambda(A) \cap J \subset \mathcal{P}_\lambda(J)
\]

by induction on \( \lambda \). The case \( \lambda = 0 \) is trivial (\( \mathcal{P}_0(A) = 0 \)), as is the case of a limit ordinal \( \lambda \) (\( \mathcal{P}_\lambda(A) = \bigcup_{\mu < \lambda} \mathcal{P}_\mu(A) \) where \( \mathcal{P}_\mu(A) \cap J \subset \mathcal{P}_\mu(J) \) by the induction hypothesis), so we need only prove the assertion \((1')\) for \( \lambda + 1 \) given the assertion for \( \lambda \). Now \( \mathcal{P}_{\lambda+1}(A) \) is the sum of all ideals \( B \triangleleft A \) which are nilpotent modulo \( \mathcal{P}_\lambda(A) \), \( B^n \subset \mathcal{P}_\lambda(A) \) for some \( n = n(B) \). We claim we have an elemental characterization

\[
(2) \quad \mathcal{P}_{\lambda+1}(A) = \{ x \in A | Ax \bar{A} \text{ is nilpotent modulo } \mathcal{P}_\lambda(A) \}.
\]

Certainly \( \mathcal{P}_{\lambda+1}(A) \) contains all such \( x \), and conversely any \( x \in \mathcal{P}_{\lambda+1}(A) \) is such an element: \( x \) has the form \( x = x_1 + \cdots + x_r \) for \( x_k \in B_k \triangleleft A, B^{n_k} \subset \mathcal{P}_\lambda(A) \), so if we set \( n = n(x) = (n_1 - 1) + \cdots +(n_r - 1) + 1 \) then \( (Ax \bar{A})^n = \sum Ax_{i_1} \bar{A}x_{i_2} \cdots \bar{A}x_{i_r} \bar{A} \) where in each summand some \( x_k \) appears at least \( n_k \) times (else each appears at most \( n_k - 1 \) times, and there would be at most \( (n_1 - 1) + \cdots +(n_r - 1) = n - 1 \) total factors \( x_k \), and therefore falls in \( B^{n_k} \subset \mathcal{P}_\lambda(A) \), so \( (Ax \bar{A})^n \subset \mathcal{P}_\lambda(A) \). This establishes \((2)\).
To prove (1') for $\lambda + 1$, if $x \in \mathcal{P}_{\lambda+1}(A) \cap J$ then the Jordan ideal $I(x)^{<J}$ generated by $x$ has $I(x) \subset \hat{A}x\hat{A}$, so by (2) there is an $n$ such that $I(x)^{[n]} \subset (\hat{A}x\hat{A})^n \cap J \subset \mathcal{P}_{\lambda}(A) \cap J \subset \mathcal{P}(J)$ by the induction hypothesis on $\lambda$; by definition of $\mathcal{P}_{\lambda+1}(J)$ we have $I(x) \subset \mathcal{P}_{\lambda+1}(J)$, therefore $x \in \mathcal{P}_{\lambda+1}(J)$. This completes the inductive proof of (1'), hence establishes the inclusion (1). This direction does not use that $A$ is an envelope, only that $A \supseteq J$.

The reverse inclusion

(3) $\mathcal{P}(J) \subset J \cap \mathcal{P}(A)$

is more difficult, at least for quadratic algebras where $\frac{1}{2} \notin \Phi$. It can be reformulated as saying that if $J$ has a semiprime envelope it must itself be semiprime,

(3') $A$ semiprime $\Rightarrow$ $J$ semiprime

(clearly (3) $\Rightarrow$ (3') since semiprimeness means $\mathcal{P} = 0$, and conversely (3') $\Rightarrow$ (3) since $A = A/\mathcal{P}(A)$ is a semiprime envelope for $J = J + \mathcal{P}(A)/\mathcal{P}(A) = J/J \cap \mathcal{P}(A)$, and $J$ semiprime forces $\mathcal{P}(J) \subset J \cap \mathcal{P}(A)$ by minimality of $\mathcal{P}(J)$). Since semiprimeness of $J$ amounts to absence of trivial ideals, (3') is equivalent to

(3'') $A$ semiprime, $I^{[3]} = 0$ for $I^{<J} \Rightarrow I = 0$.

This is the version we will establish. From now on we assume $A$ is a semiprime envelope for $J$ and $I$ is a trivial ideal in $J$, and we will prove that $I = 0$.

We begin by developing some criteria for things to vanish in a semiprime envelope. First we have

**Criterium I.** If $S \subset A$ is a subspace with $JS \subset S\hat{A}$ (equivalently, $J \circ S \subset S\hat{A}$ or $[J,S] \subset S\hat{A}$), then

$$zS = 0 \quad (z \in S\hat{A}) \Rightarrow z = 0,$$

since $JS \subset S\hat{A}$ for the generating set $J$ shows $AS\hat{A} \subset S\hat{A}$ and hence $zAz \subset zAS\hat{A} \subset zS\hat{A} = 0$ forces $z = 0$ by semiprimeness of $A$. When $K^{<J}$ is a Jordan ideal we have $J \circ K \subset K$, so Criterion I for $S = K$ becomes

**Criterion II.** If $K^{<J}$ is a Jordan ideal then

$$zK = 0 \quad (z \in K\hat{A}) \Rightarrow z = 0.$$

When $c$ commutes with $J$ and has square zero, $c^2 = [J,c] = 0$, then $c(\Phi c) = [J,\Phi c] = 0$, so Criterion I for $S = \Phi c$ becomes

**Criterion III.** If $c \in A$ has $c^2 = [c,J] = 0$ then $c = 0$. (Alternately, observe $c$ is nilpotent in the center of $A$ when it commutes with the generators $J$, hence $c = 0$ by semiprimeness.) Combining the last two special cases gives

**Criterion IV.** If $K^{<J}$ is an ideal then

$$U_zK = \{z\hat{J}K\} = 0 \quad (z \in K\hat{A}) \Rightarrow z = 0,$$

since by Criterion II it suffices to show $zK = 0$, i.e. $c = zw = 0$ for all $w \in K$, and this follows from Criterion III since $c^2 = zwzw = 0$ if $U_zK = 0$, and $[c,J] = 0$ if $\{z\hat{J}K\} = 0$ since for all $x \in J$ we have $[c,x] = zwx - xzw = zwx + xzw - x\{z1w\} = \{z,1,w \circ x\} - \{zwx\} - x\{z1w\} \in \hat{J}\{z\hat{J}K\} = 0$. 

License or copyright restrictions may apply to redistribution; see http://www.ams.org/journal-terms-of-use
Criterion I is in turn the special case $K = \hat{J}$ of a more general

**Criteron V.** If $S \subset \hat{AK}$ is a subspace with $JSK \subset \hat{S}$ for some ideal $K < J$, then

$$zS = 0 \quad (z \in \hat{S}) \quad \Rightarrow \quad z = 0$$

since then $z \in S' = \{ w \in \hat{S} | wS = 0 \}$, where $S'JS = 0$ by Criterion II ($S'JS \subset \hat{AK}$ has $(S'JS)K = S'(JSK) \subset S'(\hat{S})\hat{A} = (S'S)\hat{A} = 0$ by hypothesis on $S$ and definition of $S'$), thus $S'J \subset S'$ shows $S'\hat{A} \subset S'$, and therefore $zAz \subset (S')\hat{A}(\hat{S}) \subset S'S\hat{A} = 0$ forces $z = 0$ by semiprimeness of $A$.

Using these criteria we quickly see our trivial ideal $I$ vanishes when $A$ has no 2-torsion. Denote by $I^{(2)}$ the span of all Jordan squares $z^2$ for $z \in I$, thus including all $z \circ w$ (*not* the associative square $I^2 = II$ spanned by all associative products $zw$).

Then $S = I^{(2)}$ and $K = I$ satisfy the hypotheses of Criterion V ($IJ^{(2)}I \subset I^{(2)}\hat{A}$ when $I^{[3]} = 0$ since for $x \in J$, $z, w \in I$ we have $xz^2w = \{ x \circ z, z, w \} - U_zx \circ w - \{ wzz \} x + z^2wx \in I^{[3]} - I \circ I - I^{[3]}J + I^{(2)}A \subset I^{(2)}\hat{A}$), and $SS = 0$ (by $z^2w^2 = \{ zzw \} w - w^2z^2w \in I^{[3]}\hat{A} = 0$), so by Criterion V we have $S = 0$:

$$I^{(2)} = 0.$$  

Applying Criterion IV to $K = I$ and $z \in 2I$ (note $U_zK \subset I^{[3]} = 0$ and $\{ zJk \} \subset 2U_{I,J}\hat{A} \subset I \circ (I \circ \hat{J}) - (I \circ I) \circ \hat{J} = 0$ since $I \circ I = 0$ by (4)), we see $z = 0$:

$$2I = 0.$$  

For linear Jordan algebras where $\frac{1}{2} \in \Phi$, this yields the desired condition $I = 0$. For the general quadratic case we must argue at greater length. Since the product $\hat{U}_KL$ of two ideals is again an ideal, we get a smaller ideal

$I' = \hat{U}_J \subset J$, $I' \subset I$.

This new ideal satisfies

$$I' \circ \hat{J}^{(2)} = 0$$

since for $z \in I$, $x, y \in \hat{J}$ we have $U_{y, z^2}^2 = \{ x \circ z, z, w \} - U_{z^2 \circ y} \in I \circ I - (\{ z \circ x \} - \{ z \circ y \} \circ y \subset I \circ I - \{ J^{(2)} - \hat{U}_j I^{(2)} - I \circ I \} \circ \hat{J} = 0$ by (4). In view of (5) this shows $I'$ commutes with $J^{(2)}$; we claim it actually commutes with $J$,

$$I', J \circ J = 0,$$

i.e. $[x, I'] = 0$ for each $x$ in $J$. Now $S = [x, I'] = x \circ I'$ (via (5)) satisfies the hypotheses of Criterion I:

$$J \circ S = J \circ (x \circ I') = 2U_{x, y} I' - x \circ (J \circ I') + (J \circ x) \circ I' \subset 0 - x \circ I' + 0 = S$$

by (5), $I' \subset J$, and (6). Furthermore, $SS = 0$ since for $z', w' \in I'$ we have

$$(x \circ z')(x \circ w') = xz'(x \circ w') + z'x(x \circ w')$$

$$= -(x \circ w')z' + z'x^2w' + z'xw'x$$

$(z' \in I$ anticommutes with $x \circ w' \in I$ by (4))

$$= -x^2w'z' - xw'z'x + x^2z'w' - xz'w' + 2z'xw'x$$

$(z' \in I$ anticommutes with $x^2$ by (6))

$$= -x^2(w' \circ z') - (xw'x) \circ z' + 2z'xw'$$

$$= 0 \quad (by \ (4), (5)).
Thus by Criterion I we have $S = 0$, $[x, I'] = 0$ for each $x$, and (7) holds. But then we can apply Criterion III to any $c \in I'$ (note $c^2 \in I^{(2)} = 0$ by (4)) to see $c = 0$, thus $I'$ vanishes:

$$I' = 0.$$  \hspace{1cm} (8)

In particular, $\{ I \hat{J} I \} \subset I' = 0$, so by Criterion IV for $K = I$ we see any $z \in I$ vanishes,

$$I = 0$$  \hspace{1cm} (9)

as desired. This completes the proof of (3'') and the Theorem.
