ULTRASTABILITY OF IDEALS OF HOMOGENEOUS POLYNOMIALS AND MULTILINEAR MAPPINGS ON BANACH SPACES

KLAUS FLORET AND STEPHAN HUNFELD

(Communicated by Dale Alspach)

Abstract. Using the theory of full and symmetric tensor norms on normed spaces, a theorem of Kursten and Heinrich on ultrastability and maximality of normed operator ideals is extended to ideals of \( n \)-homogeneous polynomials and \( n \)-linear mappings—scalar-valued and vector-valued. The motivation for these results is the following important special case: the “uniterated” Aron-Berner extension \( \mathcal{U} \) of an \( n \)-homogeneous polynomial \( q : E \to F \) to the bidual remains in certain ideals under preservation of the norm. Moreover, Lotz’s characterization of maximal normed ideals of linear mappings through appropriate tensor norms is proved for ideals of \( n \)-homogeneous scalar-valued polynomials and ideals of \( n \)-linear mappings.

1. Preliminaries

1.1. For vector spaces \( E_1, \ldots, E_n, E, F \) over \( \mathbb{K} = \mathbb{R} \) or \( \mathbb{C} \) the “full” \( n \)-fold tensor product of \( (E_1, \ldots, E_n) \) will be denoted by \( E_1 \otimes \cdots \otimes E_n = \otimes_{j=1}^n E_j \). The universal definition of the \( n \)-fold tensor product identifies the \( n \)-linear mappings \( E_1 \times \cdots \times E_n \to F \) with the linear mappings \( \otimes_{j=1}^n E_j \to F \):

\[ L(E_1, \ldots, E_n; F) = L(\otimes_{j=1}^n E_j; F), \quad \varphi \mapsto \varphi^L. \]

Symmetric linear mappings \( E^n \to F \) are linearized by the \( n \)-th symmetric tensor product \( \otimes^{n,s} E \):

\[ L_s(^n E; F) = L(\otimes^{n,s} E; F), \quad \varphi \mapsto \varphi^{L,s} \]

(see e.g. [F1] for more details). A mapping \( q : E \to F \) is, by definition, an \( n \)-homogeneous polynomial (notation: \( q \in P^n(E; F) \)) if there is a \( \varphi \in L(^n E; F) \) with \( q(x) = \varphi(x, \ldots, x) \) for all \( x \in E \). Actually there is a unique \( \tilde{q} \in L_s(^n E; F) \) with this property:

\[ P^n(E; F) = L_s(^n E; F) = L(\otimes^{n,s} E; F), \quad q \mapsto \tilde{q} \mapsto q^L. \]

If the spaces are normed, then the continuous \( n \)-linear mappings and \( n \)-homogeneous polynomials are denoted by \( \mathcal{L}(E_1, \ldots, E_n; F) \), \( \mathcal{L}_s(^n E; F) \) or \( \mathcal{P}^n(E; F) \), respectively.

1.2. Again for fixed $n \in \mathbb{N}$ the projective norm $\pi$ is uniquely defined by the property

$$ [\otimes_\pi(E_1, \ldots, E_n)'] \overset{1}{=} \mathcal{L}(E_1, \ldots, E_n) := \mathcal{L}(E_1, \ldots, E_n; \mathbb{K}) $$

if $E_1, \ldots, E_n$ are normed spaces ($\overset{1}{=} \text{ means isometrically equal}$).

The injective norm $\varepsilon$ satisfies, by definition ($\overset{1}{\rightarrow}$ stands for a metric injection),

$$ \otimes_\varepsilon(E_1, \ldots, E_n) \overset{1}{\rightarrow} (\otimes_\pi(E_1, \ldots, E_n))' $$

this shows that $\varepsilon$ is somehow dual to $\pi$. A tensor norm $\beta$ of order $n$ assigns to each $n$-tuple $(E_1, \ldots, E_n)$ a norm $\beta(\cdot; E_1, \ldots, E_n)$ on $\otimes(E_1, \ldots, E_n)$ (notation: $\otimes_\beta(E_1, \ldots, E_n)$ or $\otimes_{\beta,j=1}^n E_j$) such that

(a) $\varepsilon \leq \beta \leq \pi$,

(b) $\|\otimes_{\beta,j=1}^n T_j \cdot \otimes_{\beta,j=1}^n E_j \rightarrow \otimes_{\beta,j=1}^n F_j \| \leq \prod_{j=1}^n \| T_j : E_j \rightarrow F_j \|$ for all operators $T_j \in \mathcal{L}(E_j; F_j)$ (the metric mapping property).

Note that (a) and (b) imply that in (b) there is actually equality. $\beta$ is called finitely generated if for all $E_j$ and $z \in \otimes_{\beta,j=1}^n E_j$

$$ \beta(z; E_1, \ldots, E_n) = \inf \{ \beta(z; M_1, \ldots, M_n) \mid M_j \in \text{FIN}(E_j), z \in \otimes_{\beta,j=1}^n M_j \} $$

(where FIN($E_j$) denotes the set of finite-dimensional subspaces of $E_j$). $\varepsilon$ and $\pi$ are finitely generated tensor norms of order $n$. There is no general reference for the theory of tensor norms of order $n > 2$; many results, however, are straightforward generalizations of the case $n = 2$ which, e.g., is treated in [DF].

1.3. In the same spirit the natural projective and injective norms $\pi_s$ and $\varepsilon_s$ on the $n$-th symmetric tensor product satisfy

$$ (\otimes_{\pi_s}^n E)' \overset{1}{=} \mathcal{P}^n(E; \mathbb{K}) =: \mathcal{P}(E), $$

$$ \otimes_{\varepsilon_s}^n E \overset{1}{\rightarrow} \mathcal{P}(E'). $$

An $s$-tensor norm $\alpha$ of order $n$ (or shortly $s$-tensor norm, if $n \in \mathbb{N}$ is clear) assigns to each normed space $E$ a norm $\alpha(\cdot; \otimes_{\alpha}^n E)$ on $\otimes_{\alpha}^n E$ (notation: $\otimes_{\alpha}^n E$) such that

(a) $\varepsilon_s \leq \alpha \leq \pi_s$,

(b) the metric mapping property $\| \otimes_{\alpha}^n T : \otimes_{\alpha}^n E \rightarrow \otimes_{\alpha}^n F \| \leq \| T : E \rightarrow F \|^n$

for all $T \in \mathcal{L}(E; F)$.

$\alpha$ is called finitely generated if for all $E$ and $z \in \otimes_{\alpha}^n E$,

$$ \alpha(z; \otimes_{\alpha}^n E) = \inf \{ \alpha(z; \otimes_{\alpha}^n M) \mid M \in \text{FIN}(E), z \in \otimes_{\alpha}^n M \}. $$

A detailed study of $\varepsilon_s$ and $\pi_s$ can be found in [F1]; the theory of $s$-tensor norms (in the spirit of Grothendieck’s theory of tensor norms of order 2, see [DF]) will be developed in a forthcoming paper [F2]. We do not need anything from the general theory in this paper. Note that for convenience the definitions allow $n$ to be 1: in this case $\otimes_1^1 E \overset{1}{=} E \overset{1}{=} \otimes_{\alpha}^1 E$.

1.4. Let $\mathcal{U}$ be an ultrafilter on a set $I$; the ultraproduct (along $\mathcal{U}$) of a family $(E_i)_{i \in I}$ of Banach spaces $E_i$ will be denoted by $(E_i)_\mathcal{U}$ (see e.g. [DF] 18.4). Now take $\varphi_i \in \mathcal{L}(E_{1,i}, \ldots, E_{n,i}; F_i)$ for all $i \in I$ such that sup$_{i \in I} \| \varphi_i \| < \infty$. Then

$$ \left( \varphi_i \right)_\mathcal{U}(x_i^1, \ldots, x_i^n) := \left( \varphi_i(x_i^1, \ldots, x_i^n) \right)_\mathcal{U} $$
defines an $n$-linear map $(E_{i,t})_{\mathfrak{U}} \times \cdots \times (E_{n,t})_{\mathfrak{U}} \rightarrow (F_i)_{\mathfrak{U}}$ between the ultraproducts; it easily follows that $\|\varphi\|_{\mathfrak{U}} = \lim_{\mathfrak{U}} \|\varphi_i\|$. If $F_i = \mathbb{K}_m$, then

$$\overline{(\varphi_i)}_{\mathfrak{U}}((x_1^n)_{\mathfrak{U}}, \ldots, (x_n^n)_{\mathfrak{U}}) = \lim_{\mathfrak{U}} \varphi_i(x_1, \ldots, x_n)$$

since $(\mathbb{K}_m)_{\mathfrak{U}} = \mathbb{K}_m$; in this case we write $\lim_{\mathfrak{U}} \varphi_i$ for $\overline{(\varphi_i)}_{\mathfrak{U}}$. If $E_{1,t} = \cdots = E_{n,t} = E_t$, it is clear that $(\varphi_i)_{\mathfrak{U}}$ is symmetric if all $\varphi_i$ are; in particular, for polynomials $q_i \in \mathcal{P}^n(E_i; F_i)$ with $\sup_{x} \|q_i\| < \infty$, $$(q_i)_{\mathfrak{U}}((x_1)_{\mathfrak{U}}, \ldots, (x_n)_{\mathfrak{U}})$$
is an $n$-homogeneous polynomial $(E_{i,t})_{\mathfrak{U}} \rightarrow (F_i)_{\mathfrak{U}}$. Again it is rather immediate to see that

$$(\mathcal{P}^n(E_i; F_i))_{\mathfrak{U}} \rightarrow \mathcal{P}^n((E_i)_{\mathfrak{U}}; (F_i)_{\mathfrak{U}}), \quad (q_i)_{\mathfrak{U}} \rightarrow (q_i)_{\mathfrak{U}}$$
is an isometry; for $F_i = \mathbb{K}_m$ we write $\lim_{\mathfrak{U}} q_i := (q_i)_{\mathfrak{U}}$. The purpose of this paper is to study under which circumstances $(q_i)_{\mathfrak{U}}$ (resp. $(\varphi_i)_{\mathfrak{U}}$) is in a certain class of polynomials (resp. $n$-linear mappings) if all $q_i$ (resp. $\varphi_i$) are.

1.5. For this, two special properties of ultraproducts will be needed: local determination and local duality.

**Proposition** (local determination of ultraproducts). Let $E_i$ be normed spaces for $i \in I$ and $\{0\} \neq M \in \text{FIN}((E_{i,t})_{\mathfrak{U}})$. Then there are, for all $i \in I$, operators $R_i \in \mathcal{L}(M; E_i)$ such that

- (a) $x = (R_i x)_t$ for all $x \in M$;
- (b) $\|R_i\| \leq 1$ for all $i \in I$ and there is an $\mathfrak{U} \in \mathfrak{U}$ with $\|R_i\| = 1$ for all $i \in \mathfrak{U}$;
- (c) for all $\varepsilon > 0$ there is an $\mathfrak{U}_\varepsilon \in \mathfrak{U}$ such that the inverse $R_i^{-1} : R_i(M) \rightarrow M$ exists and $\|R_i^{-1}\| \leq 1 + \varepsilon$ for all $i \in \mathfrak{U}_\varepsilon$.

This is due to Kürsten [K Satz 4.1] and Heinrich [H Prop. 6.1]. Here we shall only need (a) and the first part of (b).

1.6. For the local duality, take normed spaces $E_i$ and denote by

$$J : (E_i')_{\mathfrak{U}} \rightarrow (E_i)_{\mathfrak{U}}', \quad J(x'_i)_t = \lim_{\mathfrak{U}} x'_i$$

the natural map from 1.4., i.e., $\langle J(x'_i)_t, (x_i)_{\mathfrak{U}} \rangle = \lim_{\mathfrak{U}} \langle x'_i, x_i \rangle$, and by

$$K : (E_i)_{\mathfrak{U}} \mapsto (E_i)''_{\mathfrak{U}} \xrightarrow{J'} (E'_i)_{\mathfrak{U}}.$$**Proposition** (local duality of ultraproducts). Let $E_i$ be normed spaces for all $i \in I$, $N \in \text{FIN}((E_i')_{\mathfrak{U}})$ and $L \in \text{FIN}((E_i)_{\mathfrak{U}})$. Then for every $\varepsilon > 0$ there is an operator $T \in \mathcal{L}(N; (E_i)_{\mathfrak{U}})$ such that

- (a) $\|T\| = 1$ and $\|T^{-1} : TN \rightarrow N\| \leq 1 + \varepsilon$,
- (b) $JT x' = x'$ for all $x' \in N \cap \text{im } J$,
- (c) $\langle JT x', x \rangle = \langle K x, T x' \rangle = \langle x', x \rangle$ for all $x' \in N$ and $x \in L$.

This result is due to Kürsten [K], Stern (see [H for references]) and Heinrich [H]; the present formulation is taken from the proof of [H Theorem 7.3]. We shall only need $\|T\| = 1$ and (c).
2. The main theorem on ultrastability

2.1. Every $z' \in \left(\bigotimes_{k=1}^{m}(\bigotimes_{n_k}^{E_k})\right)'$ defines a $(\sum_{k=1}^{m}n_k)$-linear functional $\varphi$ on $\prod_{k=1}^{m}(E_k)^{n_k}$ which is symmetric in the $n_k$ variables in $E_k$ for each $k = 1, \ldots, m$, and vice-versa. In the spirit of the notations of 1.1 we may define $\varphi^L := z'$. For ultraproducts and $z' = \varphi^L$ the notation

$$\lim_{\mathcal{U}} z' := \left[\lim_{\mathcal{U}} \varphi^L\right]$$

will be used in the following:

**Theorem.** Let $m, n_1, \ldots, n_m \in \mathbb{N}$, $\mathcal{U}$ an ultrafilter on $I$, normed spaces $E_{k,i}$, a finitely generated tensor norm $\beta$ of order $m$ and finitely generated $s$-tensor norms $\alpha_k$ of order $n_k$ be given. If $z' \in \left(\bigotimes_{k=1}^{m}(\bigotimes_{n_k}^{E_{k,i}})\right)' =: H$, for all $i \in I$ such that $\sup_{k \in I} \|z'\|_{H_k} < \infty$, then

$$\lim_{\mathcal{U}} z' \in \left[\bigotimes_{k=1}^{m}(\bigotimes_{n_k}^{E_{k,i}})\right]' =: H$$

and $\|\lim_{\mathcal{U}} z'\|_H \leq \lim_{\mathcal{U}} \|z'\|_H$.

**Proof.** Since $\beta$ and all $\alpha_k$ are finitely generated, it is enough to show that for all $M_k \in \text{FIN}(E_{k,i} \mathcal{U})$ and all $z \in \bigotimes_{k=1}^{m}(\bigotimes_{n_k}^{E_{k,i}})M_k =: M$,

$$|\lim_{\mathcal{U}} z' \cdot z| \leq \lim_{\mathcal{U}} \|z'\|_H \cdot \beta(z; \bigotimes_{\alpha_1}^{n_1}M_1, \ldots, \bigotimes_{\alpha_m}^{n_m}M_m)$$

holds. Given these $M_k$ the local determination of ultraproducts (see 1.5) gives operators $R_{k,i} : M_k \rightarrow E_{k,i}$ with $\|R_{k,i}\| \leq 1$ and $(R_{k,i}x_k)_{\mathcal{U}} = x_k$ for all $x_k \in M_k$; it follows that

$$\left\langle \lim_{\mathcal{U}} z', \left[\bigotimes_{k=1}^{m}x_1 \otimes \cdots \otimes \bigotimes_{k=1}^{m}x_m\right] \right\rangle_{=R_{k,i}} = \left\langle \lim_{\mathcal{U}} z', \left[\bigotimes_{k=1}^{m}(R_{1,i}x_1)_{\mathcal{U}} \otimes \cdots \otimes \bigotimes_{k=1}^{m}(R_{m,i}x_m)_{\mathcal{U}}\right]\right\rangle_{=R_{k,i}}$$

and hence for all $z \in M$,

$$|\lim_{\mathcal{U}} z' \cdot z| = |\lim_{\mathcal{U}} \langle z', R_{k,i}z \rangle|$$

$$\leq \|\lim_{\mathcal{U}} z'\|_H \beta(z; \bigotimes_{\alpha_1}^{n_1}E_{1,i}, \ldots, \bigotimes_{\alpha_m}^{n_m}E_{m,i})$$

$$\leq \|\lim_{\mathcal{U}} z'\|_H \|R_{1,i}\| \cdots \|R_{m,i}\| \beta(z; \bigotimes_{\alpha_1}^{n_1}M_1, \ldots, \bigotimes_{\alpha_m}^{n_m}M_m)$$

by the metric mapping properties of $\beta$ and $\alpha_1, \ldots, \alpha_m$. This is the desired inequality. \hfill \Box

In other words, the natural map

$$\left(\bigotimes_{k=1}^{m}(\bigotimes_{n_k}^{E_{k,i}})\right)'_{\mathcal{U}} \rightarrow \left[\bigotimes_{k=1}^{m}(\bigotimes_{n_k}^{E_{k,i}})\right]'_{\mathcal{U}}$$

has norm $\leq 1$. It is rather immediate that the norm is 1 if all $E_i \neq \{0\}$ and that for $\beta = \pi$ and $\alpha_k = \pi_s$ this is even an isometry (as in the special cases of 1.4, one has to take $x_{k,i} \in B_{E_{k,i}}$ with $\langle x_i', \ldots \rangle \geq \|x_i'\|(1 - c)$).
2.2. Note the special cases of \( m = 1 \) (polynomials) and all \( n_k = 1 \) (no symmetry):
(a) If \( \alpha \) is a finitely generated \( s \)-tensor norm of order \( n \), then for all normed spaces \( E_i \) the natural map
\[
\left( \otimes^{n,s}_{\alpha} E_i \right)'_U 
\to \left( \otimes^{n,s}_{\alpha} (E_i)_U \right)'
\]
has norm \( \leq 1 \).
(b) If \( \beta \) is a finitely generated tensor norm of order \( m \), then for all normed spaces \( E_{k,i} \) the natural map
\[
\left( \left( \otimes_{\beta} (E_{1,i}, \ldots, E_{m,i}) \right)'ight)_U 
\to \left( \otimes_{\beta} ((E_{1,i})_U, \ldots, (E_{m,i})_U) \right)'
\]
has norm \( \leq 1 \).

2.3. It is clear that the same reasoning gives that the natural map
\[
\left( \left[ \otimes_{\alpha}^{m,s} \left( \otimes_{\beta,k=1}^{n} E_{k,i} \right) \right] \right)'_U 
\to \left[ \otimes_{\alpha}^{m,s} \left( \otimes_{\beta,k=1}^{n} (E_{k,i})_U \right) \right]'
\]
has norm \( \leq 1 \).

3. Scalar-valued ideals of polynomials and multilinear mappings

3.1. A subclass \( Q \subset \mathcal{P}^n \) of \( n \)-homogeneous continuous scalar-valued polynomials on Banach spaces is called an ideal if
(a) \( Q(E) := \mathcal{P}^n(E) \cap Q \) is a linear subspace of \( \mathcal{P}^n(E) \) for all Banach spaces \( E \),
(b) if \( T \in \mathcal{L}(E; F) \) and \( q \in \mathcal{Q}(F) \), then \( q \circ T \in \mathcal{Q} \),
(c) \( [K \ni z \mapsto z^n \in K] \in \mathcal{Q} \).
If \( \| \cdot \|_Q : \mathcal{Q} \to [0, \infty] \) satisfies
(a') \( \| \cdot \|_Q \mid_{Q(E)} \) is a norm for all Banach spaces \( E \),
(b') \( \|q \circ T\|_Q \leq \|T\|_n \|q\|_Q \) in the situation of (b),
(c') \( [K \ni z \mapsto z^n \in K]\|_Q = 1 \),
then \((\mathcal{Q}, \| \cdot \|_Q)\) is called a normed ideal of \( n \)-homogeneous polynomials. It can easily be seen that always \( \|q\| \leq \|q\|_Q \) and that \( \mathcal{Q}(M) = \mathcal{P}^n(M) = \otimes^{n,s} M' \) for all finite-dimensional \( M \). It would also be possible to define ideals of polynomials on normed spaces (not only Banach spaces) – but this would not make much of a difference.

It is rather immediate to see that for each \( s \)-tensor norm \( \alpha \) of order \( n \)
\[
Q(E) := (\otimes^{n,s}_\alpha E)' \]
defines a normed ideal of \( n \)-homogeneous polynomials. For \( \alpha = \varepsilon_s \) one obtains the integral polynomials (see e.g. [FT] chap. 3 for their properties). It is not difficult to see that all extendible \( n \)-homogeneous polynomials (i.e., those \( q \in \mathcal{P}^n(E) \) such that for all super spaces \( G \supseteq E \) there is an extension \( \tilde{q} \in \mathcal{P}^n(G) \) of \( G \); see Kirwan and Ryan [KR]) are also of this form; in this case the \( s \)-tensor norm \( \alpha \) of order \( n \) is the “injective associate” of the projective \( s \)-norm \( \pi_s \), i.e., satisfies
\[
\otimes^{n,s}_\alpha E \to \otimes^{n,s}_{\pi_s} \ell_\infty(B_{E'}) ;
\]
we omit the details.
3.2. For \((\mathcal{Q}, \| \cdot \|_{\mathcal{Q}})\) and \(q \in \mathcal{P}^n(E)\) define
\[
\|q\|_{\mathcal{Q}_{\text{max}}} := \sup\{\|q|_M\|_{\mathcal{Q}} \mid M \in \text{FIN}(E)\} \in [0, \infty].
\]
\((\mathcal{Q}, \| \cdot \|_{\mathcal{Q}})\) is called \textit{maximal} if every \(q \in \mathcal{P}^n(E)\) with \(\|q\|_{\mathcal{Q}_{\text{max}}} < \infty\) is in \(\mathcal{Q}\) and \(\|q\|_{\mathcal{Q}} = \|q\|_{\mathcal{Q}_{\text{max}}}\). \((\mathcal{Q}, \| \cdot \|_{\mathcal{Q}})\) is called \textit{ultrastable} if for \(q_\nu \in \mathcal{Q}(E_\nu)\) with \(\sup_{\nu \in I} \|q_\nu\|_{\mathcal{Q}} < \infty\) one has \(\lim_{\nu} q_\nu \in \mathcal{Q}(E)\) and \(\lim_{\nu} q_\nu \|_{\mathcal{Q}} \leq \|q\|_{\mathcal{Q}}\) (and hence \(\leq \lim_{\nu} \|q_\nu\|_{\mathcal{Q}}\)).

**Theorem.** For each normed ideal \((\mathcal{Q}, \| \cdot \|_{\mathcal{Q}})\) of \(n\)-homogeneous (scalar-valued) polynomials the following statements are equivalent:

1. \((\mathcal{Q}, \| \cdot \|_{\mathcal{Q}})\) is maximal.
2. \((\mathcal{Q}, \| \cdot \|_{\mathcal{Q}})\) is ultrastable.
3. There is a finitely generated \(s\)-tensor norm \(\alpha\) of order \(n\) such that
\[
\mathcal{Q}(E) \overset{1}{=} (\otimes_{\alpha}^n E)'\]
for all Banach spaces \(E\).

It is clear that this result can be conjectured when knowing the Kürsten-Heinrich characterization of maximal Banach operator ideals [H Theorem 8.1] and Lotz’ representation with tensor norms of order 2 (see [DF 17.5]). It follows from (3) that \(\mathcal{Q}(E)\) is a Banach space if \(\mathcal{Q}\) is maximal.

**Proof.** (1) \(\supseteq\) (3). For finite-dimensional Banach spaces \(M\) define \(\alpha\) by
\[
\otimes_{\alpha}^n M := \mathcal{Q}(M)'
\]
and for arbitrary normed spaces \(E\) by
\[
\alpha(z; \otimes_{\alpha}^n E) := \inf \{\alpha(z; \otimes_{\alpha}^n M) \mid M \in \text{FIN}(E), \; z \in \otimes_{\alpha}^n M\}.
\]
It is straightforward to see that \(\alpha\) is a finitely generated \(s\)-tensor norm of order \(n\) with \((*)\) \(\mathcal{Q}(M) \overset{1}{=} (\otimes_{\alpha}^n E)'\) if \(M\) is finite-dimensional. Now
\[
\|q_L\|_{(\otimes_{\alpha}^n E)'} = \sup\{|(q_L, z)\mid \alpha(z; \otimes_{\alpha}^n E) < 1\}
\]
\[
= \sup\{|(q|_M L, z)\mid M \in \text{FIN}(E), \; z \in \otimes_{\alpha}^n M, \; \alpha(z; \otimes_{\alpha}^n M) < 1\}
\]
\[
\overset{(\ast)}{=} \sup\{\|q|_M\|_{\mathcal{Q}} \mid M \in \text{FIN}(E)\} = \|q\|_{\mathcal{Q}}
\]
by the maximality of \(\mathcal{Q}\).

(3) \(\supseteq\) (2). This is the special case 2.2(a) of the main theorem.

(2) \(\supseteq\) (1). Let \(q \in \mathcal{P}^n(E)\) with \(\|q\|_{\mathcal{Q}_{\text{max}}} < \infty\) and let \(\mathcal{U}\) be an ultrafilter finer than the order filter in \(\text{FIN}(E)\). For \(q|_M\) on \(M \in \text{FIN}(E)\) one obtains \(\|q|_M\|_{\mathcal{Q}} \leq \|q\|_{\mathcal{Q}_{\text{max}}}\) and \(\lim_{\mathcal{U}} q|_M : (M)_\mathcal{U} \rightarrow \mathbb{K}\) extends \(q\) (via the natural isometric embedding \(E \hookrightarrow (M)_\mathcal{U}\)). If follows from (2) that \(q \in \mathcal{Q}\) and
\[
\|q\|_{\mathcal{Q}} \leq \|\lim_{\mathcal{U}} q|_M\|_{\mathcal{Q}} \leq \sup\{\|q|_M\|_{\mathcal{Q}} \mid M \in \text{FIN}(E)\} = \|q\|_{\mathcal{Q}_{\text{max}}}
\]
and hence \(\|q\|_{\mathcal{Q}} = \sup\|q|_M\|_{\mathcal{Q}}\) since always \(\cdot \|_{\mathcal{Q}_{\text{max}}} \leq \| \cdot \|_{\mathcal{Q}}\).
3.3. Every \( q \in \mathcal{P}^n(E) \) has an extension to \( \mathcal{P}^n(E'') \): the Aron-Berner extension (see [AH]) can easily be seen as an iterated limit along local ultrafilters of \( E \) (see [LR] or [F1 6.9]). This motivated Dineen and Timoney [DT] and Lindström and Ryan [AB] to independently define an “uniterated” Aron-Berner extension (as it is called in [F1]) as follows: for \( i := (M, N, \varepsilon) \in I := \text{FIN}(E'') \times \text{FIN}(E') \times [0, 1] \) choose with the strong principle of local reflexivity an operator \( T_i \in \mathcal{L}(M; E) \) with \( T_i x = x \) for all \( x \in M \cap E \) such that \( \|T_i\| \leq 1 + \varepsilon \) and \( \langle T_i x'', x' \rangle \) for all \( (x'', x') \in M \times N \); for \( x'' \in E'' \) define \( f_i(x'') := T_i x'' \) if \( x'' \in M \) and \( f_i(x'') := 0 \) otherwise. Take a local ultrafilter \( \mathcal{U} \) on \( I \), i.e., an ultrafilter which is finer than the order filter on \( I \), then the natural mappings

\[
J_E : E'' \longrightarrow (E)_{\mathcal{U}}; \quad x'' \rightsquigarrow (f_i(x''))_{\mathcal{U}},
\]

\[
Q_E : (E)_{\mathcal{U}} \longrightarrow E''; \quad (x_i)_{\mathcal{U}} \rightsquigarrow \text{lim}_{i, \mathcal{U}} x_i
\]

(\( \sigma(E'', E') \)-limit) have the following properties: \( J_E \) is an isometry which extends the natural embedding \( E \hookrightarrow (E)_{\mathcal{U}} \), the mapping \( Q_E \) has norm 1 (if \( E \neq \{0\} \)) and \( J_E Q_E : (E)_{\mathcal{U}} \longrightarrow \text{im} J_E \cong E'' \) is a norm-1-projection. For \( q \in \mathcal{P}^n(E) \) define

\[
\overline{q} := \left\{ \lim_{i, \mathcal{U}} q \right\} \circ J_E \in \mathcal{P}^n(E''),
\]

and take a maximal normed ideal of \( n \)-homogeneous polynomials, \( q \in \mathcal{P}^n(E) \) and \( \mathcal{U} \) a local ultrafilter of \( E \). Then \( q \in \mathcal{Q}(E) \) if and only if \( \overline{q} \in \mathcal{Q}(E'') \); in this case \( \|q\|_{\mathcal{Q}} = \|q\|_{\mathcal{Q}} \).

In particular, this applies to the class of integral polynomials. Note that it took considerable effort to prove this result for the iterated Aron-Berner extension in the cases \( \mathcal{Q} := \mathcal{P}^n \) (Davie-Gamelin [DG]) and \( \mathcal{Q} := \{\text{integral polynomials}\} \) (due to [CZ]; in [F1 6.8] there is an alternative proof).

3.4. It is clear that a theorem like 3.1 holds also for normed ideals of \( n \)-linear functionals originally defined by Pietsch [P] in 1983: a subclass \( \mathcal{A} \) of all \( n \)-linear continuous functionals on Banach spaces is an ideal if (for all Banach spaces \( E_j \) and \( F_j \))

- \( \mathcal{A}(E_1, \ldots, E_n) := \mathcal{A} \cap \mathcal{L}(E_1, \ldots, E_n) \) is a linear subspace of \( \mathcal{L}(E_1, \ldots, E_n) \),
- if \( T_j \in \mathcal{L}(E_j; F_j) \) and \( \varphi \in \mathcal{A}(E_1, \ldots, E_n) \), then \( \varphi \circ (T_1, \ldots, T_n) \in \mathcal{A} \),
- \( \mathbb{K}^n \ni (x_1, \ldots, x_n) \mapsto x_1 \cdots x_n \in \mathbb{K} \) if \( x \in \mathcal{A} \).

If \( \| \cdot \|_{\mathcal{A}} : \mathcal{A} \longrightarrow [0, \infty] \) satisfies

- \( \| \cdot \|_{\mathcal{A}} \) is a norm on \( \mathcal{A}(E_1, \ldots, E_n) \),
- \( \| \varphi \circ (T_1, \ldots, T_n) \|_{\mathcal{A}} \leq \| T_1 \| \cdots \| T_n \| \| \varphi \|_{\mathcal{A}} \) in the situation of (b),
- \( \| \mathbb{K}^n \ni (x_1, \ldots, x_n) \mapsto x_1 \cdots x_n \in \mathbb{K} \|_{\mathcal{A}} = 1 \),

then \( (\mathcal{A}, \| \cdot \|_{\mathcal{A}}) \) is called a normed ideal of \( n \)-linear functionals. It is obvious from 3.2 how to define that \( (\mathcal{A}, \| \cdot \|_{\mathcal{A}}) \) is maximal or ultrastable. The same kind of ideas as in the proof of Theorem 3.2 gives the following:

**Theorem.** For every normed ideal \( (\mathcal{A}, \| \cdot \|_{\mathcal{A}}) \) of \( n \)-linear functionals the following statements are equivalent:

1. \( (\mathcal{A}, \| \cdot \|_{\mathcal{A}}) \) is maximal.
2. \( (\mathcal{A}, \| \cdot \|_{\mathcal{A}}) \) is ultrastable.
(3) There exists a finitely generated tensor norm $\beta$ of order $n$ with
\[
(\otimes_\beta(E_1, \ldots, E_n))' \cong A(E_1, \ldots, E_n)
\]
for all Banach spaces $E_1, \ldots, E_n$.

4. VECTOR-VALUED IDEALS OF POLYNOMIALS AND MULTILINEAR MAPPINGS

4.1. A normed ideal of $n$-homogeneous continuous vector-valued polynomials on Banach spaces is, by definition, a pair $(Q, \| \cdot \|_Q)$ such that:

(a) $Q(E; F) := Q \cap \mathcal{P}^n(E; F)$ is a linear subspace of $\mathcal{P}^n(E; F)$ and $\| \cdot \|_Q(Q(E; F))$ is a norm on it.
(b) If $T \in \mathcal{L}(E_1; E_2)$, $q \in Q(E_2; E_3)$ and $S \in \mathcal{L}(E_3; E_4)$, then $S \circ q \circ T \in Q$ and $\|S \circ q \circ T\|_Q \leq \|T\|^n \|q\|_Q \|S\|$. 
(c) $K \ni z \mapsto z^n \in k$ is in $Q$ and has norm 1.

4.2. We are only interested in ideals coming from tensor norms. For this the following notation will be used:
\[
\mathcal{L}(E; G') = (E \otimes_\pi G)', \quad T \mapsto \beta_T,
\]
\[
\mathcal{P}^n(E; G') = \mathcal{L}(\otimes_{\pi_n}^* E; G') = ((\otimes_{\pi_n}^* E) \otimes_\pi G)', \quad q \mapsto \beta_q := \beta_{\Delta_q}.
\]
Let $\alpha$ be a finitely generated $s$-tensor norm of order $n$ and $\beta$ a finitely generated tensor norm of order 2. We define $q \in \mathcal{P}^n_{(\alpha, \beta)}(E; F)$ if $\beta_{\Delta_{qF}}(E; F)$ and in this case $\|q\|_{(\alpha, \beta)} := \|\beta_{\Delta_{qF}}\|_{(\alpha, \beta)}$. It is easy to see that $\mathcal{P}^n_{(\alpha, \beta)}$ is a normed ideal in the sense of 4.1. If $C$ is the maximal Banach operator ideal associated with the dual tensor norm $\beta'$ of $\beta$, then from the representation theorem [DF, 17.5] we get
\[
\mathcal{P}^n_{(\alpha, \beta)}(E; F) = C(\otimes_{\alpha}^n E; F).
\]
A consequence of this is that $\mathcal{P}^n_{(\alpha, \beta)}$ is regular, i.e., $q \in \mathcal{P}^n_{(\alpha, \beta)}(E; F)$ if and only if $\Delta_{qF} \circ q \in \mathcal{P}^n_{(\alpha, \beta)}(E; F')$ and $\|q\|_{(\alpha, \beta)} = \|\Delta_{qF} \circ q\|_{(\alpha, \beta)}$. It is also rather routine to show that $\mathcal{P}^n_{(\alpha, \beta)}$ is maximal in the following sense: $q \in \mathcal{P}^n_{(\alpha, \beta)}(E; F)$ is in $\mathcal{P}^n_{(\alpha, \beta)}$ if
\[
\sup \{\|Q^E_L \circ q\|_{(\alpha, \beta)} | L \in \text{COFIN}(E), M \in \text{FIN}(E)\} < \infty
\]
and then this number is $\|q\|_{(\alpha, \beta)}$ (where COFIN$(E) := \{L \subset E/L$ finite-codimensional, closed subspace of $E\} = \{N^0 | N \in \text{FIN}(E')\}$ and $Q^E_L : F \rightarrow F/L$ the canonical quotient map). However, it seems to be unlikely that every maximal and regular $(Q, \| \cdot \|_Q)$ is of the form $\mathcal{P}^n_{(\alpha, \beta)}$, contrary to the scalar case.

Just one example: Since $[\otimes_{\alpha}^n E] \otimes_F F \rightarrow \mathcal{P}^n(E'; F)$, one can deduce from [JM, Lemma 2.1.] (see also [A2] for the reflexive case) that $\mathcal{P}^n_{\pi,F}(E; F')$ is the space of integral $n$-homogeneous polynomials $E \rightarrow F'$ in the sense of Alencar [A1].

**Theorem.** The ideal $\mathcal{P}^n_{(\alpha, \beta)}$ is ultrastable, i.e., if $\mathcal{U}$ is an ultrafilter on $I$ and $q_i \in \mathcal{P}^n_{(\alpha, \beta)}(E_i; F_i)$ such that $\sup \|q_i\|_{(\alpha, \beta)} < \infty$, then $\lim_{\mathcal{U}} q_i \in \mathcal{P}^n_{(\alpha, \beta)}(E_\mathcal{U}; F_\mathcal{U})$ and $\|q_i\|_{(\alpha, \beta)} \leq \lim_{\mathcal{U}} \|q_i\|_{(\alpha, \beta)}$.

See 1.4 for the notation.
Proof. Let \( V \in \mathcal{L}(\otimes_{\pi_e}^s(E_i)_\mathcal{U}; (F_i)_\mathcal{U}) \) be the operator associated with \( (q_i)_\mathcal{U} \). One has to show that \( \bar{V} \in \mathcal{C}(\otimes_{\pi_e}^s(E_i)_\mathcal{U}; (F_i)_\mathcal{U}) \) where \( (\mathcal{C}, \mathcal{C}) \) is the Banach operator ideal associated with \( \beta' \) and \( \bar{V} \) is the extension of \( V \) to the completion \( \otimes_{\alpha}^s(E_i)_\mathcal{U} \). From the main theorem in Section 2 we get

\[
\varphi' := \lim_{\mathcal{U}} \beta_{x_{F_i} \circ \varphi} \in \left( (\otimes_{\alpha}^s(E_i)_\mathcal{U}) \otimes_{\beta} (F_i')_\mathcal{U} \right) =: H
\]

and \( \|\varphi'\|_H \leq \lim \|q_i\|_{(\alpha, \beta)} \). If \( \varphi' = \beta_{x_{F_i}} \) with \( U \in \mathcal{L}(\otimes_{\pi_e}^s(E_i)_\mathcal{U}; (F_i)_\mathcal{U}) \) (hence \( \mathcal{C}(U) = \|\varphi'\|_H \)), then \( U = K \circ \bar{V} \) where \( K : (F_i)_\mathcal{U} =: F \to (F_i')_\mathcal{U} =: G' \) is the natural mapping from 1.6 (check on \( [\otimes_n(x_i)_\mathcal{U}] \otimes (x_i')_\mathcal{U} \)). Using maximality it is enough to show that

\[
\|M \to \otimes_{\alpha}^s(E_i)_\mathcal{U} \bar{V} \to F Q_{N^0}^F F/N^0 = N'\| \leq \|\varphi'\|_H
\]

for all \( M \in \text{FIN}(\otimes_{\alpha}^s(E_i)_\mathcal{U}) \) and \( N \in \text{FIN}(F') \). With \( L := \bar{V}(M) \subset F \) the local duality 1.6 of ultraproducts gives an operator \( T \in \mathcal{L}(N; G) \) with \( \|T\| = 1 \) and

\[
\langle K\bar{V}(u), T x_i' \rangle_{G', G} = \langle x_i', \bar{V}(u) \rangle_{F', F} = \langle Q_{N^0}^F \bar{V}(u), x_i' \rangle_{N', N}
\]

for all \( u \in M \) and \( x_i' \in N \). This means \( Q_{N^0}^F \circ \bar{V} \mid_M = T' \circ K \circ \bar{V} \mid_M \). It follows that \( \mathcal{C}(Q_{N^0}^F \circ \bar{V} \mid_M) \leq \|T'\| = \mathcal{C}(K \circ \bar{V} \mid_M) = \mathcal{C}(U \mid_M) \leq \|\varphi'\|_H \) and therefore \( \|\varphi\|_{(\alpha, \beta)} = \mathcal{C}(\bar{V}) \leq \lim \|q_i\|_{(\alpha, \beta)} \). \( \square \)

4.3. Note the special case \( \beta = \pi \) and \( q_0^1 : E_i \to \otimes_{\alpha}^s E_i \) being the “canonical” polynomial \( q_0^1(x) := \otimes x, \ i.e., \ (q_0^1)^L = \text{id}_{\otimes_{\alpha}^s E_i} \) and \( \|q_0^1\|_{(\alpha, \pi)} = 1 \). Then \( (q_0^1)_\mathcal{U} \) is in \( \mathcal{P}_{\alpha, \pi}((E_i)_\mathcal{U}; (\otimes_{\alpha}^s E_i)_\mathcal{U}) \) which means that the natural map

\[
\otimes_{\alpha}^s(E_i)_\mathcal{U} \to (\otimes_{\alpha}^s E_i)_\mathcal{U}
\]

defined by \( \otimes_n(x_i)_\mathcal{U} \to (\otimes_n x_i)_\mathcal{U} \) has norm \( \leq 1 \), if \( \alpha \) is a finitely generated s-tensor norm.

4.4. For any ultrafilter \( \mathcal{U} \) and normed space \( F \) the map \( Q_F : (F)_\mathcal{U} \to F'' \) from 3.3 is well-defined, extends the natural embedding \( F \to (F)_\mathcal{U} \) and satisfies

\[
\langle Q_F((y_i)_\mathcal{U}), y'' \rangle_{F'', F} = \lim_{i, \mathcal{U}} \langle y_i, y'' \rangle_{F, F'}
\]

If \( \mathcal{U} \) is a local ultrafilter of another space \( E \) and \( q \in \mathcal{P}_n(E; F) \), then (see 3.3 for the notation)

\[
\mathfrak{q}_\mathcal{U} := Q_F \circ (q)_\mathcal{U} \circ J_E : E'' \to F''
\]

is an \( n \)-homogeneous polynomial which extends \( q \) and can be calculated as follows:

\[
\langle \mathfrak{q}_\mathcal{U}(x''), y'' \rangle_{F'', F} = \lim_{i, \mathcal{U}} \langle q(f_i(x'')), y'' \rangle.
\]

Theorem 4.2 and the regularity of \( \mathcal{P}_n^{(\alpha, \beta)} \) imply the following:

**Corollary.** Take \( q \in \mathcal{P}_n(E; F) \) and a local ultrafilter on \( E \). Then the extension \( \mathfrak{q}_\mathcal{U} \)

is in \( \mathcal{P}_n^{(\alpha, \beta)}(E''; F'') \) if and only if \( q \) is; in this case \( \|q\|_{(\alpha, \beta)} = \|\mathfrak{q}_\mathcal{U}\|_{(\alpha, \beta)} \).
4.5. For \( n \)-linear operators \( E_1 \times \cdots \times E_n \to F \) the same ideas apply: a normed ideal of \( n \)-linear continuous operators between Banach spaces is a pair \((\mathcal{A}, \| \cdot \|_{\mathcal{A}})\) such that

(a) \( \mathcal{A}(E_1, \ldots, E_n; F) = \mathcal{A} \cap \mathcal{L}(E_1, \ldots, E_n; F) \) is linear and \( \| \cdot \|_{\mathcal{A}}|_{\mathcal{A}(E_1, \ldots, E_n; F)} \) is a norm.

(b) if \( T_j \in \mathcal{L}(G_j; E_j) \), \( \varphi \in \mathcal{A}(E_1, \ldots, E_n; F) \) and \( S \in \mathcal{L}(F; G) \), then the composition \( S \circ \varphi \circ (T_1, \ldots, T_n) \) is in \( \mathcal{A} \) and

\[
\| S \circ \varphi \circ (T_1, \ldots, T_n) \|_{\mathcal{A}} \leq \| S \| \| \varphi \|_{\mathcal{A}} \| T_1 \| \cdots \| T_n \|,
\]

(c) \( \mathbb{K}^n \ni (x_1, \ldots, x_n) \mapsto x_1 \cdots x_n \in \mathbb{K} \) is in \( \mathcal{A} \) and \( \| \cdot \|_{\mathcal{A}} = 1 \).

Every tensor norm \( \beta \) of order \( n + 1 \) defines an ideal \( \mathcal{A}_\beta \) as follows: an \( n \)-linear map \( \varphi \) is in \( \mathcal{A}_\beta(E_1, \ldots, E_n; F) \) if and only if the \((n+1)\)-linear form associated with \( \varphi_F \circ \varphi \) is in \( \oplus_\beta(E_1, \ldots, E_n, F^\prime) \).

An ideal \((\mathcal{A}, \| \cdot \|_{\mathcal{A}})\) is called maximal if

\[
\| \varphi \|_{A_{\text{max}}} := \sup \{ \| Q_L^F \circ \varphi \|_{M_1 \times \cdots \times M_n} \|_{\mathcal{A}} \mid M_j \in \text{FIN}(E_j), \ L \in \text{COFIN}(F) \} < \infty
\]

implies \( \varphi \in \mathcal{A} \) and \( \| \varphi \|_{\mathcal{A}} = \| \varphi \|_{A_{\text{max}}} \) holds. The ideal is called regular if \( \mathcal{A}_\beta \circ \varphi \in \mathcal{A}(E_1, \ldots, E_n; F^\prime) \) implies \( \varphi \in \mathcal{A} \) and \( \| \varphi \|_{\mathcal{A}} = \| \mathcal{A}_\beta \circ \varphi \|_{\mathcal{A}} \); it is easy to see that the ideals \( \mathcal{A}_\beta \) are regular. \( \mathcal{A} \) is ultrastable if for \( \varphi \in \mathcal{A}(E_1, \ldots, E_n; F) \) with \( \| \varphi \|_{\mathcal{A}} \leq c \) the operator \((\varphi)_{\mathcal{U}}\) is in \( \mathcal{A}(\text{FIN}(E_1), \ldots, \text{FIN}(E_n); (F_1)_{\mathcal{U}}) \) and \( \| (\varphi)_{\mathcal{U}} \|_{\mathcal{A}} \leq \sup \| \varphi \|_{\mathcal{A}} \).

**Theorem.** Let \((\mathcal{A}, \| \cdot \|_{\mathcal{A}})\) be a normed ideal of \( n \)-linear continuous mappings between Banach spaces. Then the following statements are equivalent:

1. \((\mathcal{A}, \| \cdot \|_{\mathcal{A}})\) is maximal.
2. \((\mathcal{A}, \| \cdot \|_{\mathcal{A}})\) is ultrastable and regular.
3. There is a finitely generated tensor norm \( \beta \) of order \( n + 1 \) such that

\[
\mathcal{A}(E_1, \ldots, E_n; F) = (\oplus_\beta(E_1, \ldots, E_n, F))^\prime \cap \mathcal{L}(E_1, \ldots, E_n; F).
\]

**Proof.** (1) \( \cap \) (3) runs exactly as in the case \( n = 1 \) (see [DF, 17.5.], the extension lemma holds also for finitely generated tensor norms of arbitrary order) with a construction of \( \beta \) as in the proof of Theorem 4.2.

(3) \( \cap \) (2). Ultrastability follows from the main theorem as in the proof of Theorem 4.2; the regularity follows immediately when looking at the \((n+1)\)-linear functionals appearing in the two formulae in (3).

(2) \( \cap \) (1). Take \( \varphi \in \mathcal{L}(E_1, \ldots, E_n; F) \) with \( \| \varphi \|_{A_{\text{max}}} < \infty \). Following Heinrich’s proof for the case \( n = 1 \) (see [H]) consider \( I := \text{FIN}(E_1) \times \cdots \times \text{FIN}(E_n) \times \text{FIN}(F^\prime) \) and let \( \mathcal{U} \) be an ultrafilter finer than the order filter. For \( \iota = (M_1, \ldots, M_n, N) \) define \( E_{k,\iota} := M_k \) and \( F_\iota := F/N^0 \) and metric embeddings

\[
J_k : E_k \to (E_{k,\iota})_{\mathcal{U}} \quad x_k \mapsto (x_{k,\iota})_{\mathcal{U}}
\]

where \( x_{k,\iota} = x_k \) if \( x_k \in M_k \) and \( = 0 \) otherwise. Moreover, define a mapping \( Q : (F_\iota)_{\mathcal{U}} \to F^0 \) by

\[
(Q(y_{\iota}))_{\mathcal{U}} \mapsto \lim_{\mathcal{U}} (y_{\iota}, y^\prime_{\iota})
\]

where \( y^\prime_{\iota} = y^\prime \) if \( y^\prime \in N \) and \( = 0 \) otherwise; \( Q \) has norm \( \leq 1 \).

For \( \varphi := Q_{N^0} \circ \varphi \big|_{M_1 \times \cdots \times M_n} \) one obtains

\[
\varphi_F \circ \varphi = Q \circ (\varphi_{\mathcal{U}})_{\mathcal{U}} \circ (J_1, \ldots, J_n) \in \mathcal{A}
\]
with \( \| \varphi \|_A \leq \lim_i \| \varphi \|_{A^{n+i}} \); the regularity gives \( \varphi \in A \), and \( \| \varphi \|_A = \| \varphi^* \|_A \leq \| \varphi \|_{A^{\max}} \).

For \( n = 1 \) the equivalence (1) \( \Leftrightarrow \) (2) is the Heinrich-Kursten result for Banach operator ideals and (2) \( \Leftrightarrow \) (3) Lotz’ representation theorem. Note that the result implies that all \( \mathcal{A}(E_1, \ldots, E_n; F) \) are Banach spaces if \( (\mathcal{A}, \| \cdot \|_A) \) is maximal.

4.6. As in 4.3 one obtains that the natural map
\[
\bigotimes_{\gamma,k=1}^n (E_{k,i})_1 \to \left( \bigotimes_{\gamma,k=1}^n E_{k,i} \right)_1
\]
defined by \( (x_i^1)_{1} \otimes \cdots \otimes (x_i^n)_{1} \to (x_i^1 \otimes \cdots \otimes x_i^n)_1 \) has norm \( \leq 1 \) if \( \gamma \) is a finitely generated tensor norm or order \( n \). For a proof define the tensor norm \( \beta \) of order \( n + 1 \) by
\[
\bigotimes \beta(E_1, \ldots, E_n, E_{n+1}) := \left[ \bigotimes_{\gamma}(E_1, \ldots, E_n) \right] \bigotimes_{\pi} E_{n+1},
\]
and apply the theorem to \( \otimes : E_{1,i} \times \cdots \times E_{n,i} \to \bigotimes_{\gamma}(E_1, \ldots, E_{n,i}) =: F_i \).
