UNITAL MULTIPLICATIONS ON A HILBERT SPACE

JOHN FROELICH

(Communicated by Palle E. T. Jorgensen)

Abstract. We provide a new proof of two theorems of Ingelstam that identify the Hilbert spaces with a unital multiplication satisfying \(\|xy\| \leq \|x\| \|y\|\) and \(\|1\| = 1\).

Ingelstam [3, Corollary 2], as a consequence of his analysis of the vertex property for Banach algebras with identity, proved that any complex Hilbert space admitting a unital multiplication satisfying

\[\|xy\| \leq \|x\| \|y\|, \quad \|1\| = 1\]

must be the complex numbers. It was later conjectured by Kaplansky [4] and proved by Ingelstam [4, Theorem 2] that any real Hilbert space admitting a unital multiplication with the above properties must be the real, complex, or quaternion numbers.

The above results are relevant to the theory of strictly cyclic operator algebras [5, 8], and our recent interest in these algebras led us to reconsider the proofs. A unital operator algebra \(\mathcal{A}\) on a Hilbert space \(H\) is called strictly cyclic if there is a vector \(h \in H\) such that the linear manifold \(\mathcal{A}h = \{Ah : A \in \mathcal{A}\} = H\). The algebra is called separated if in addition \(Ah = 0\) implies that \(A = 0\). If \(\mathcal{A}\) is a separated strictly cyclic algebra with strictly cyclic and separating vector \(e\) then the map \(A \to Ae\) gives a Banach space isomorphism between the operator algebra \(\mathcal{A}\) and the Hilbert space \(H\). Thus the operator norm on \(\mathcal{A}\) is equivalent to an inner product norm \(\|\|\). Therefore we may choose \(\|\|\) such that

\[\|AB\| \leq K\|A\|\|B\|, \quad \|1\| = 1\]

for any \(A, B \in \mathcal{A}\), where \(K \geq 1\). Conversely, given a Hilbert space \(H\) with unital multiplication satisfying the above properties, the left regular representation

\[\mathcal{A} = \{L_h : h \in H\}, \quad L_h(k) = h \cdot k\]

is a separated strictly cyclic operator algebra with cyclic vector 1 and the operator norm on \(\mathcal{A}\) is equivalent to the Hilbert space norm.

Thus separated strictly cyclic operator algebras and Hilbert spaces with continuous unital multiplication are equivalent notions and Ingelstam’s results may
be interpreted as saying that the operator norm equals the Hilbert space norm
only in certain special cases.

In this paper we provide a unified approach to Ingelstam’s theorems that
relies only on a few elementary ideas from the theory of Banach algebras and
Hilbert space geometry.

**Theorem 1.** Let $H$ be a real Hilbert space with a unital multiplication satisfying

$$
\|xy\| \leq \|x\| \|y\|,
$$

$\|1\| = 1$.

Then $H$ is the real, complex, or quaternion numbers.

**Proof.** We will show that $H$ is a division ring. If not, then there is a nonzero
$a \in H$ that is not invertible. Consider the closed subalgebra $A$ generated by
$a, 1$. There is a maximal ideal $M \subset A$ containing $a$. Then $A/M$ is a field
isomorphic to $R$ by the map $[\lambda \cdot 1] \to \lambda$, and we have that $q: A \to A/M \approx R$
is a multiplicative linear functional with $q(1) = 1$, $\ker q = M$, and $\|q\| = 1$
[7, Theorem 10.7]. By the Riesz-representation theorem there is a $y \in A$ such that

$$q(x) = (x, y) \text{ for all } x \in A.$$

Since $\|q\| = 1$, it follows that $\|y\| = 1$ and $q(1) = 1 = (1, y)$ implies that $y = 1$
by the equality condition of the Cauchy-Schwarz inequality. It follows from
$\ker q = M$ that $1$ is orthogonal to $M$. Therefore $A = R \oplus M$ isometrically.

Let $m \in M$ and consider

$$
\|(1 + m)^2\|^2 \leq (1 + \|m\|^2)(1 + \|m\|^2).
$$

This yields

$$2\|m\|^2 \leq \|m\|^4 - \|m^2\|^2 - 4(m, m^2).$$

Replacing $m$ by $\varepsilon \cdot m$, dividing by $\varepsilon^2$, and letting $\varepsilon \to 0$, we obtain that
$\|m\| = 0$ so $M = \{0\}$. This is a contradiction. It follows that $H$ is a normed
division ring over $R$ and so $H$ is the real, complex, or quaternion numbers [6,
Theorem 1.7.6].

The same argument also produces

**Theorem 2.** Let $H$ be a complex Hilbert space with a unital multiplication sat-
ifying

$$
\|xy\| \leq \|x\| \|y\|,
$$

$\|1\| = 1$.

Then $H = C$.

**Added in proof**

After the paper was submitted we discovered that M. F. Smiley [9] has also
obtained a simplification of Ingelstam’s theorems different from ours.
