HARMONIC MAPS WITH NONCONTACT BOUNDARY VALUES

HAROLD DONNELLY

(Communicated by Peter Li)

Abstract. Every rank one symmetric space \( M \), of noncompact type, admits a compactification \( \mathcal{M} \) by attaching a sphere \( S^{n-1} \) at infinity. If \( M \) does not have constant sectional curvature, then \( \mathcal{M} - M \) admits a natural contact structure. This paper presents a number of harmonic maps \( h \), from \( M \) to \( M \), which extend continuously to \( \mathcal{M} \), and have noncontact boundary values. If the boundary values are assumed continuously differentiable, then the contact structure must be preserved.

1. Introduction

Suppose that \( M \) is a complete simply connected manifold of negative curvature. Then \( M \) is diffeomorphic to \( \mathbb{R}^n \) and \( M \) admits a natural compactification \( \mathcal{M} \), by adding a sphere \( S^{n-1} \) at infinity. Given a continuous map \( f : S^{n-1} \rightarrow S^{n-1} \), the Dirichlet problem at infinity is to find a harmonic map \( h : M \rightarrow M \) which continuously assumes the boundary values \( f \) on \( S^{n-1} \).

Let \( M \) be a rank one symmetric space, other than the hyperbolic space. The sphere \( \mathcal{M} - M \) then admits a generalized contact structure. In [2], it was shown that if \( h \in C^2(M, M) \cap C^1(\mathcal{M}, \mathcal{M}) \) is harmonic, then its boundary value \( f \) is a contact transformation. More generally, if \( h \) is only defined in a neighborhood of some boundary point \( p \in \mathcal{M} - M \), then \( f \) is locally a contact transformation.

The purpose of the present paper is to show that it is necessary to suppose that the boundary values of \( h \) are assumed continuously differentiably in order to guarantee that \( f \) is contact, even in a weak sense. In fact, \( f \) will be continuously differentiable and noncontact, so \( f \) cannot satisfy any reasonable notion of weakly contact. In Proposition 3.5, we give an explicit example of a harmonic map \( h \in C^2(M, M) \cap C^0(\mathcal{M} - \infty) \) having noncontact boundary values \( f \). Here \( \infty \) denotes the point at infinity in the unbounded model. Section 4 extends the example of Proposition 3.5 by constructing an infinite family of such solutions. Finally, we show the existence of harmonic maps \( h \in C^2(M, M) \cap C^0(\mathcal{M}, \mathcal{M}) \) having noncontact boundary values. The existence proof of Section 5 does not provide an explicit solution, as in Proposition 3.5. However, the solution is shown to exist on all of \( \mathcal{M} \), not just \( \mathcal{M} - \infty \).
The techniques employed in this paper are developed from the earlier work of mathematicians who studied the lack of uniqueness in the Dirichlet problem for harmonic maps between hyperbolic spaces $H^n$, i.e., locally symmetric spaces of constant curvature $-1$. Li and Tam [4] and Wolf [6] constructed a family of proper harmonic maps $h : H^2 \to H^2$ having boundary value the identity on the circle at infinity. Economakis [3] generalized this result to $H^n$. The method of separation of variables is used to reduce the harmonic map equation to an ordinary differential equation. In higher dimensions, $n > 2$, the ordinary differential equation is much more difficult to solve.

2. Boundary values assumed smoothly

Let $M$ be a rank one symmetric space of noncompact type. We exclude the case where $M$ has constant negative sectional curvature. The unbounded model of $M$ is $(0, \infty) \times N$, where $N$ is a two term nilpotent group. The Lie algebra $\mathfrak{n}$ of $N$ decomposes as $\mathfrak{n} = \mathfrak{n}_1 \oplus \mathfrak{n}_2$, where $\mathfrak{n}_2$ is central in $\mathfrak{n}$ and $[\mathfrak{n}_1, \mathfrak{n}_1] \subseteq \mathfrak{n}_2$. The Cayley transform identifies the compactification $\overline{M}$ of $M$ with $[0, \infty) \times N \cup \{\infty\}$, where $\{\infty\}$ denotes the point at infinity.

For the unbounded model, the metric of $M$ may be realized as a doubly warped product

$$(2.1) \quad g_M = \left(\frac{dy}{y}\right)^2 + y^{-2}g_{n_1} + y^{-4}g_{n_2}.$$ 

Here $y \in (0, \infty)$ is the coordinate on the first factor of $R^+ \times N$. In this paper, we use indices $0 \leq j \leq n_1 + n_2$. The index 0 refers to $\partial/\partial y$, the indices $1 \leq j \leq n_1$ refer to the $g_{n_1}$ part of (2.1), and the indices $n_1 + 1 \leq j \leq n_1 + n_2$ refer to the $g_{n_2}$ part of (2.1).

Suppose that $h : M \to M$ is a $C^2$ map. The differential $dh$ is a section of $T^*M \otimes h^{-1}TM$. The Levi-Civita connection of $M$ induces a natural connection $\nabla$ on $T^*M \otimes h^{-1}TM$. So one has

$$\nabla dh \in \Gamma(T^*M \otimes T^*M \otimes h^{-1}TM).$$

The tension field $\tau(h) = Tr(\nabla dh) \in \Gamma(h^{-1}TM)$ is obtained by taking the trace in the first two factors. We say that $h$ is harmonic when its tension field vanishes identically.

We will need an explicit formula for $\tau(h)$ in the special case of the metric given by (2.1). Choose an orthonormal basis $X_1, X_2, \ldots, X_{n_1}$ for $\mathfrak{n}_1$ and an orthonormal basis $Z_1, Z_2, \ldots, Z_{n_2}$ for $\mathfrak{n}_2$, relative to the left invariant metric on $N$. One has

$[X_i, Z_j] = [Z_i, Z_j] = 0$ and $[X_i, X_j] = \sum_k a_{ij}^k Z_k$,

for some structure constants $a_{ij}^k$. We choose a frame field $e_i$ on $M$ to consist of $e_0 = \partial/\partial y$, $e_i = X_i$, $1 \leq i \leq n_1$, and $e_i = Z_{i-n_1}$, $n_1 + 1 \leq i \leq n_1 + n_2$. Of course, $e_i$ is orthogonal but not orthonormal relative to the metric given by (2.1). If $e_i^*$ is the dual coframe field, then the differential of $h$ has components $dh = \sum_{i,j} h_{ij}^k e_i^* \otimes e_j$.

Similarly, the metric on the cotangent bundle has components $g^{ij} = \langle e_i^*, e_j^* \rangle$. We denote $h_{ij}^k = e_j h_i^k$ to be the derivatives of the $h_i^k$ in the direction $e_j$. 

License or copyright restrictions may apply to redistribution; see https://www.ams.org/journal-terms-of-use
The tension field $\tau(h)$ is a section of $h^{-1}TM$. We denote the normal variable on the image by $\overline{y} = y \circ h$. In [2], the components of $\tau(h)$ were calculated explicitly as

\[(2.2)\]
\[
\tau^0(h) = g^{ij}h_{ij}^0 + (1 - n_1 - 2n_2)h_{00}^0y - g^{ij}h_{ij}^0\overline{y}^{-1} + g^{ij}\sum_{\gamma=1}^{n_1} h_{ij}^\gamma \overline{y}^{-1} + g^{ij}\sum_{\gamma=n_1+1}^{n_1+n_2} 2h_{ij}^\gamma \overline{y}^{-3},
\]
\[
\tau^\alpha(h) = g^{ij}h_{ij}^\alpha + (1 - n_1 - 2n_2)h_{00}^\alpha y - 2g^{ij}h_{ij}^0\overline{y}^{-1} + g^{ij}\sum_{\beta=1}^{n_1} \sum_{\gamma=n_1+1}^{n_1+n_2} a_{\alpha\beta}^\gamma h_{ij}^\gamma \overline{y}^{-2}, \quad 1 \leq \alpha \leq n_1,
\]
\[
\tau^\alpha(h) = g^{ij}h_{ij}^\alpha + (1 - n_1 - 2n_2)h_{00}^\alpha y - 4g^{ij}h_{ij}^0\overline{y}^{-1}, \quad n_1 + 1 \leq \alpha \leq n_1 + n_2.
\]

Here $j$ is summed from 0 to $n_1 + n_2$. Observe that $\dim M = n_1 + n_2 + 1$.

Suppose that $U$ is a neighborhood of some boundary point $p \in 0 \times N$. Let $h : U \cap \mathbb{M} \to \mathbb{M}$ be a harmonic map having boundary values $f : U \cap (0 \times N) \to 0 \times N$. We say that $f$ is a contact transformation if it is continuously differentiable and $df$ satisfies $f_j^0 = 0$, $1 \leq j \leq n_1$, $n_1 + 1 \leq \gamma \leq n_1 + n_2$. Equivalently, $df(n_1) \subset n_1$. The following result was derived in [2].

**Theorem 2.3.** Suppose that $h \in C^2(U \cap \mathbb{M}, M) \cap C^1(U \cap \mathbb{M}, \mathbb{M})$ is a harmonic map with boundary values $f \in C^1(U \cap (0 \times N), 0 \times N)$. Then $f$ is a contact transformation.

For the convenience of the reader, we sketch the proof of Theorem 2.3. Assume that $h \in C^2(U \cap \mathbb{M}, \mathbb{M})$. The result then follows by multiplying formula (2.2) for $\tau^0(h)$ by $\overline{y}^3/\overline{y}^2$ and letting $y \to 0$. Under the weaker hypothesis that $h \in C^1(U \cap \mathbb{M}, \mathbb{M})$, more work is required. One uses the divergence theorem on small balls and passage to a subsequence to handle the second order terms in (2.2). Full details of the proof are given in [2].

3. **Nonlinear Ordinary Differential Equations**

In general, it seems formidable to construct solutions to the harmonic map equation $\tau(h) = 0$, where $\tau(h)$ is given by (2.2). However, if the boundary value $f : N \to N$ is a Lie group homomorphism, then the problem simplifies considerably. After imposing an additional algebraic condition, which appears as (3.2) below, one is reduced to solving a nonlinear ordinary differential equation.

Suppose that $f : N \to N$ is a differentiable map. Let $Y_i$ be a left invariant frame field on $TN$. We may write $df(Y_i(x)) = \sum_j b_{ij}(x)Y_j(f(x))$, for each $x \in N$. Here $Y_i(x)$ belongs to the tangent space $T_xN$ at $x$. We say that the components of $df$ are constant in the left invariant frame field $Y_i$ if $b_{ij}(x) = b_{ij}(e)$, for all $x \in N$, where $e$ is the identity element of the group $N$. It is easy to verify that if the components of $df$ are constant in some left invariant frame field, then the components of $df$ are constant in any left invariant frame field. The following elementary observation is very useful:

**Proposition 3.1.** Suppose that $f : N \to N$ is a Lie group homomorphism. Then the components of $df$ are constant in any left invariant frame field.
Proof. Let \( f : N \rightarrow N \) be any differentiable map. One has \( Y_i(x) = x_*Y_i(e) \), where \( x_* \) is the differential of left translation by \( x \). Therefore

\[
df(x_*Y_i(e)) = \sum_j b_{ij}(x)(f(x))_*Y_j(e),
\]

\[
df(Y_i(e)) = \sum_j b_{ij}(e)(f(e))_*Y_j(e).
\]

The condition \( b_{ij}(x) = b_{ij}(e) \) is therefore equivalent to

\[
(f(x))_*^{-1} \circ df \circ x_* = (f(e))_*^{-1} \circ df
\]

where each side is an endomorphism of \( T_e N \).

If \( f : N \rightarrow N \) is a Lie group homomorphism, then \( f(e) = e \), so the above condition reduces to

\[
df \circ x_* = (f(x))_* \circ df.
\]

The definition of homomorphism is that \( f(xy) = f(x)f(y) \). We now replace \( y \) by a one parameter group \( y = \exp(tY) \) and differentiate in \( t \).

Assume now that \( f : N \rightarrow N \) is a Lie group homomorphism. Define a map \( h : R^+ \times N \rightarrow R^+ \times N \) by setting \( h(y, n) = (g(y), f(n)) \). The tension field \( \tau(h) \) of \( h \) is given by the equations (2.2). Suppose that the boundary value of \( f \) satisfies the algebraic condition

\[
g_{1 \leq \alpha \leq n_1} \sum_{j=1}^{n_1+n_2} g^\beta \sum_{\beta=1}^{n_1} \sum_{\gamma=n_1+1}^{n_1+n_2} a_{\alpha\beta}^\gamma f_j^\beta f_j^\gamma = 0
\]

for \( 1 \leq \alpha \leq n_1 \). Then \( h \) is harmonic if and only if \( g \) satisfies the following ordinary differential equation:

\[
y^2g''(y) + (1 - n_1 - 2n_2)yg'(y) - y^2(g'(y))^2(g(y))^{-1}
\]

\[
+ y^2 \left[ \sum_{j=1}^{n_1+n_2} f_j^1 f_j^2 + y^2 \sum_{j=n_1+1}^{n_1+n_2} f_j^1 f_j^2 \right] (g(y))^{-1}
\]

\[
+ 2y^2 \left[ \sum_{j=1}^{n_1+n_2} f_j^1 f_j^2 + y^2 \sum_{j=n_1+1}^{n_1+n_2} f_j^1 f_j^2 \right] (g(y))^{-3} = 0.
\]

Recall that the \( f_j^2 \) are constant by Proposition 3.1. In order for \( h \) to solve the Dirichlet problem, with boundary value \( f : N \rightarrow N \), we must impose the boundary condition \( g(0) = 0 \).

If \( Z \) denotes the center of \( N \), then \( N/Z \) is abelian. By choosing \( f \) to be a suitable composition of homomorphisms \( N \rightarrow N/Z \rightarrow N \), we achieve \( f_j^{n_1+1} = 1 \) and all other \( f_j^{n_2} = 0 \), for any given \( N \). In this special case, equation (3.3) reduces to

\[
g^2(y)g''(y) - \frac{m}{y} g^2(y)g'(y) - \frac{3}{2} g^2(y)(g'(y))^2 + 2 = 0
\]

with \( m = n_1 + 2n_2 - 1 \geq 3 \). This leads to simple explicit examples of harmonic maps having noncontact boundary values:
Proposition 3.5. Assume that \( f : N \rightarrow N \) is a Lie group homomorphism satisfying \( f_1^{n+1} = 1 \) and \( f_j^\alpha = 0 \) if \( j \neq 1 \) or \( \alpha \neq n_1 + 1 \). Define
\[
h(y, n) = \left( \sqrt[4]{\frac{4}{m+1}} y^\frac{1}{2}, f(n) \right).
\]
Then \( h : R^+ \times N \rightarrow R^+ \times N \) is a harmonic map which assumes the boundary values \( f \) continuously.

Proof. In view of the discussion above, one just needs to verify that \( g(y) = \sqrt[4]{\frac{4}{m+1}} y^\frac{1}{2} \) satisfies (3.4). This is an elementary calculation. \( \square \)

4. Family of solutions

The harmonic map constructed in Proposition 3.5 is quite special, since it is based on solving the nonlinear differential equation (3.4) in closed form. In this section, we construct an infinite family of harmonic maps, all having the same boundary value \( f \), which extend the solution of Proposition 3.5. Our approach is based upon the work of Economakis [3]. He extended the identity map of hyperbolic space to an infinite family of maps, all agreeing with the identity map on the boundary.

The first step is a formal perturbation expansion near \( y = 0 \). We seek an approximate solution to (3.4) given by
\[
g(y) \sim \sqrt[4]{\frac{4}{m+1}} (y^\frac{1}{2} + ay^\nu)
\]  
for some constants \( \nu > \frac{1}{2} \) and \( a \). Substituting into (3.4), the highest order term leads to the quadratic equation
\[
\nu^2 - (m+2)\nu - \left( \frac{6m+5}{4} \right) = 0.
\]
Only one of the roots is positive, so we must take \( 2\nu = |m+2+\sqrt{(m+2)^2+6m+5}| \). Since \( m \geq 3 \), the required condition \( \nu > \frac{1}{2} \) holds. The constant \( a \) may be chosen arbitrarily.

With this choice of \( \nu \), we try a higher order correction
\[
g(y) \sim \sqrt[4]{\frac{4}{m+1}} (y^\frac{1}{2} + ay^\nu + by^s)
\]
for \( b \) and \( s > \nu \) constants. Calculating the derivatives and retaining the highest order terms in (3.4), leads to \( s = 2\nu - \frac{1}{2} \) and
\[
b = -\left( s^2 - (m+2)s - \frac{6m+5}{4} \right)^{-1} (2\nu^2 - 5\nu - 3m\nu - 3m/2 - 1)a^2.
\]
Note that \( \nu > \frac{1}{2} \) ensures that \( s > \nu \).

Following the technique of [3], we use the contraction mapping principle to establish rigorously that there is a solution of (3.4), with the asymptotic behavior (4.1), defined near \( y = 0 \). Define new dependent variables \( v \) and \( w \) by
\[
g' = \frac{1}{2} y^{-\frac{1}{2}} + v,
\]
\[
v = cy^{\nu-\frac{s}{2}} + w.
\]
Using (4.1), we expect \( c = a(\nu - \frac{1}{2}) \). Also, the function \( w \) should vanish to order \( 2\nu - 2 \) at \( y = 0 \). It follows that

\[
(4.2) \quad g(y) = \sqrt[4]{\frac{4}{m + 1}} y^{\frac{1}{2}} \exp(\int_0^y v(t) dt).
\]

The second order nonlinear differential equation (3.4) for \( g \) is equivalent to the following integral-differential equation for \( v \):

\[
(4.3) \quad \frac{d}{dy} (y^{-m} v) = \left( \frac{m + 1}{2} \right) y^{-m-2} (1 - \exp(-4 \int_0^y v(t) dt)).
\]

Changing the dependent variable from \( v \) to \( w \) gives

\[
(4.4) \quad \frac{d}{dy} (y^{-m} w) = \left( \frac{m + 1}{2} \right) y^{-m-2} \left( 1 - \exp \left( -4 \int_0^y w(t) dt - 4c \left( \nu - \frac{1}{2} \right)^{-1} y^{\nu-\frac{1}{2}} \right) \right)
- c \left( \nu - m - \frac{3}{2} \right) y^{\nu-m-\frac{1}{2}}.
\]

Consider the complete metric space, defined for given positive constants \( K \) and \( \epsilon \) by

\[
\Lambda^{2\nu-2}_{\epsilon,K} = \{ w \in C(0, \epsilon) \mid \sup_{0 < y < \epsilon} |y^{2-2\nu} w(y)| \leq K \}
\]

with

\[
\|w\|^{2\nu-2}_{\epsilon} = \sup_{0 < y < \epsilon} |y^{2-2\nu} w(y)|.
\]

Our formal calculation leads us to hope that, for any choice of \( c \), the equation (4.4) has a solution \( w \) belonging to \( \Lambda^{2\nu-2}_{\epsilon,K} \). This should give a family of solutions, parametrized by \( c \) or equivalently \( a \), to (3.4).

Define

\[
T w(x) = x^m \int_0^x \left[ \left( \frac{m + 1}{2} \right) y^{-m-2} \left( 1 - \exp \left( -4 \int_0^y w(t) dt - 4c \left( \nu - \frac{1}{2} \right)^{-1} y^{\nu-\frac{1}{2}} \right) \right)
- c \left( \nu - m - \frac{3}{2} \right) y^{\nu-m-\frac{1}{2}} \right] dy.
\]

It suffices to show that \( T \) is a contraction mapping on some \( \Lambda^{2\nu-2}_{\epsilon,K} \). Existence of a solution to (4.4) will then follow from the contraction mapping principle.

We first need to establish

**Proposition 4.5.** Suppose that the parameter \( c \) is fixed. For \( K(c) \) sufficiently large and \( \epsilon = \epsilon(c, K) \) sufficiently small, \( T \) maps \( \Lambda^{2\nu-2}_{\epsilon,K} \) into itself.

**Proof.** Define variables \( q \) and \( \psi \) by

\[
q = \exp(-4 \int_0^y w(t) dt) - 1,
\]

\[
\psi = \exp(-4c(\nu - \frac{1}{2})^{-1} y^{\nu-\frac{1}{2}}) - 1 + 4c(\nu - \frac{1}{2})^{-1} y^{\nu-\frac{1}{2}}.
\]
It is straightforward to estimate the norms of these functions in the space $\Lambda^{2\nu-1}_{c,K}$,

$$\|\psi\|^{2\nu-1}_{\epsilon} \leq \frac{64\epsilon^2}{(2\nu - 1)^2},$$

$$\|q\|^{2\nu-1}_{\epsilon} \leq \frac{5}{2\nu - 1} \|w\|^{2\nu-2}_{\epsilon}.$$ 

Using the quadratic equation $\nu^2 - (m + 2)\nu - (6m + 5)/4 = 0$, one verifies that

$$Tw(x) = x^m \int_0^x \left( \frac{m+1}{2} \right) y^{-m-2} [g(4c(\nu - \frac{1}{2})^{-1}y^{\nu - \frac{1}{2}} - 1) - \psi(1 + q)] dy.$$ 

Thus

$$|Tw(x)| \leq x^{2\nu-2} \left( \frac{m+1}{2} \right) \left( 1 + 4|c|\epsilon^{\nu - \frac{1}{2}} \right) \left( \frac{1}{2\nu - m - 2} \right) \|q\|^{2\nu-1}_{\epsilon}$$

$$+ x^{2\nu-2} \left( \frac{m+1}{2} \right) \|\psi\|^{2\nu-1}_{\epsilon} \exp \left( 4\|w\|^{2\nu-2}_{\epsilon} \frac{\epsilon^{2\nu-1}}{2\nu-1} \right) (2\nu - m - 2)^{-1}.$$ 

If $\|w\|^{2\nu-2}_{\epsilon} \leq K$, this gives

$$\|Tw\|^{2\nu-2}_{\epsilon} \leq \left( \frac{5(m+1)K}{2} \right) (2\nu - 1)^{-1} (2\nu - m - 2)^{-1} (1 + 4|c|\nu^{-2}) \epsilon^{\nu - \frac{1}{2}}$$

$$+ 32(m+1)\epsilon^2 (2\nu - 1)^{-2}(2\nu - m - 2)^{-1} \exp(4K(2\nu - 1)^{-1} \epsilon^{2\nu-1}).$$

Since $5(m+1) < 2(2\nu - 1)(2\nu - m - 2)$, we may choose $K(c)$ sufficiently large and $\epsilon = \epsilon(c, K)$ sufficiently small to guarantee that $\|Tw\|^{2\nu-2}_{\epsilon} \leq K$. Therefore $T$ maps the space $\Lambda^{2\nu-2}_{c,K}$ into itself.

Suppose that $K$ is determined so that the hypothesis of Proposition 4.5 holds. It remains to show that $T$ is a contraction mapping on $\Lambda^{2\nu-2}_{c,K}$. One has

$$|Tw_1(x) - Tw_2(x)|$$

$$\leq x^{m} \int_0^x \left( \frac{m+1}{2} \right) y^{-m-2} \exp(-4c(\nu - \frac{1}{2})^{-1}y^{\nu - \frac{1}{2}}) \exp \left( -4 \int_0^y w_1(t) dt \right)$$

$$- \exp \left( -4 \int_0^y w_2(t) dt \right) dy.$$ 

For sufficiently small $\epsilon$, this gives

$$\|Tw_1 - Tw_2\|^{2\nu-2}_{\epsilon} \leq 4(m+1)(2\nu - m - 2)^{-1}(2\nu - 1)^{-1} \|w_1 - w_2\|^{2\nu-2}_{\epsilon}.$$ 

Since $4(m+1) < (2\nu - m - 2)(2\nu - 1)$, we have a contraction mapping $T : \Lambda^{2\nu-2}_{c,K} \rightarrow \Lambda^{2\nu-2}_{c,K}$.

The results proved above give a family of solutions $w_c$ to the integral-differential equation (4.4). Taking

$$g_{\alpha}(y) = \sqrt{\frac{4}{m+1}} y^{\frac{1}{2}} \exp \left( \int_0^y \left[ w_{\alpha}(t) + ct^{\nu - \frac{1}{2}} \right] dt \right),$$

where $c = a(\nu - \frac{1}{2})$, gives a family of solutions to the second order nonlinear differential equation (3.4). Also, one has the asymptotic relation (4.1), which determines $\alpha$. So far, these solutions are only determined locally, near $y = 0$. 

To extend the domain of definition of \( g_a(y) \) to all \( y \geq 0 \), we assume that \( a \) is positive. Then \( v_c = cy^{\frac{a}{2}} + w_c \) is positive for sufficiently small \( y > 0 \). Let \( S \) be the supremum of all \( s > 0 \), so that \( v_c \) extends to a strictly positive solution of (4.3), on the interval \((0, s)\). By uniqueness for the ordinary differential equation (3.4), the extension \( v_c \) is unique.

If \( S \) is finite, then on the interval \((0, S)\) we have

\[
0 \leq \frac{d}{dy} (y^{-m} v) \leq \left( \frac{m + 1}{2} \right) y^{-m - 2}.
\]

Since \( y^{-m} v \) is increasing and bounded above on \((0, S)\), we have existence of a finite limit \( \lim_{y \to S} v(y) > 0 \). Using the integral formula (4.2), we deduce the existence of the limits \( \lim_{y \to S^-} g(y) \) and \( \lim_{y \to S^+} g'(y) \). Local existence theory for the equation (3.4) provides an extension of the solution \( g \) to \((0, S + \delta)\), for some \( \delta > 0 \). Consequently, the solution \( v \) of (4.3) extends to \((0, S + \delta)\). It follows that \( S \) is infinite.

The resulting family of harmonic maps is described in the following extension of Proposition 3.5:

**Proposition 4.6.** Assume that \( f : N \to N \) is a Lie group homomorphism satisfying \( f_1^{n+1} = 1 \) and \( f_j^\alpha = 0 \) for \( j \neq 1 \) or \( \alpha \neq n_1 + 1 \). Define, for \( a > 0 \),

\[
h_a(y, n) = (g_a(y), f(n))
\]

Then \( h_a : R^+ \times N \to R^+ \times N \) is a family of harmonic maps, all of which assume the same boundary value \( f \), continuously in \((y, n)\). The parameter \( a \) may be determined from the asymptotic behavior of \( g_a \), as \( y \) approaches zero,

\[
g_a(y) \sim y^{\frac{4}{m+1}} (y^{\frac{1}{2}} + ay^\nu), \quad \nu > \frac{1}{2}.
\]

## 5. Existence of global solutions

The purpose of the present section is to show the existence of harmonic self maps \( h \) of rank one symmetric spaces \( M \), which extend continuously to the closure \( \overline{M} \), and have noncontact boundary values \( f \). The explicit solution of Proposition 3.5, and the family of solutions constructed in Proposition 4.6, only extend continuously to \( \overline{M} - \infty = [0, \infty) \times N \). In fact, their boundary values \( f : N \to N \) do not extend continuously to \( N \cup \{\infty\} \to N \cup \{\infty\} \). The point is that in the examples considered above, the map \( f \) is a Lie group homomorphism, but not an automorphism.

Lie group automorphisms of \( N \) are in one to one correspondence with automorphisms of the Lie algebra \( n \). For any Lie group, an automorphism \( f \) of the Lie group induces an automorphism \( f_* \) of the corresponding Lie algebra. Since \( N \) is simply connected and nilpotent, \( \exp : n \to N \) is a diffeomorphism. Given \( f_* : n \to n \), one can define \( f \) by \( f(\exp v) = \exp(f_* v) \). It follows from the Campbell-Hausdorff formula that \( f : N \to N \) is a Lie group automorphism.

The differential \( f_* \) of an automorphism \( f : N \to N \) must preserve the center \( n_2 \) of the Lie algebra \( n = n_1 \oplus n_2 \). Thus the components \( f_j^\beta = 0 \), for \( 1 \leq \beta \leq n_1 \) and \( n_1 + 1 \leq j \leq n_1 + n_2 \). The required condition (3.2) reduces to

\[
\sum_{j=1}^{n_1} \sum_{\beta=1}^{n_1+1} \sum_{\gamma=n_1+1}^{n_1+n_2} a_{\alpha\beta}^{-1} f_j^\beta f_j^\gamma = 0
\]

for \( 1 \leq \alpha \leq n_1 \).
To show that there are examples of noncontact Lie algebra automorphisms satisfying (5.1), assume that \( f_j^\beta = \delta_{j\beta} \), for \( 1 \leq j, \beta \leq n_1 \). Then (5.1) becomes

\[
\sum_{j=1}^{n_1} \sum_{\gamma=n_1+1}^{n_1+n_2} a_{\alpha\beta} f_{\beta}^\gamma = 0.
\]

This represents \( n_1 \) linear equations, parametrized by \( 1 \leq \alpha \leq n_1 \), in the \( n_1n_2 \) unknowns \( f_\beta^\gamma \). Since the system is homogeneous, there exists a nontrivial solution provided \( n_2 > 1 \). The corresponding Lie algebra automorphism is given by \( f_\gamma(X_\gamma) = X_\gamma + \sum f_{\gamma}^\gamma Z_{\gamma-n_1} \) and \( f_\alpha(Z_\alpha) = Z_\alpha \). Since the \( Z_\alpha \) are central, \( f_\gamma \) clearly preserves the \( \gamma \) Lie bracket.

For a general automorphism \( f_\gamma \), the \( n_1 \times n_1 \) matrix \( f_j^\beta \), \( 1 \leq j, \beta \leq n_1 \), must be invertible. If \( n_2 = 1 \), then for each \( 1 \leq \alpha \leq n_1 \), there is a unique \( 1 \leq \beta \leq n_1 \), with \( a_{\alpha\beta} f_{\beta}^\gamma \neq 0 \), in the standard basis for the Lie algebra [5]. Thus (5.1) reduces to

\[
\sum_{j=1}^{n_1} f_j^\beta f_j^\beta = 0, \quad 1 \leq \beta \leq n_1.
\]

So \( f_j^\gamma = 0 \) and \( f_\gamma \) can only be the identity map. Therefore, one must have \( n_2 > 1 \) in order to find noncontact automorphisms satisfying (5.1).

Suppose that \( f : \mathbb{N} \to \mathbb{N} \) is a Lie group automorphism whose differential satisfies (5.1). We extend \( f \) to \( h : \mathbb{R}^+ \times \mathbb{N} \to \mathbb{R}^+ \times \mathbb{N} \) by \( h(y, n) = (g(y), f(n)) \). The requirement that \( h \) is harmonic reduces to the ordinary differential equation in \( g \), given by (3.3). We note that (3.3) is of the form

\[
y^2 g''(y) - myg'(y) - y^2(g'(y))^2(g(y))^{-1} + c_1y^2(g(y))^{-1} + 2[c_3y^2 + c_4y^4](g(y))^{-3} = 0.
\]

Here \( c_2 = \sum_{j=n_1+1}^{n_1+n_2} \sum_{\gamma=n_1+1}^{n_1+n_2} f_{\gamma}^\gamma f_{\gamma}^\gamma = 0 \), since \( f_\alpha \) must preserve the center of \( \mathfrak{n} \). All of the other \( c_i \) are positive constants. We require \( c_3 \) to be positive so that \( f \) is noncontact.

One may conveniently change the independent variable in our differential equation. Suppose that

\[
g(y) = \sqrt{-\frac{4c_3}{m+1}} \ y^\frac{1}{2}w(y) = by^\frac{1}{2}w(y).
\]

Then

\[
y^2 w^3 w'' - myw^3 w' - y^2 w^2 (w')^2 + \left( \frac{m+1}{2} \right) (1 - w^4) + a_1yw^2 + a_4y^2 = 0.
\]

Here \( a_1 = c_1 / b^2 \), \( a_4 = 2c_4 / b^4 \), with \( b = \sqrt{-\frac{4c_3}{m+1}} \). Clearly, \( a_1 \) and \( a_4 \) are positive.

Also, since \( c_3 = \sum_{j=1}^{n_1} \sum_{\gamma=n_1+1}^{n_1+n_2} f_{\gamma}^\gamma f_{\gamma}^\gamma \) and (5.2) is homogeneous, there exist noncontact automorphisms \( f \) so that \( a_1 \) and \( a_4 \) are arbitrarily small.

If \( w_1(y) = 1 \), then one has

\[
y^2 w_1^3 w_1'' - myw_1^3 w_1' - y^2 w_1^2 (w_1')^2 + \left( \frac{m+1}{2} \right) (1 - w_1^4) + a_1yw_1^2 + a_4y^2
\]

\[
= a_1y + a_4y^2 > 0.
\]
Consider the following modification of (5.3),

$$\frac{\partial}{\partial t} w^2 w''' - m w^2 w' - y^2 w^2 (w')^2 + \left( \frac{m+1}{2} \right) (1 - w^2) + a_1 y w^2 + a_4 y^2 = 0$$

provided $a_1$ and $a_4$ are sufficiently small.

This suggests that (5.3) should have a solution $w(y)$ satisfying $1 \leq w(y) \leq e^y$. For such a $w(y)$, the corresponding $g(y)$ satisfies $by^2 \leq g(y) \leq by^2 e^y$. So $h : R^+ \times N \to R^+ \times N$ will be a harmonic map, extending continuously to $\overline{M}$ with noncontact boundary values $f$.

We will apply Theorem 7.1 of [1] to show the existence of $w(y)$. Some care must be taken since (5.3) is not uniformly Lipschitz in $w'(y)$. Define, for small $\epsilon > 0$,

$$G(p) = \begin{cases} \frac{p^2}{\epsilon^2}, & |p| \leq \exp(-\epsilon), \\ \exp(-\epsilon)|p|, & |p| \geq \exp(-\epsilon). \end{cases}$$

Consider the following modification of (5.3),

$$(5.4) \quad y^2 w^3 w''' - m y w^3 w' - y^2 w^2 G(w') + \left( \frac{m+1}{2} \right) (1 - w^4) + a_1 y w^2 + a_4 y^2 = 0.$$ 

Assume that $a_1$ and $a_4$ are sufficiently small. Then (5.4) satisfies the hypotheses of Theorem 7.1 in [1], with subsolution $w_1(y) = y$ and supersolution $w_2(y) = e^y$, on the interval $(\epsilon, \epsilon^{-1})$. We deduce that (5.4) has a solution $w(y)$, for $\epsilon < y < \epsilon^{-1}$, satisfying the bounds $w_1(y) \leq w(y) \leq w_2(y)$.

To obtain a solution of (5.3), we need to establish an a priori bound for $|w'(y)|$. If $a > 0$, let

$$C_1(a) = \sup_{a/2 \leq y \leq a+1, \ w_1(y) \leq v \leq w_2(y)} \left( \frac{m+1}{2} \right) (1 - v^4) + a_1 y v^2 + a_4 y^2.$$ 

Clearly, for $\epsilon(a)$ sufficiently small, the solution $w(y)$, of (5.4), satisfies $y^2 w^3 w''' \geq y w^2 (m w w' + y G(w')) - C_1(a)$, for $y \in [a/2, a+1]$. Choose $D_1(a)$ so that $|w'(y)| \geq D_1(a)$ implies $w''(y) > 0$, for each $y \in [a/2, a+1]$. If $w'(a) \geq D_1(a)$, then $w'(y) \geq D_1(a)$, for $y \in [a, a+1]$. If $w'(a) \leq -D_1(a)$, then $w'(y) \leq -D_1(a)$, for $y \in [a/2, a]$. This is because the interval where the bound on $w'(y)$ holds is both open and closed.

Thus, the solution to (5.4), guaranteed by Theorem 7.1 of [1], satisfies $|w'(a)| \leq D_2(a)$ and $w_1(a) \leq w(a) \leq w_2(a)$. Letting $\epsilon \to 0$ and applying the Arzela-Ascoli theorem leads to a solution $w(y)$ of (5.3) satisfying $w_1(y) \leq w(y) \leq w_2(y)$, for all $0 < y < \infty$.

We summarize the main conclusion of this section as

**Proposition 5.5.** Let $M$ be a rank one symmetric space, with $n_2 > 1$. Then there exist harmonic maps $h : M \to M$, which extend continuously to the compactification $\overline{M}$, and assume noncontact boundary values $f$. 

The solutions, whose existence has just been established, are defined and continuous on all of $\overline{M}$. In previous sections, the harmonic maps found were only continuous on $\overline{M} - \infty$. However, the earlier methods were more constructive. In particular, the harmonic map of Proposition 3.5 is given quite explicitly.
