

## A VERSION OF ZABRODSKY'S LEMMA

JIN-YEN TAI

(Communicated by Thomas Goodwillie)

ABSTRACT. Zabrodsky's Lemma says: Suppose given a fibrant space  $Y$  and a homotopy fiber sequence  $F \rightarrow E \rightarrow X$  with  $X$  connected. If the map  $Y = \text{map}(*, Y) \rightarrow \text{map}(F, Y)$  which is induced by  $F \rightarrow *$  is a weak equivalence, then  $\text{map}(X, Y) \rightarrow \text{map}(E, Y)$  is a weak equivalence. This has been generalized by Bousfield. We improve on Bousfield's generalization and give some applications.

The lemma we refer to here is the following: Suppose given a fibrant space  $Y$  and a homotopy fiber sequence  $F \rightarrow E \rightarrow X$  with  $X$  connected. If the map  $Y = \text{map}(*, Y) \rightarrow \text{map}(F, Y)$  which is induced by  $F \rightarrow *$  is a weak equivalence, then  $\text{map}(X, Y) \rightarrow \text{map}(E, Y)$  is a weak equivalence. This result has been generalized by Bousfield in [B, Theorem 4.6]. Our statement is almost the same as [B, Theorem 4.6]. The only difference is that we assume in Theorem 1.1 that  $Y = \text{map}(*, Y) \rightarrow \text{map}(F_k, Y)$  is a weak equivalence while Bousfield assume that  $\text{map}(\Omega k, Y)$  is a weak equivalence, where  $F_k$  is the homotopy fiber of the map  $k$ . Our assumption is indeed weaker. Our interest in Theorem 1.1 lies in the fact that it is a basic tool in comparing  $f$ -localization functors, and we will give some simple applications in this direction. The technique we use in the proof of Theorem 1.1 has been developed by Chachólski and Dror Farjoun.

### 0. NOTATIONS AND PRELIMINARIES

Let  $\Delta$  denote the simplicial category in which the objects are the ordered sets  $[n] = \{0, 1, \dots, n\}$  and morphisms are nondecreasing maps of sets. A simplicial set (or space) is a contravariant functor  $K$  from  $\Delta$  to the category of sets. As usual we write  $K_n$  for  $K([n])$ , the  $n$ -simplices. Let  $S.sets$  denote the category of simplicial sets (or spaces). The standard  $n$ -simplex  $\Delta[n]$  is the simplicial set with  $k$ -simplices  $\text{Hom}_\Delta([k], [n])$ . There is a distinguished  $n$ -dimensional simplex  $\tau \in \Delta[n]$  which comes from the identity map  $[n] \rightarrow [n]$ . And  $\dot{\Delta}[n]$  denotes the 'boundary' simplex of  $\Delta[n]$ .

For each space  $K$ , there is a canonical way to associate a category to  $K$ , called the transport category of  $K$  or the Grothendieck construction of  $K$ . The objects of this category are pairs  $([n], \sigma)$ , where  $[n]$  is an object of  $\Delta^{op}$  and  $\sigma \in K_n$ . A morphism  $([n], \sigma) \rightarrow ([m], \tau)$  of this category consists of a map  $\phi: [n] \rightarrow [m]$  in  $\Delta^{op}$  such that  $K(\phi)(\sigma) = \tau$ . We will use the same symbol  $K$  to denote both the space  $K$

and its associated category. A *diagram with shape*  $K$  is a functor  $F: K \rightarrow S.sets$ . The homotopy colimit is the following functor:

$$\int_K : \{\text{diagrams over } K\} \rightarrow S.sets,$$

$$\int_K F = (\prod_{\sigma \in K} \Delta[\dim \sigma] \times F(\sigma)) / \sim,$$

where  $\sim$  is an equivalence relation generated by  $(\Delta[\phi](t), x) \sim (t, F(\phi)(x))$  for  $\phi \in \text{Hom}_\Delta([n], [m])$ ,  $\tau \in K_m$ ,  $x \in F(\tau)$  and  $t \in \Delta[n]$ .

A diagram  $F$  is called *bounded* if for every degeneracy morphism  $s_i: \sigma \rightarrow s_i\sigma$ ,  $F(\sigma) = F(s_i\sigma)$  and  $F(s_i) = id_{F(\sigma)}$ . By [C1, 3.12], we know that every map  $f: X \rightarrow Y$  is weakly equivalent to a map  $\int_K F \rightarrow K$  for some bounded diagram  $F: K \rightarrow S.sets$  such that  $F(\sigma)$  is weakly equivalent to the homotopy fiber of  $f$  for each simplex  $\sigma \in K$ . Moreover, for a bounded diagram  $F: K = L \cup_{\Delta[n]} \Delta[n] \rightarrow S.sets$ , by [C1, 3.13],  $\int_K F$  is the homotopy push-out of the diagram

$$\int_L F \longleftarrow \dot{\Delta}[n] \times F(\tau) \longrightarrow \Delta[n] \times F(\tau),$$

where  $\tau$  is the distinguished  $n$ -simplex in  $\Delta[n]$ .

For any map  $f$ , the homotopy fiber and homotopy cofiber of  $f$  are denoted by  $F_f$  and  $C_f$  respectively.

1. ZABRODSKY'S LEMMA

We are going to prove the following version of Zabrodsky's Lemma (cf. [B, Theorem 4.6]). The technique we use here has been developed by Chachólski and Dror Farjoun.

**Theorem 1.1.** *Let*

$$\begin{array}{ccccc} F & \longrightarrow & E & \longrightarrow & X \\ g \downarrow & & h \downarrow & & k \downarrow \\ F' & \longrightarrow & E' & \longrightarrow & X' \end{array}$$

*be a map of homotopy fiber sequences with  $X$  and  $X'$  connected, and let  $F_k$  be the homotopy fiber of  $k$ . For any fibrant space  $Y$ , if the maps  $\text{map}(g, Y)$  and  $Y = \text{map}(*, Y) \rightarrow \text{map}(F_k, Y)$  which is induced by  $F_k \rightarrow *$  are weak equivalences, then  $\text{map}(h, Y)$  is a weak equivalence. If  $Y$  is pointed and connected, we can use  $\text{map}_*(-, -)$  instead of  $\text{map}(-, -)$ . (Of course, the assumption on  $F_k$  becomes  $\text{map}_*(F_k, Y) \simeq *$ .) For a spectrum  $E$ , if  $g$  is an  $E^*$ -equivalence (resp.,  $E_*$ -equivalence) and  $F_k$  is  $E^*$ -acyclic (resp.,  $E_*$ -acyclic), then so is  $h$ .*

*Proof.* We will give the proof for the case  $\text{map}(-, -)$  only; other cases can be proved as in [B, Theorem 4.6].

Case 1: Assume  $X \simeq X'$ . Then the diagram can be replaced (up to weak equivalences) by

$$\begin{array}{ccc} \int_K F & \longrightarrow & K \\ h \downarrow & & 1 \downarrow \\ \int_K F' & \longrightarrow & K \end{array}$$

for some bounded diagrams  $F$  and  $F'$ , where  $K \simeq X' \simeq X$ ,  $F(\sigma) \simeq F$  and  $F'(\sigma) \simeq F'$  for each  $\sigma \in K$ . We proceed by induction on the dimension of  $K$ . If  $\dim K = 0$ , it is clear that Case 1 is true. Suppose  $K = L \cup_{\Delta[n]} \Delta[n]$ ,  $\dim L < n$  and  $\text{map}(l, Y): \text{map}(\mathcal{f}_L F', Y) \rightarrow \text{map}(\mathcal{f}_L F, Y)$  is a weak equivalence. Now by [C1, 3.13],  $h: \mathcal{f}_K F \rightarrow \mathcal{f}_K F'$  is the homotopy push-out of the following diagram:

$$\begin{array}{ccccc} \mathcal{f}_L F & \longleftarrow & \dot{\Delta}[n] \times F(\tau) & \longrightarrow & \Delta[n] \times F(\tau) \\ \downarrow l & & \downarrow 1 \times g & & \downarrow 1 \times g \\ \mathcal{f}_L F' & \longleftarrow & \dot{\Delta}[n] \times F'(\tau) & \longrightarrow & \Delta[n] \times F'(\tau) \end{array}$$

where  $\tau$  is the distinguished  $n$ -simplex in  $\Delta[n]$ . Since  $\text{map}(1 \times g, Y)$ 's are weak equivalences, the homotopy push-out  $h$  also induces a weak equivalence in  $\text{map}(-, Y)$ . This finishes the proof of Case 1.

Case 2: Assume the right hand square in Theorem 1.1 is a homotopy pull-back. Then  $F \simeq F'$ , and the right hand square can be replaced (up to weak equivalences) by

$$\begin{array}{ccc} \mathcal{f}_K F \times G & \longrightarrow & \mathcal{f}_K G \\ h \downarrow & & k \downarrow \\ \mathcal{f}_K F & \longrightarrow & K \end{array}$$

for some bounded diagrams  $F$  and  $G$ , where  $K \simeq X'$ ,  $G(\sigma) = F_k$ ,  $F(\sigma) \simeq F \simeq F'$  and  $(F \times G)(\sigma) = G(\sigma) \times F(\sigma)$  for each  $\sigma \in K$ . Again we proceed by induction on the dimension of  $K$ . If  $\dim K = 0$ , it is clear that Case 2 is true. Suppose  $K = L \cup_{\Delta[n]} \Delta[n]$ ,  $\dim L < n$  and  $\text{map}(F_k, Y) \simeq Y$ . Now by [C1, 3.13],  $h: \mathcal{f}_K F \times G \rightarrow \mathcal{f}_K F$  is the homotopy push-out of the diagram

$$\begin{array}{ccccc} \mathcal{f}_L F \times G & \longleftarrow & \dot{\Delta}[n] \times F(\tau) \times G(\tau) & \longrightarrow & \Delta[n] \times F(\tau) \times G(\tau) \\ \downarrow l & & \downarrow m & & \downarrow n \\ \mathcal{f}_L F & \longleftarrow & \dot{\Delta}[n] \times F(\tau) & \longrightarrow & \Delta[n] \times F(\tau) \end{array}$$

where  $\tau$  is the distinguished  $n$ -simplex in  $\Delta[n]$ . Using the adjunction of the mapping space  $\text{map}(-, -)$ , it is easy to see that  $\text{map}(m, Y)$  and  $\text{map}(n, Y)$  are weak equivalences. By induction,  $\text{map}(l, Y)$  is also a weak equivalence. Hence,  $\text{map}(h, Y)$  is a weak equivalence. This finishes the proof of Case 2.

General case: Let  $P$  be the homotopy pull-back of  $E' \rightarrow X'$ , and  $k: X \rightarrow X'$ . Then by Case 2,  $i: P \rightarrow E'$  induces a weak equivalence on  $\text{map}(-, Y)$ . Since the fiber of  $P \rightarrow X$  is  $F'$ , the induced map from  $F$  to  $F'$  is  $g$  itself. Hence, we have the following commutative diagram, and it satisfies Case 1:

$$\begin{array}{ccc} F & \longrightarrow & E \\ g \downarrow & & \downarrow j \\ F' & \longrightarrow & P. \end{array}$$

By Case 1,  $\text{map}(j, Y)$  is a weak equivalence. Since the required map  $h$  is the composite  $i \circ j$  for which both  $i$  and  $j$  induce weak equivalences on  $\text{map}(-, Y)$ ,  $\text{map}(h, Y)$  is a weak equivalence.  $\square$

*Remarks.* 1. The difference between the assumptions of Theorem 1.1 and [B, Theorem 4.6] is that we assume  $\text{map}(F_k, Y) \simeq Y$  while Bousfield assumes that  $\text{map}(\Omega k, Y)$  is a weak equivalence. Our assumption is actually weaker. Indeed, consider the principle fibration  $\Omega X \rightarrow \Omega X' \rightarrow F_k$ . We know that  $F_k$  can be built as a homotopy colimit from the cofiber  $C_{\Omega k}$  of the map  $\Omega k$  (cf. [C2, Corollary 9.2]). So, if  $\text{map}(\Omega k, Y)$  is a weak equivalence, then  $\text{map}(C_{\Omega k}, Y) \simeq Y$ . Hence,  $\text{map}(F_k, Y) \simeq Y$ . Here is an example of a case when  $\text{map}(F_k, Y) \simeq Y$  but  $\text{map}(\Omega k, Y)$  is not a weak equivalence. Consider the trivial fiber sequence

$$S^2 \xrightarrow{r} S^2 \times S^1 \xrightarrow{k} S^1,$$

where  $r$  is the inclusion to the first factor of  $S^2 \times S^1$  and  $k$  is the projection to the second factor of  $S^2 \times S^1$ . Take  $Y = S^1$ . It is clear that  $\text{map}_*(S^2, S^1) \simeq *$ , and since  $S^1$  is connected,  $\text{map}(S^2, S^1) \simeq S^1$ . Now, if  $\text{map}(\Omega k, S^1)$  were a weak equivalence,  $\text{map}_*(\Omega k, S^1)$  would be a weak equivalence too. However,  $\text{map}_*(\Omega S^1, S^1)$  is connected but  $\text{map}_*(\Omega(S^2 \times S^1), S^1)$  is not. Thus,  $\text{map}(\Omega k, S^1)$  is not a weak equivalence.

2. We may ask whether the condition  $\text{map}(F_k, Y) \simeq Y$  (or  $F_k$  is  $E_*$ -acyclic) can be further weakened to the condition that  $\text{map}(k, Y)$  is a weak equivalence (or  $k$  is a  $E_*$ -equivalence). The following example shows that this cannot be done. Consider the following maps between homotopy fiber sequences:

$$\begin{array}{ccccc} K(\mathbb{Z}/p^2, 1) & \longrightarrow & K(\mathbb{Z}/p, 1) & \longrightarrow & K(\mathbb{Z}/p, 2) \\ id \downarrow & & \downarrow & & k \downarrow \\ K(\mathbb{Z}/p^2, 1) & \longrightarrow & * & \longrightarrow & K(\mathbb{Z}/p^2, 2) \end{array}$$

where  $k$  is induced by the inclusion  $\mathbb{Z}/p \rightarrow \mathbb{Z}/p^2$ . Since both  $K(\mathbb{Z}/p, 2)$  and  $K(\mathbb{Z}/p^2, 2)$  are complex  $K$ -theory acyclic, the map  $k: K(\mathbb{Z}/p, 2) \rightarrow K(\mathbb{Z}/p^2, 2)$  is a complex  $K$ -theory equivalence. However, the space  $K(\mathbb{Z}/p, 1)$  is not complex  $K$ -theory acyclic.

3. Zabrodsky's Lemma in its original form is obtained if we take  $* \rightarrow X \rightarrow X$  for the fiber sequence  $F' \rightarrow E' \rightarrow X'$  in Theorem 1.1.

## 2. APPLICATIONS

We are going to list some applications in  $f$ -localization theory. Let us recall the definition of an  $f$ -localization functor  $L_f$ . Fix a map  $f: W \rightarrow V$  between spaces. A space  $T$  is called  $f$ -local if it is fibrant and the map

$$\text{map}(f, T): \text{map}(V, T) \rightarrow \text{map}(W, T)$$

is a weak equivalence. A map  $g: C \rightarrow D$  is called an  $L_f$ -equivalence if the map  $\text{map}(g, T): \text{map}(D, T) \rightarrow \text{map}(C, T)$  is a weak equivalence for every  $f$ -local space  $T$ . For a space  $Y$ , an  $f$ -localization of  $Y$  is a map  $\eta: Y \rightarrow L_f Y$  which is an  $L_f$ -equivalence and for which  $L_f Y$  is  $f$ -local. If the map  $f$  is  $W \rightarrow *$ , we call  $f$ -local spaces  $W$ -null and  $L_f$ -equivalence maps  $P_W$ -equivalences. We write  $P_W$  for  $L_f$  and call  $P_W X$  a  $W$ -nullification of  $X$ . Since  $L_f Y$  (resp.,  $P_W Y$ ) is clearly unique up to homotopy, we call it the  $f$ -localization (resp.,  $W$ -nullification) of  $Y$ .

**Corollary 2.1.** *For any connected spaces  $W$  and  $X$ , let  $\eta: X \rightarrow P_W X$  be the  $W$ -nullification map of  $X$ . If  $\pi_1(\eta)$  is an isomorphism, then  $P_W(X\langle 1 \rangle) \simeq (P_W X)\langle 1 \rangle$ , where  $X\langle 1 \rangle$  is the simply connected cover of  $X$ .*

*Proof.* Consider the following diagram:

$$\begin{array}{ccccc}
 X\langle 1 \rangle & \longrightarrow & X & \longrightarrow & K(\pi_1 X, 1) \\
 \mu \downarrow & & \eta \downarrow & & \simeq \downarrow \\
 (P_W X)\langle 1 \rangle & \longrightarrow & P_W X & \longrightarrow & K(\pi_1 P_W X, 1).
 \end{array}$$

The fiber of  $\eta$  is  $P_W$ -acyclic (i.e.  $P_W F_\eta \simeq *$ ) by [D, Theorem 1.H.2]. Hence, by Theorem 1.1, the induced map  $\mu: X\langle 1 \rangle \rightarrow (P_W X)\langle 1 \rangle$  is a  $P_W$ -equivalence. From the principle fibration  $K(\pi_1 P_W X, 0) \rightarrow (P_W X)\langle 1 \rangle \rightarrow P_W X$ , since  $K(\pi_1 P_W X, 0)$  is always  $W$ -null,  $(P_W X)\langle 1 \rangle$  is also  $W$ -null. Hence,  $\mu$  is the  $W$ -nullification map of  $X\langle 1 \rangle$ , so  $P_W(X\langle 1 \rangle) \simeq (P_W X)\langle 1 \rangle$ .  $\square$

*Remarks.* 1. It is clear from the proof of Corollary 2.1 that if  $\pi_j(\eta)$  is an isomorphism for  $j \leq n$ , then  $P_W(X\langle j \rangle) \simeq (P_W X)\langle j \rangle$  for  $j \leq n$ .

2. The interest in this corollary lies in the fact that the localization of a simply connected space is usually easier to compute.

**Corollary 2.2.** *Consider a homotopy cofiber sequence  $A \xrightarrow{g} B \xrightarrow{h} C_g$  with  $A$  and  $B$  connected. For any map  $f$ , if  $L_f F_h \simeq *$  and the natural map  $F_g \rightarrow \Omega C_g$  is an  $L_f$ -equivalence, then  $L_f A \simeq *$ .*

*Proof.* Apply Theorem 1.1 to the following diagram between homotopy fiber sequences:

$$\begin{array}{ccccc}
 F_g & \longrightarrow & A & \xrightarrow{g} & B \\
 \downarrow & & \downarrow & & h \downarrow \\
 \Omega C_g & \longrightarrow & * & \longrightarrow & C_g.
 \end{array}$$

$\square$

The following corollary improves the result [D, Theorem 3.D.2] of Dror Farjoun, which has several important special cases (cf. [D, Corollary 3.D.3]).

**Corollary 2.3.** *Suppose given a homotopy fiber sequence  $F \rightarrow E \rightarrow X$  with  $E$  and  $X$  connected. Let  $F_\eta$  be the homotopy fiber of the  $f$ -localization map  $\eta$  of  $E$ . If  $L_{\Sigma f} X \simeq L_f X$  and  $L_f F_\eta \simeq *$ , then  $L_f F \rightarrow L_f E \rightarrow L_f X$  is a homotopy fiber sequence.*

*Proof.* Consider the following commutative diagram:

$$\begin{array}{ccccccc}
 \Omega X & \longrightarrow & F & \longrightarrow & E & \xrightarrow{g} & X \\
 u \downarrow & & \downarrow & & \downarrow & & \downarrow \\
 \Omega L_f X & \longrightarrow & F' & \longrightarrow & L_f E & \xrightarrow{L_f(g)} & L_f X
 \end{array}$$

where  $F'$  is the homotopy fiber of  $L_f(g)$ . Since  $L_{\Sigma f} X \simeq L_f X$ , it follows that  $\Omega L_f X \simeq \Omega L_{\Sigma f} X \simeq L_f \Omega X$  by [B, Theorem 3.1] or [D, Theorem 3.A.1]. Thus,  $u$  is an  $L_f$ -equivalence. By Theorem 1.1, the map  $F \rightarrow F'$  is also an  $L_f$ -equivalence, since  $L_f F_\eta \simeq *$ . Clearly,  $F'$  is  $f$ -local, since  $F'$  is the homotopy fiber of two  $f$ -local spaces. Consequently,  $F \rightarrow F'$  is the  $f$ -localization of  $F$ , and we have a homotopy fiber sequence  $L_f F \rightarrow L_f E \rightarrow L_f X$ .  $\square$
