TIME DELAYED PARABOLIC SYSTEMS
WITH COUPLED NONLINEAR BOUNDARY CONDITIONS

C. V. PAO

(Communicated by David S. Tartakoff)

Abstract. The aim of this paper is to show the existence and uniqueness of a solution for a system of time-delayed parabolic equations with coupled nonlinear boundary conditions. The time delays are of discrete type which may appear in the reaction function as well as in the boundary function. The approach to the problem is by the method of upper and lower solutions for nonquasimonotone functions.

1. Introduction

Parabolic partial differential equations with time delays have been given considerable attention in recent years, and various methods have been used for studying the existence and stability of the problem (cf. [1,2,5,6,7,8,10,11,12,13,14,15]). Most of the earlier works are devoted to scalar parabolic equations using semi-group theory and functional analytic approach (cf. [2,7,12,14,15]). The work in [7] treats a coupled system of functional parabolic equations using the theory of dynamic flow for quasimonotone nondecreasing functions. Recently, the method of upper and lower solutions has been used to treat a class of time-delayed parabolic equations for mixed quasimonotone functions, including quasimonotone nondecreasing reaction functions (cf. [4,9,10]). In all the above works the boundary condition is linear and the time delays appear only in the reaction function. In this paper we consider a system of time-delayed parabolic equations with coupled nonlinear boundary conditions where the reaction function and boundary function are not necessarily quasimonotone and the time delays may appear in the reaction function as well as in the boundary function. Our approach to the problem is by the method of upper and lower solutions for nonquasimonotone functions.

To describe the system we consider a bounded domain \( \Omega \) in \( \mathbb{R}^n \) with boundary \( \partial \Omega \) and some positive constant vectors \( \tau \equiv (\tau_1, \ldots, \tau_N) \), \( \tau' \equiv (\tau'_1, \ldots, \tau'_N) \), representing the time delays. For any finite \( T > 0 \), we set

\[
D_T = (0, T], \quad S_T = (0, T] \times \partial \Omega, \quad \Omega_T = [0, T] \times \Omega, \quad Q_T = \Omega_T \times \cdots \times \Omega_T.
\]

©2001 American Mathematical Society
where $\bar{\Omega} = \Omega \cup \partial \Omega$ and $\tau_i = \max \{\tau_i, 1\}, \ i = 1, \cdots, N$. Denote by $C(\bar{\Omega})$ the set of continuous functions on $\bar{\Omega}$ and let $C(\bar{\Omega}) = C(\bar{\Omega}) \times \cdots \times C(\bar{\Omega})$ taken $N$-times. For any $u \equiv (u_1, \cdots, u_N)$ in $C(\bar{\Omega})$ we write

$$u_r \equiv u_r(t, x) \equiv (u_1(t - \tau_1 x), \cdots, u_N(t - \tau_N x)),$$

$$u_{r'} \equiv u_{r'}(t, x) \equiv (u_1(t - \tau'_1 x), \cdots, u_N(t - \tau'_N x)).$$

Then the system of time-delayed parabolic equations is given in the form

$$\frac{\partial u_i}{\partial t} - L_i u_i = f_i(t, x, u, u_r) \quad \text{in} \ D_T,$$

$$B_i u_i = g_i(t, x, u, u_r) \quad \text{on} \ S_T,$$

$$u_i(t, x) = \eta_i(t, x) \quad \text{in} \ Q_0^{(i)} \ (i = 1, \cdots, N),$$

where for each $i, L_i$ and $B_i$ are the (uniform) elliptic and boundary operators given by

$$L_i u_i = \sum_{j,k=1}^{n} a_{j,k}^{(i)}(t, x) \frac{\partial^2 u_i}{\partial x_j \partial x_k} + \sum_{j=1}^{n} b_j^{(i)}(t, x) \frac{\partial u_i}{\partial x_j} + c_i(t, x) u_i,$$

$$B_i u_i \equiv \partial u_i / \partial \nu + \beta_i^{(i)} u_i,$$

with $\partial / \partial \nu$ denoting the outward normal derivative on $\partial \Omega$. It is assumed that $\partial \Omega$ is of class $C^{1+\alpha}$, and for each $i$ the coefficients of $L_i$ and the first partial derivatives of $a_{j,k}^{(i)}$ are H"older continuous on $\overline{D_T}, c_i \leq 0$ and $\beta_i^{(i)} \geq 0$, and $\eta_i$ is H"older continuous in $Q_0^{(i)}$. The functions $f_i(t, x, \cdot), g_i(t, x, \cdot)$ and $\beta_i^{(i)}(t, x)$ are H"older continuous in their respective domains, and $f_i(\cdot, u, v)$ and $g_i(\cdot, u, v)$ satisfy the local Lipschitz condition (2.5) in Section 2. It is allowed that $L_i = 0$ (and no boundary condition for the corresponding $u_i$) for some or all $i$. This means that problem (1.1) may consist of a combination of ordinary and parabolic equations.

The purpose of this paper is to show the existence and uniqueness of a solution to (1.1) by the method of upper and lower solutions. This existence result is obtained without any quasimonotone condition on $f_i(\cdot, u, u_r)$ or on $g_i(\cdot, u, u_r)$. We also show that in the special case where $f_i$ and $g_i$ possess a quasimonotone nondecreasing property then there exist two sequences which converge monotonically from above and below, respectively, to the unique solution. These results are stated in Section 2, and proofs of these results are given in Section 3.

2. THE MAIN RESULTS

In addition to the general smoothness assumptions in the Introduction we need a pair of coupled upper and lower solutions which are defined in the following.

Definition 2.1. Two smooth functions $\tilde{u} = (\tilde{u}_1, \cdots, \tilde{u}_N)$ and $\tilde{u} = (\tilde{u}_1, \cdots, \tilde{u}_N)$ are called coupled upper and lower solutions of (1.1) if $\tilde{u} \geq \tilde{u}$ on $\overline{Q_T}$ and if for each $i = 1, \cdots, N$,

$$\frac{\partial \tilde{u}_i}{\partial t} - L_i \tilde{u}_i \geq f_i(t, x, u, v) \quad \text{for} \ (u, v) \in \mathcal{S} \times \mathcal{S}_1 \ \text{with} \ u_i = \tilde{u}_i,$$

$$\frac{\partial \tilde{u}_i}{\partial t} \geq g_i(t, x, u, v) \quad \text{for} \ (u, v) \in \mathcal{S} \times \mathcal{S}_2 \ \text{with} \ u_i = \tilde{u}_i,$$

$$\frac{\partial \tilde{u}_i}{\partial t} - L_i \tilde{u}_i \leq f_i(t, x, u, v) \quad \text{for} \ (u, v) \in \mathcal{S} \times \mathcal{S}_1 \ \text{with} \ u_i = \tilde{u}_i,$$

$$\frac{\partial \tilde{u}_i}{\partial t} \leq g_i(t, x, u, v) \quad \text{for} \ (u, v) \in \mathcal{S} \times \mathcal{S}_2 \ \text{with} \ u_i = \tilde{u}_i,$$

$$\tilde{u}_i(t, x) \geq \eta_i(t, x) \geq \tilde{u}_i(t, x) \quad \text{in} \ Q_0^{(i)}.$$
In the above definition inequality between vectors is in the component-wise sense, and the smoothness of \( \hat{u}, \hat{v} \) is in the sense that these functions are continuously differentiable to the order appearing in (1.1). The subsets \( S, S_1 \) and \( S_2 \) are given by

\[
S = \{ u \in C(Q_T); u \leq \hat{u} \leq \hat{u} \text{ on } \overline{Q}_T \},
\]

\[
S_1 = \{ v \in C(Q_T); u_\tau \leq v_\tau \leq \hat{u}_\tau \text{ on } D_T \},
\]

\[
S_2 = \{ v \in C(Q_T); u_\tau' \leq v_\tau' \leq \hat{u}_\tau' \text{ on } D_T \}.
\]

Notice that if the \( N \)-vector functions

\[
f(\cdot, u, v) \equiv (f_1(\cdot, u, v), \cdots, f_N(\cdot, u, v)),
\]

\[
g(\cdot, u, v) \equiv (g_1(\cdot, u, v), \cdots, g_N(\cdot, u, v))
\]

are quasimonotone nondecreasing in \( S \times S_1 \) and \( S \times S_2 \) respectively (that is, for each \( i = 1, \cdots, N \), \( f_i(\cdot, u, v) \) and \( g_i(\cdot, u, v) \) are nondecreasing with respect to all the components of \( u \) and \( v \) except \( u_i \)), then the inequalities for \( \hat{u} \) in (2.1) are reduced to

\[
\begin{align*}
\partial u_i / \partial t - L_i \hat{u}_i & \geq f_i(t, x, \hat{u}, \hat{u}_\tau) \quad \text{in } D_T, \\
\partial u_i / \partial v & \geq g_i(t, x, \hat{u}, \hat{u}_\tau) \quad \text{on } S_T, \\
\hat{u}_i(t, x) & \geq \eta_i(t, x) \quad \text{in } Q_i^{(i)} \quad (i = 1, \cdots, N),
\end{align*}
\]

and those for \( \hat{v} \) are reduced to (2.4) with all the inequalities reversed. Similar inequalities can be obtained if \( f(\cdot, u, v) \) and \( g(\cdot, u, v) \) are mixed quasimonotone functions (e.g., see [9, 10]). We assume that a pair of coupled upper and lower solutions \( \hat{u}, \hat{v} \) exist, and for each \( i = 1, \cdots, N \) there exist positive constants \( K_i, K'_i \) such that

\[
|f_i(t, x, u, v) - f_i(t, x, u', v')| \leq K_i(|u - u'| + |v - v'|)
\]

for \( (u, v), (u', v') \in S \times S_1 \),

\[
|g_i(t, x, u, v) - g_i(t, x, u', v')| \leq K'_i(|u - u'| + |v - v'|)
\]

for \( (u, v), (u', v') \in S \times S_2 \),

where \( |w| = |w_1| + \cdots + |w_N| \) for any \( w = (w_1, \cdots, w_N) \) in \( \mathbb{R}^N \). Our main existence-uniqueness result is the following.

**Theorem 2.1.** Let \( \hat{u}, \hat{v} \) be a pair of coupled upper and lower solutions of (1.1), and let condition (2.5) hold. Then there exists a unique solution \( u^* \equiv (u^*_1, \cdots, u^*_N) \in S \) to (1.1).

If the functions \( f(\cdot, u, v), g(\cdot, u, v) \) are quasimonotone nondecreasing, then for any initial iteration \( u^{(0)} \) we can construct a sequence \( \{ u^{(k)} \} \equiv \{ u^{(k)}_1, \cdots, u^{(k)}_N \} \) from the linear iteration process

\[
\begin{align*}
\mathcal{L}_i u^{(k)}_i = F_i(t, x, u^{(k-1)}_i) \quad & \text{in } D_T, \\
\mathcal{B}_i u^{(k)}_i = G_i(t, x, u^{(k-1)}_i) \quad & \text{on } S_T, \\
u^{(k)}_i(t, x) = \eta_i(t, x) \quad & \text{in } Q_i^{(i)} \quad (i = 1, \cdots, N),
\end{align*}
\]
where

\[ L_i u_i = \partial u_i / \partial t - L_i u_i + K_i u_i, \quad B_i u_i = B_i u_i + K'_i u_i, \]

\[ f_i(t, x, u, u_r) = K_i u_i + f_i(t, x, u, u_r), \quad G_i(t, x, u, u_r) = K'_i u_i + g_i(t, x, u, u_r) \]

\((i = 1, \ldots, N)\)

and \(K_i\) and \(K'_i\) are the Lipschitz constants in \((2.5)\). Denote the sequence by \(\{\mathbf{u}^{(k)}\}\) if \(u^{(0)} = \mathbf{u}\), and by \(\{\mathbf{u}^{(k)}\}\) if \(u^{(0)} = \mathbf{u}\). Then we have the following monotone convergence of these sequences.

**Theorem 2.2.** Let the conditions in Theorem 2.1 be satisfied. If, in addition, \(f(\cdot, u, v)\) and \(g(\cdot, u, v)\) are quasimonotone nondecreasing in \(S \times S_1\) and \(S \times S_2\), respectively, then the sequences \(\{\mathbf{u}^{(k)}\}\), \(\{\mathbf{u}^{(k)}\}\) converge monotonically to the unique solution \(u^* \in S\). Moreover,

\[ u^{(k)} \leq u^{(k+1)} \leq u^* \leq \mathbf{u}^{(k+1)} \leq \mathbf{u}^* \]

for every \(k = 1, 2, \ldots\).

**Remark 2.1.** Theorems 2.1 and 2.2 remain true if some of the boundary conditions in \((1.1)\) are replaced by the Dirichlet condition \(u_i = g_i(t, x)\). The proof for this case is the same as that given in Section 3 except with a slightly different integral representation from that in \((3.5)\) (see [8, 9, 11]).

As an application of the above theorems we consider a two-compartment model in generic repression which is given by (cf. [3, 11, 15])

\[
\begin{align*}
\frac{\partial u_1}{\partial t} + (a_1 + b_1)u_1 &= a_1 u_2 + f(v_1(t - \tau_1, x)), \\
\frac{\partial v_1}{\partial t} + (a_2 + b_2)v_1 &= a_2 v_2, \\
\frac{\partial u_2}{\partial t} - D_1 \nabla^2 u_2 + b_2 u_2 &= 0, \\
\frac{\partial v_2}{\partial t} - D_2 \nabla^2 v_2 + b_2 v_2 &= c_0 u_2(t - \tau_2, x) & \text{in } D_T, \\
\frac{\partial u_2}{\partial v} + \beta_2 u_2 &= \beta_2 v_1, \\
\frac{\partial v_2}{\partial v} + \beta_2 v_2 &= \beta_2 v_1 & \text{on } S_T, \\
u_1(0, x) &= \eta_1(0, x), \quad v_1(t, x) = \eta_1^*(t, x), & (\tau_1 \leq t \leq 0), \\
u_2(t, x) &= \eta_2(t, x), & (-\tau_2 \leq t \leq 0), \\
v_2(0, x) &= \eta_2^*(0, x),
\end{align*}
\]

where \(a_i, b_i, \beta_i\) and \(c_0, i = 1, 2\), are all positive constants. The function \(f(v_1)\) is given by \(f(v_1) = \sigma(1 + c_1 v_1^n)\) with \(\sigma\) and \(c_1\) being the kinetic constants and \(\rho \geq 1\) being the order of repression (cf. [6, 11]). It is easy to see by considering \((2.9)\) with \(u = (u_1, v_1, u_2, v_2)\) and \(L_1 = L_2 = 0\) that for any positive constants \(M, M^*\) satisfying

\[ M \geq \max\{\eta_1, \eta_2, \sigma/b_1\}, \quad M^* \geq \{\eta_1^*, \eta_2^*, c_0 M/b_2\}, \]

the pair \(\mathbf{u} = (M, M^*, M, M^*)\) and \(\mathbf{u} = (0, 0, 0, 0)\) are coupled upper and lower solutions. Since the Lipschitz condition \((2.5)\) is clearly satisfied by the functions at the right-hand side of \((2.9)\), Theorem 2.1 ensures that for any non-negative function \(\eta(t, x)\), problem \((2.9)\) has a unique bounded global solution \(u^* \equiv (u_1^*, v_1^*, u_2^*, v_2^*)\). A similar global existence result can be obtained for the three-compartment model in [6], including some improved upper and lower solutions which can be used to study the asymptotic behavior of the solution.
3. Proof of the theorems

To prove Theorem 2.1 we first consider an equivalent system of (1.1) given by
\begin{align}
\mathcal{L}_i u_i &= F_i(t, x, u, u_r) \quad \text{in } D_T, \\
\mathcal{B}_i u_i &= G_i(t, x, u, u_r) \quad \text{on } S_T, \\
\end{align}
(3.1)
\begin{align}
u_i(t, x) &= \eta_i(t, x) \quad \text{in } Q_0^{(i)} (i = 1, \ldots, N),
\end{align}
where $\mathcal{L}_i$, $\mathcal{B}_i$, $F_i$ and $G_i$ are given by (2.7). It is clear from (2.1) and (2.7) that
\begin{align}
\mathcal{L}_i \tilde{u}_i &\geq F_i(t, x, u, v) \quad \text{for } (u, v) \in \mathcal{S} \times \mathcal{S}_1 \text{ with } u_i = \tilde{u}_i,
\end{align}
(3.2)
\begin{align}
\mathcal{B}_i \tilde{u}_i &\geq G_i(t, x, u, v) \quad \text{for } (u, v) \in \mathcal{S} \times \mathcal{S}_2 \text{ with } u_i = \tilde{u}_i,
\end{align}
and a similar relation for $\hat{u}_i$. We show that problem (3.1) has a unique solution if $F_i(\cdot, u, v)$ and $G_i(\cdot, u, v)$ satisfy the following hypothesis.

**Hypothesis (H).** For each $i = 1, \ldots, N$, $F_i(t, x, u, v)$ and $G_i(t, x, u, v)$ are uniformly bounded on $\overline{D_T} \times \mathbb{R}^N$ and satisfy the global Lipschitz condition
\begin{align}
|F_i(t, x, u, v) - F_i(t, x, u', v')| &\leq K_i(|u - u'| + |v - v'|),
\end{align}
(3.3)
\begin{align}
|G_i(t, x, u, v) - G_i(t, x, u', v')| &\leq K_i(|u - u'| + |v - v'|)
\end{align}
for all $u, u', v, v'$ in $\mathbb{R}^N$.

Let $\Gamma_i(t, x; s, \xi)$ be the fundamental solution of $\mathcal{L}_i$, and let
\begin{align}
J^{(o)}_i(t, x) &\equiv \int_{\Omega} \Gamma_i(t, x; 0, \xi) \eta_i(0, \xi)d\xi,
\end{align}
(3.4)
\begin{align}
(F_i(u, u_r))(t, x) &\equiv F_i(t, x, u(t, x), u_r(t, x)),
\end{align}
\begin{align}
(G_i(u, u_r))(t, x) &\equiv G_i(t, x, u(t, x), u_r(t, x)) \quad (i = 1, \ldots, N),
\end{align}
where $u(t, x) = \eta(t, x)$ when $t \leq 0$ (cf. [8]). Define an operator $A_i : C(\overline{D_T}) \rightarrow C(\overline{D_T})$ by
\begin{align}
(A_i u)(t, x) &= J^{(o)}_i(t, x) + \int_{s}^{t} ds \int_{\Omega} \Gamma_i(t, x; s, \xi)(F_i(u, u_r))(s, \xi)d\xi
\end{align}
(3.5)
\begin{align}
&+ \int_{s}^{t} ds \int_{\partial \Omega} \Gamma_i(t, x; s, \xi) \psi_i(s, \xi)d\xi \quad (i = 1, \ldots, N),
\end{align}
where $\psi_i(t, x)$ is the density of the single layer potential and it is associated with the functions $F_i(u, u_r)$ and $G_i(u, u_r)$ (cf. [8], pg. 495). In the case $L_i = 0$, $A_i$ is defined by
\begin{align}
(A_i u)(t, x) &= \eta_i(0, x) + \int_{0}^{t} (F(u, u_r))(s, x)ds \quad (x \in \overline{\Omega}).
\end{align}
(3.6)

By the integral representation for parabolic boundary value problems a solution of (3.1), if it exists, may be expressed as
\begin{align}
u_i = A_i u \quad \text{on } \overline{D_T} \quad (i = 1, \ldots, N).
\end{align}
(3.7)
Define $A : B_r \rightarrow C(\overline{D_T})$ by
\begin{align}
Au = (A_1 u, \ldots, A_N u) \quad (u \in B_r),
\end{align}
where $B_r$ is the ball in $C(\overline{D_T})$ with radius $r > 0$. Then equation (3.7) has a unique solution in $B_r$ if $A$ has a unique fixed point in $B_r$. We show this in the following.
Lemma 3.1. Under the hypothesis (H) the integral system (3.7) has a unique solution \( u^* = (u^*_1, \cdots, u^*_N) \) in \( B_r \) for some \( r > 0 \). Moreover, \( u^* \) is the unique solution of (3.1).

Proof. By (3.5) and the positive property of \( \Gamma_i \),
\[
|A_i u| \leq |J_i^{(0)}| + \int_0^t \int_{\Omega} \Gamma_i(t, x; s, \xi) |F_i(u, u_\tau)| d\xi + \int_0^t \int_{\partial \Omega} \Gamma_i(t, x; s, \xi) |\psi_i(s, \xi)| d\xi.
\]
Since \( u_c \) and \( u_{\tau} \) are known when \( t \leq 0 \), Hypothesis (H) implies that \( F_i(u, u_\tau) \) and \( G_i(u, u_\tau) \) are uniformly bounded for all \( u, u_\tau \) and \( u_{\tau} \) in \( C(\overline{D}_T) \). By Lemma 9.6.1 of [4], \( \psi_i(t, x) \) is bounded and continuous on \( S_T \). In view of
\[
\int_0^t ds \int_{\Omega} \Gamma_i(t, x; s, \xi) d\xi + \int_0^t ds \int_{\partial \Omega} \Gamma_i(t, x; s, \xi) d\xi \leq C_i
\]
for some constant \( C_i \), the uniform boundedness of \( F_i(u, u_\tau) \) and \( \psi_i(t, x) \) ensures the existence of \( r_1 > 0 \) such that \( |A_i u| \leq r_1 \) for all \( u \in C(\overline{D}_T) \). It is obvious from (3.6) that this relation also holds if \( L_i = 0 \). By the definition of \( A \) we obtain \( \|A u\| \leq r \), where \( r = r_1 + \cdots + r_N \) and \( \|\cdot\| \) is the (maximum) norm in \( C(\overline{D}_T) \).

Let \( \psi_i^{(l)}(t, x) \) be the density function corresponding to \( F_i(u^{(l)}, u_\tau^{(l)}) \) and \( G_i(u^{(l)}, u_\tau^{(l)}) \), where \( l = 1, 2 \). By Lemma 9.6.1 of [4] there exists a constant \( K_i^* \) such that
\[
|\psi_i^{(1)}(t, x) - \psi_i^{(2)}(t, x)| \leq K_i^* \|u^{(1)} - u^{(2)}\|.
\]
Using this relation and the argument in the proof of Lemma 9.6.2 in [4], we conclude that \( A \) is a compact operator on \( B_r \) into itself. The existence of a fixed point \( u^* \in B_r \) follows from the Schauder fixed point theorem. Finally, by the argument in the proof of Theorem 9.6.1 in [4] \( u^* \) is a classical solution of (3.1).

To show the uniqueness of the solution we let \( \tau_o = \min\{\tau_1, \cdots, \tau_N, \tau_1', \cdots, \tau_N'\} \) and consider problem (3.7) in the domain \( D_1 = (0, \tau_o) \times \Omega \) (that is, with \( T = \tau_o \)). Since \( u_c \) and \( u_{\tau} \) are known in \( D_1 \), the argument in the proof of Theorem 9.6.1 in [4] shows that the solution \( u^* \) is unique on \( \overline{D}_1 = (0, \tau_o) \times \Omega \). Knowing the uniqueness of the solution in \( \overline{D}_1 \), a ladder argument ensures that \( u^* \) is the unique solution of (3.7) on \( \overline{D}_m = (0, m\tau_o) \times \Omega \) for every integer \( m = 1, 2, \cdots \). This proves the lemma. \( \square \)

Proof of Theorem 2.1. The proof is based on Lemma 3.1 for some modified functions \( \tilde{F}_i(\cdot, u, u_\tau) \) and \( \tilde{G}_i(\cdot, u, u_\tau) \) which are defined to coincide with \( F_i(\cdot, u, u_\tau) \) on \( S_1 \times S_1 \) and with \( G_i(\cdot, u, u_\tau) \) on \( S_1 \times S_2 \) and satisfy the conditions in Hypothesis (H). For example, if we denote by \( [u]_\sigma \) a vector in \( \mathbb{R}^\sigma \) with \( \sigma \) components of \( u \in \mathbb{R}^N \) and write \( u \) in the split form
\[
u = ([u]_{a_i}, [u]_{b_i}, [u]_{c_i}) \quad (i = 1, \cdots, N)
\]
for each \( i \), where \( a_i, b_i, \) and \( c_i \) are nonnegative integers satisfying \( a_i + b_i + c_i = N \) and
\[
[u]_{a_i} > [u]_{a_i}, \quad [u]_{b_i} \geq [u]_{b_i}, \quad [u]_{c_i} < [u]_{c_i},
\]
Then a possible choice of \( \tilde{F}_i, \tilde{G}_i \) are the truncated functions given by
\[
\tilde{F}_i(\cdot, u, \mu, r) = F_i(\tilde{u}_i a_i, [u] b_i, [u] c_i, [\tilde{u}_i] a_i, [u] b_i, [\tilde{u}_i] c_i),
\]
\[
\tilde{G}_i(\cdot, u, \mu, r) = G_i(\tilde{u}_i a_i, [u] b_i, [u] c_i, [\tilde{u}_i] a_i, [u] b_i, [\tilde{u}_i] c_i),
\]
where \( a_i, b_i \) and \( c_i \) may be different for different \( u \). In other words, the modified functions \( \tilde{F}_i, \tilde{G}_i \) are obtained from \( F_i \) and \( G_i \) by replacing the component \( u_j \) by \( \tilde{u}_j \) whenever \( u_j > \tilde{u}_j \), and by \( \tilde{u}_j \) whenever \( u_j < \tilde{u}_j \). Hence the integer \( a_i \) (resp., \( c_i \)) in the split form of \( u \) is the maximal number of components \( u_j \) satisfying \( u_j > \tilde{u}_j \) (resp., \( u_j < \tilde{u}_j \)). The above definition implies that the truncated functions \( \tilde{F}_i \) and \( \tilde{G}_i \) satisfy the conditions in Hypothesis (H). By Lemma 3.1 the modified problem of (3.1) (that is, problem (3.1) with \( \tilde{F}_i, \tilde{G}_i \) replaced, respectively, by \( \tilde{F}_i \) and \( \tilde{G}_i \)) has a unique solution \( u^* \). Hence to prove the theorem it suffices to show \( \tilde{u} \leq u^* \leq \tilde{u} \) on \( T \).

Given any \( u \in \mathbb{R}^N \) we write \( u = (u_i, [u]_{N-1}) \). By the Lipschitz condition (2.5),
\[
K_i \tilde{u}_i + f_i(\cdot, \tilde{u}_i, [u]_{N-1}, \mu) \leq K_i u_i + f_i(\cdot, u_i, [u]_{N-1}, \mu) \leq K_i \tilde{u}_i + f_i(\cdot, \tilde{u}_i, [u]_{N-1}, \mu) \quad \text{for} \quad (u, \mu, r) \in S \times S_1.
\]
This implies that the truncated function \( \tilde{F}_i \) satisfies the relation
\[
\tilde{F}_i(\tilde{u}_i, [u]_{N-1}, \mu, r) \leq \tilde{F}_i(u_i, [u]_{N-1}, \mu, r) \leq \tilde{F}_i(\tilde{u}_i, [u]_{N-1}, \mu, r) \quad \text{for all} \quad u, \mu, r \in \mathbb{R}^N.
\]
A similar relation holds for \( \tilde{G}_i(u_i, [u]_{N-1}, \mu, r) \). These relations and (3.2) yield
\[
\mathcal{L}_i \tilde{u}_i \geq \tilde{F}_i(u, \mu, r) \quad \text{in} \quad DT,
\]
\[
B_i \tilde{u}_i \geq \tilde{G}_i(u, \mu, r) \quad \text{on} \quad ST
\]
for all \( u, \mu, r \) in \( \mathbb{R}^N \). Similarly, \( \tilde{u}_i \) satisfies the inequalities in (3.11) in reversed order. Since \( u^* \) satisfies (3.1) when \( \tilde{F}_i \) and \( \tilde{G}_i \) are replaced by \( \tilde{F}_i \) and \( \tilde{G}_i \) we see from (3.11) that the function \( w_i = \tilde{u}_i - u^*_i \) satisfies the relation
\[
\mathcal{L}_i w_i = \mathcal{L}_i \tilde{u}_i - \tilde{F}_i(u, \mu, r) \geq 0 \quad \text{in} \quad DT,
\]
\[
B_i w_i = B_i \tilde{u}_i - \tilde{G}_i(u, \mu, r) \geq 0 \quad \text{on} \quad ST,
\]
\[
w_i(0, x) = \tilde{u}_i(0, x) - \eta_i(0, x) \geq 0 \quad \text{in} \quad \Omega \quad (i = 1, \ldots, N).
\]
By the positivity lemma for parabolic boundary value problems we obtain \( w_i \geq 0 \) on \( \overline{T}, i = 1, \ldots, N \). This proves \( u^* \leq \tilde{u} \). A similar argument gives \( u^* \geq \tilde{u} \). This shows that \( u^* \) is the unique solution of the original problem (3.1). The equivalence between (3.1) and (1.1) ensures that \( u^* \) is the unique solution of (1.1) in \( S \). This completes the proof of the theorem. \( \square \)

**Proof of Theorem 2.2.** It is easily seen from the argument in [8] (see pg. 494) for parabolic boundary value problems without time delays that the sequences \( \{\tilde{u}^k\}, \{u^k\} \) governed by (2.6) with \( \tilde{u}^{(0)} = \tilde{u} \) and \( \tilde{u}^{(0)} = \tilde{u} \), respectively, possess the monotone property in (2.8). This implies that the pointwise limits
\[
\lim_{k \to \infty} \tilde{u}^{(k)}(t, x) = \tilde{u}(t, x), \quad \lim_{k \to \infty} u^{(k)}(t, x) = \bar{u}(t, x)
\]
exist and satisfy relation (2.8) where $u^*$ is replaced by $\mathbf{u}$ or $\mathbf{u}$. Since by (3.5)–(3.6) the sequence $\{u^{(k)}\}$ given in (2.6) can be expressed as

$$u^{(k)}_i = A_i u^{(k-1)}_i, \quad k = 1, 2, \ldots \quad (i = 1, \ldots, N),$$

the dominated convergence theorem ensures that $u_i = A_i u_i, \quad i = 1, \ldots, N$, where $u$ stands for either $\mathbf{u}$ or $\mathbf{u}$. A regularity argument as that in $\mathbf{3}$ shows that $\mathbf{u}$ and $\mathbf{u}$ are solutions of (3.1). Finally, a ladder argument as that in the proof of Lemma 3.1 shows that $\mathbf{u} = \mathbf{u}$ and their common value is the unique solution of (1.1) in $\mathcal{S}$. $\blacksquare$
