MARKOV'S EXponent of compact sets in \( \mathbb{C}^n \)

M. Baran and W. Pleśniak

(Communicated by Eric Bedford)

Abstract. We introduce the notion of Markov's exponent of a compact set in \( \mathbb{C}^n \) and show that it is invariant under regular analytic maps.

1. Markov's Inequality

Given a compact subset \( E \) of the space \( \mathbb{C}^n \) and a number \( r \geq 1 \), consider the following two conditions.

\[ M(r) \] There exists a constant \( M_1 > 0 \) such that for each \( p \in \mathcal{P}_k, k = 1, 2, \ldots \),
\[
\| \text{grad } p \|_E \leq M_1 k^r \| p \|_E.
\]

\[ P(r) \] There exist two positive constants \( M_2 \) and \( C_2 \) such that for each \( p \in \mathcal{P}_k, k = 1, 2, \ldots \),
\[
|p(x)| \leq M_2 \| p \|_E, \quad \text{as } \text{dist}(x, E) \leq \frac{C_2}{k^r}.
\]

Here \( \mathcal{P}_k \) denotes the space of all polynomials of degree at most \( k \). The condition \( M(r) \) is a multidimensional version of the well-known inequality, proved by A.A. Markov in 1889 in the case where \( E = [-1, 1] \). For the proof of this famous result and its one-dimensional generalizations we refer the reader to [RS]. Some criteria for subsets of \( \mathbb{C}^n \) satisfying \( M(r) \) have been proved in [PP1], [B1] and [B2]. In particular, it is known that every fat subanalytic set and, more generally, every uniformly polynomially cuspidal set satisfies \( M(r) \), for some \( r \geq 1 \). Markov's inequality has been applied in problems connected with approximation and extension of \( \mathcal{C}^\infty \) functions (see [PP2] and [P13]).

Given a compact set \( E \) in \( \mathbb{C}^n \), an important point is to determine the minimal constant \( r \) in \( M(r) \). This permits, in particular, the minimization of the loss of regularity in problems connected with the linear extension of classes of \( \mathcal{C}^\infty \) functions with restricted growth of derivatives (see [PS] and [P14]). In the next section we call such an \( r \) Markov's exponent of \( E \) and show that it is invariant under regular holomorphic maps. We close this section by proving the following observation.

Proposition 1.1. For each $r \geq 1$, the properties $M(r)$ and $P(r)$ of the set $E$ are equivalent.

Proof. Assume $M(r)$. Fix $a \in E$, $v \in \mathbb{C}^n$ with $\|v\| = 1$, and $p \in \mathcal{R}_k$, and define $q(t) = p(a + tv)$. Observe that $q^{(j)}(t) = D_v^j p(a + tv)$. In particular, we have $q^{(j)}(0) = D_v^j p(a)$. Hence, if $t \in \mathbb{C}$ and $|t| \leq C_2/k'$, we can write

$$|q(t)| = \left| \sum_{j=0}^{k} \frac{1}{j!} t^j q^{(j)}(0) \right| \leq \sum_{j=0}^{k} \frac{1}{j!} |t|^j |D_v^j p(a)| \leq \sum_{j=0}^{k} \frac{1}{j!} M^j |t|^j \|p\| E \leq M_2 \|p\| E.$$

The inverse implication follows easily from Cauchy’s integral formula. The proof is completed.

2. Markov’s exponent

Given a compact subset $E$ of the space $\mathbb{C}^n$, we define

$$\mu(E) = \inf \{ r : E \text{ satisfies } M(r) \}$$

and call this number Markov’s exponent of $E$. If $E$ is a continuum in $\mathbb{C}$ containing at least two different points, then by [Po], $1 \leq \mu(E) \leq 2$. For any compact subset $E$ of $\mathbb{R}^n$, we have $\mu(E) \geq 2$. If $E$ is a fat convex subset of $\mathbb{R}^n$, then $\mu(E) = 2$. If $E = \{(x, y) \in \mathbb{R}^2 : 0 \leq x \leq 1, 0 \leq y \leq x^p\}$, for $p \geq 1$, then by [G] $\mu(E) = 2p$. In a more general case, if $E$ is an $m-UPC$ subset of $\mathbb{R}^n$ ($m \geq 1$) (see [PP1]), then by [B2] $\mu(E) \leq 2m$. If $E = \{(x, y) \in \mathbb{R}^n : 0 < x \leq 1, 0 < y \leq e^{-1/x}\} \cup \{(0, 0)\}$, then by [Z] $\mu(E) = \infty$. The following example is a slight generalization of the above-mentioned results of Goetgheluck and Zerner.

Example 2.1. Let $\phi$ be a convex, increasing $C^1$ function defined on $[0, 1]$ such that $\phi(0) = \phi'(0) = 0$, $\phi(1) = 1$. Define

$$E = E_\phi = \{(x, y) \in \mathbb{R}^2 : |x| \leq 1, |y| \leq \phi(1 - |x|)\}.$$

Then, for any polynomial $p \in \mathcal{R}_k$, $k = 0, 1, \ldots$, we have

$$(2.1.1) \quad \|\frac{\partial p}{\partial x}\| E \leq \phi'(1)k^2\|p\| E.$$

Moreover, let

$$\alpha = \liminf_{t \to 0^+} \frac{\log \phi(t)}{\log t}, \quad \beta = \limsup_{t \to 0^+} \frac{\log \phi(t)}{\log t}.$$

Then, if $\beta < \infty$, for any $\epsilon > 0$ we have

$$\|\frac{\partial p}{\partial y}\| E \leq \text{const.} k^{2(\beta + \epsilon)}\|p\| E,$$

whence $\mu(E) \leq 2\beta$ ($\mu(E) = 2$, if $\beta = 1$). If $\alpha = \infty$, then

$$(2.1.3) \quad \mu(E) = \infty.$$

If $\phi$ satisfies Orlicz’s $\Delta_2$ condition at 0 (i.e., $\phi(2u) \leq \text{const.} \phi(u)$), then $\beta < \infty$ and $\phi$ does not satisfy this condition in case $\alpha = \infty$.

Proof. Let $e_1 = (1, 0)$ and $e_2 = (0, 1)$, and let

$$\rho_i(x, y) = \text{dist}_{e_i}((x, y), \mathbb{R}^2 \setminus E).$$
be the distance of \((x, y) \in E\) from the boundary of \(E\) in direction of the vector \(e_i\), for \(i = 1, 2\). Then one can easily check that

\[
\rho_1(t(x, y)) \geq \frac{1}{\phi'(1)}(1 - |t|)
\]

and

\[
\rho_2(t(x, y)) \geq \phi(1 - |t|)
\]

for \(t \in [-1, 1]\) and \((x, y) \in \partial E\). Now, by (2.1.4), applying a version of Markov’s inequality for star-shaped sets (see [B2, Thm. 3.6]) gives (2.1.1) (cf. [B2]). If \(\beta < \infty\), then, for each \(\epsilon > 0\), \(\phi(t) \geq \text{const.} t^{\beta + \epsilon}\) for \(t \in [0, 1]\). Hence by (2.1.5) and by [B2, Thm. 3.6] we get (2.1.2). Following an idea of Zerner [Z], suppose now that \(\alpha = \infty\). Then, for each \(r > 0\), we have \(\frac{\log \phi(t)}{\log t} \geq r\), if \(0 < t \leq \delta = \delta(r)\); whence \(\phi(t) \leq M t^r\) for \(0 \leq t \leq 1\), where \(M > 0\) is a constant depending on \(r\). Now, if we take \(p_k(x, y) = x^k y\), then

\[
\|\frac{\partial p_k}{\partial y}\|_E = 1
\]

and

\[
\|p_k\|_E = \sup_{|x| \leq 1} |x|^k \phi(1 - |x|) \leq M \sup_{0 \leq t \leq 1} t^k (1 - t)^r = M \left(\frac{k}{k + r}\right)^k t^r
\]

\[
\leq M r^{-r - 1} \frac{1}{(k + 1)^r} = M_1(r) \frac{1}{(k + 1)^r}.
\]

Consequently,

\[
\|\frac{\partial p_k}{\partial y}\|_E \geq M_2(r)(k + 1)^r\|p_k\|_E
\]

which shows that \(E\) cannot have Markov’s property. Let

\[
a_\phi^0 = \liminf_{t \to 0^+} \frac{t \phi'(t)}{\phi(t)}, \quad b_\phi^0 = \limsup_{t \to 0^+} \frac{t \phi'(t)}{\phi(t)}
\]

be the lower and upper Simonenko indices at \(0\), respectively (see [M]). By Cauchy’s mean value theorem

\[
a_\phi^0 \leq \alpha \leq \beta \leq b_\phi^0,
\]

and the relation between \(\alpha\), \(\beta\) and the \(\Delta_2\) condition follows from [M, Thm. 3.2(b)].

Consider e.g. \(\phi(t) = t^p\), \(p > 1\). Then \(\phi'(1) = p\), \(\alpha = \beta = p\). If \(\phi(t) = e^{2(1-t^{-1})}\), then \(\phi'(1) = 2\) and \(\alpha = \beta = \infty\). If \(\phi(t) = t(1 - \log t)^{-1}\), then \(\phi'(1) = 2\) and \(\alpha = \beta = 1\).

To prove the invariance of Markov’s exponent under analytic mappings we need the following.

**Lemma 2.2.** Let \(E\) be a polynomially convex, compact subset of \(\mathbb{C}^n\) satisfying \(M(r)\). Let \(f\) be a holomorphic mapping defined in a neighbourhood \(U\) of \(E\), with values in \(\mathbb{C}^m\), such that \(f(E)\) is not pluripolar. Then there exist positive constants \(M_2\) and \(C_3\) such that for each polynomial \(p \in \mathcal{P}_k(\mathbb{C}^m)\) and \(k = 1, 2, \ldots\), we have

\[
|(p \circ f)(x)| \leq M_2\|p \circ f\|_E \quad \text{as \text{dist}(x, E) \leq \frac{C_3}{k^r}}.
\]
Proof. Without loss of generality we may assume that \( f \) is bounded on \( U \). Since \( E \) is polynomially convex, one can find a compact polynomial polyhedron \( P \) such that \( E \subset \text{int} P \subset P \subset U \). By a uniform version of the Bernstein-Walsh-Siciak theorem (see [Pll]), there exist constants \( A > 0 \) and \( a \in (0, 1) \) such that for any polynomial \( p \in \bigcup_{k=0}^{\infty} \mathcal{P}_k(\mathbb{C}^m) \), we have

\[
\text{dist}_p(p \circ f, \mathcal{P}_i(\mathbb{C}^n)) \leq Aa^l \|p \circ f\|_U.
\]

Since \( f(E) \) is not pluripolar, we have \( \|p \circ f\|_U = \|p\|_{f(U)} \leq \|p\|_{f(E)}B_k \), where \( B = \sup\{\Phi_{f(E)}(w) : w \in f(U)\} < \infty \) and where \( \Phi_{f(E)} \) denotes Siciak's extremal function associated with \( f(E) \) ([S1],[S2]). Choose \( k_0 \) such that \( E_k(C_2, r) := \{x \in \mathbb{C}^n : \text{dist}(x, E) < C_2/k^r\} \subset P \) for \( k \geq k_0 \). Let \( s \in \mathbb{N} \) be so large that \( a^rB \leq 1 \), and let \( q_k \) be a best approximation polynomial to \( p \circ f \) of degree \( l = sk \). Then by (2.2.1), since \( E \) satisfies \( P(r) \), we can write

\[
|p(x)| \leq Aa^sk^k \|p \circ f\|_E + |q(x)| \leq A\|p \circ f\|_E + M_2\|q\|_E \leq (A + 2M_2)\|p \circ f\|_E
\]
as \( \text{dist}(x, E) \leq C_2/(sk^r) \), which gives the lemma with \( C_3 = C_2/s^r \) and \( M_3 = A + 2M_2 \).

Corollary 2.3. Under the assumptions of Lemma 2.2, there exists a positive constant \( M'_3 \) such that for each \( v \in \mathbb{C}^m \) with \( \|v\| = 1 \), we have

\[
\|D_v(p \circ f)\|_E \leq M'_3k^r\|p \circ f\|_E.
\]

Proof. Fix \( a \in E \) and \( v \in \mathbb{C}^m \) with \( \|v\| = 1 \), and define \( g(t) := (p \circ f)(a + tv) \). By Cauchy's integral formula, for \( \delta = C_3/k^r \), we get

\[
|D_v(p \circ f)(a)| = |g'(0)| \leq \sup\{|g(\zeta) : |\zeta| = \delta\}/\delta \leq (M_2/C_3)k^r\|p \circ f\|_E.
\]

Remark 2.4. The assumption that \( f(E) \) is not pluripolar yields immediately the restrictions that \( m \leq n \) and \( f \) is non-degenerate at least in one of the connected components of \( U \), say \( V \), that meets the set \( E \), which means that \( \sup_{x \in V} \text{rank}_x f = m \). If we knew that the Markov property of \( E \) implies that \( E \) is not pluripolar, we could replace the above assumption on \( f(E) \) by the requirement that \( f \) is non-degenerate on at least one of the connected components of \( U \) that meet \( E \) at a non-pluripolar set. This, however, still seems to be unknown except when \( E \) is a Cantor type subset of \( \mathbb{R} \) (see [P12],[BC]).

Lemma 2.2 together with Proposition 1.1 permits us to give a "sharp" version of Proposition 4.1 in [P13] by showing that Markov's exponent of a compact set is invariant under holomorphic injections. More precisely, we have the following

Theorem 2.5. Under the assumptions of Lemma 2.2, suppose that \( m = n \) and \( \det d_x f \neq 0 \) for each \( x \in E \). Then \( f(E) \in M(r) \).

Proof. Choose \( c > 0 \) so that \( |J_{c}f(x)|^2 \geq c \). By the assumptions and the implicit function theorem there exist positive constants \( L \) and \( L_1 \) such that for each \( x \in E \) and each \( \delta \in (0, c] \), \( f(B(x, L\delta)) \subseteq B(f(x), L_1\delta) \) (see [T, Chap. I, Prop. 5.1]). Choose \( k_0 \in \mathbb{N} \) so that \( C_3/Lk^r \leq c \) for \( k \geq k_0 \). Then by Lemma 2.2, for a fixed \( b \in f(E) \) and \( a \in f^{-1}\{b\} \), we get

\[
|p(w)| \leq M_2\|p\|_{f(E)} \text{ as } |w - b| \leq L_1C_3/Lk^r,
\]
for any polynomial \( p \in \mathcal{P}_k(\mathbb{C}^m) \) and \( k \geq k_0 \). Since \( f(E) \) is not pluripolar, the last inequality holds for any \( k \in \mathbb{N} \) after a suitable change of the constant \( M_2 \). In view of Proposition 1.1, the proof of the theorem is complete.

Remark 2.6. Note that for any compact subset \( E \) of \( \mathbb{C}^n \), \( E \) satisfies \( M(r) \) iff \( \hat{E} \in M(r) \) where \( \hat{E} \) denotes the polynomial hull of \( E \). However, the assumption that \( E = \hat{E} \) cannot be removed. To see why, take \( E \) to be the set \( \{ z \in \mathbb{C} : |z| = 1 \} \cup \{ 0 \} \) and \( f(z) = 1/(z - 1/2) \). Choose a polynomial \( p \) such that \( \| p \|_{L^1(\mathbb{R})} \leq 1 \) and \( |p(2) - 0| \geq 2 \). Then, if \( f(E) \) satisfied \( \mathcal{M}(r) \) for a certain \( r > 0 \), we would have, for \( q_n(z) = (z + 2)p^n(z), 2^n \leq |q_n(-2)| \leq M(nd + 1)^r \| q \|_{L^1(\mathbb{R})} \leq 4M(nd + 1)^r \), for \( n = 1, 2, \ldots \) with a positive constant \( M \) independent of \( n \) and where \( d \) denotes the degree of \( p \), a contradiction.

Suppose now \( E \) is a compact subset of the space \( \mathbb{R}^n \). (Here we assume that \( \mathbb{R}^n \) is a subset of \( \mathbb{C}^n \) such that \( \mathbb{C}^n = \mathbb{R}^n + i\mathbb{R}^n \).) Suppose moreover \( E \) is a UPC set (cf. [PP1]). This means that there exist positive constants \( M \) and \( m \), a positive integer \( d \) and a mapping \( h : E \times [0, 1] \to E \) such that for each \( x \in E \), \( h(x, \cdot) \) is a polynomial of degree at most \( d \), \( h(x, 1) = x \) and \( \text{dist}(h(x, t), \mathbb{R}^n \setminus E) \geq M(1 - t)^m \) for all \( (x, t) \) in \( E \times [0, 1] \). It was shown in [PP2] that if \( f \) is a \( \mathcal{C}^\infty \) mapping defined in \( \mathbb{R}^n \) with \( J_Rf(x) \neq 0 \) on \( E \), then \( f(E) \) also is a UPC subset of \( \mathbb{R}^n \), whence a Markov set. If we drop the assumption that \( \det d_xf \neq 0 \) everywhere on \( E \), the above theorem fails to hold, which is seen by the following

Counter-example 2.7. Take \( E \) to be the set \( \{(x, y) \in \mathbb{R}^2 : 0 \leq x \leq 1, 0 \leq y \leq x\} \). Then \( E \) satisfies \( M(2) \), since it is convex. Consider now the map \( f(x, y) = (x, y\phi(x)) \) for \( (x, y) \in \mathbb{R}^2 \), where
\[
\phi(x) = \begin{cases} 
eq^{-1/x} & \text{if } x > 0, \\
0 & \text{otherwise.} 
\end{cases}
\]
Then \( f \) is a \( \mathcal{C}^\infty \) mapping on \( \mathbb{R}^2 \) with \( \det d_{(x,y)}f \neq 0 \) on \( E \setminus \{(0, 0)\} \). Nevertheless, the set \( f(E) = \{(u, v) \in \mathbb{R}^2 : 0 \leq u \leq 1, 0 \leq v \leq u\phi(u)\} \) is known to not preserve Markov’s inequality for any order \( r > 0 \).

The situation is much better when \( f \) is a polynomial. We have

Theorem 2.8. Let \( E \) be a compact subset of \( \mathbb{R}^n \) that is UPC with parameters \( M > 0, m \geq 1 \) and \( d \in \mathbb{N} \). Let \( f : \mathbb{R}^n \to \mathbb{R}^n \) be a polynomial map of degree \( l \) with \( \det d_xf \neq 0 \) on \( \text{int} \, E \). Then there exist constants \( M_0 > 0 \) and \( m_0 \geq 1 \) such that
\[
\|(d_xf)^{-1}\| \leq M_0(\text{dist}(x, \partial E))^{-m_0}
\]
and for any polynomial \( p \in \mathcal{P}_k \), \( k = 0, 1, \ldots, \)
\[
\|\text{grad} \, p\|_{L^1(\mathbb{R})} \leq Ck^{2m(m_0+1)}\|p\|_{L^1(\mathbb{R})}
\]
with \( C = 2M_0M^{-(m_0+1)}(2d)^{2m(m_0+1)} \).

Proof. If \( x \in \text{int} \, E \), by Cramer’s Rule and Hadamard’s inequality we can write
\[
\|(d_xf)^{-1}\| \leq \text{const.} \, |\det d_xf|^{-1}.
\]
Let \( X = \{ x \in \mathbb{R}^n : \det d_xf = 0 \} \). By Lojasiewicz’s inequality, there exist constants \( A > 0 \) and \( \alpha \geq 1 \) such that for each \( x \in \text{int} \, E \) we have
\[
|\det d_xf| \geq A[\text{dist}(x, X)]^\alpha \geq A[\text{dist}(x, \partial E)]^\alpha.
\]
This completes the proof of the first part of the theorem. To prove (2.8.2) fix a polynomial $p \in \mathcal{R}_k$ and choose again a point $x \in \text{int } E$. By [B2, Corollary 3.5] $E$ satisfies $M(2m)$ with the constant $M_1 = \sqrt{2}(2d)^{2m}$, whence by (2.8.1) and Corollary 2.3 we can write

$$\| \text{grad } p(f(x)) \| \leq \|(d_x f)^{-1}\| \| \text{grad } (p \circ f)(x)\| \leq M_0 \|\text{dist}(x, \partial E)\|^{-m_0} \sqrt{2M^{-1}(2dk)^{2m}}\|p\|f(E).$$

By the assumptions, $E$ admits a parametrization $h : E \times [0, 1) \ni (x, t) \rightarrow h(x, t) \in \text{int } E$ such that for each $x$, $h(x, 1) = x$, $h(x, \cdot)$ is a polynomial of degree at most $d$ and $\text{dist}(h(x, t), \partial E) \geq M(1 - t)^m$. Hence we obtain, for any $v \in \mathbb{R}^n$ with $\|v\| = 1$,

$$\|D_v p(f(h(x, t^2)))\| \leq LM^{-m_0}(1 - t^2)^{-m_0},$$

with $L = M_0 \sqrt{2M^{-1}(2dk)^{2m}}\|p\|f(E)$. By a generalization of Schur's theorem (see [B2, Lemma 2.4]), this implies that

$$\|D_v p(f(h(x, t^2)))\| \leq LM^{-m_0}(2dk)^{2m_0}$$

for $t \in [-1, 1]$, whence

$$\| \text{grad } p(f(h(x, t^2))\| \leq \sqrt{2LM^{-m_0}(2dk)^{2m_0}}$$

for $t \in [-1, 1]$. Hence by setting $t^2 = 1$ we get the assertion (2.8.2) of the theorem.

The proof of Theorem 2.8 yields the estimate

$$\mu(f(E)) \leq \mu(E) + 2mm_0,$$

which is sharp in the following sense.

**Example 2.9.** Take $E$ to be the set $\{x = (x_1, x_2) \in \mathbb{R}^2 : x_1, x_2 \geq 0, x_1 + x_2 \leq 1\}$. Since $E$ is convex, it satisfies $M(r)$ with $r = 2$. Let $f(x_1, x_2) = (x_1^2, x_2^2)$, $p \in \mathbb{N}$, $p \geq 2$. Then we have, for $x \in \text{int } E$,

$$\|\text{(d}_x \text{f)}^{-1}\| \leq \frac{1}{2}(\min\{x_1, x_2\})^{-(p-1)} \leq \frac{1}{2}(\text{dist}(x, \partial E))^{-(p-1)}.$$

Thus, we have $m = 1$ and $m_0 = p - 1$, and by Theorem 2.8, $\mu(f(E)) \leq 2p$. On the other hand, since $f(E) = \{x \in \mathbb{R}^2 : x_1, x_2 \geq 0, x_1 + \sqrt{x_2} \leq 1\}$, by [G], $\mu(f(E)) = 2p$.
