A NOTE ON BESOV REGULARITY OF LAYER POTENTIALS AND SOLUTIONS OF ELLIPTIC PDE’S

MARIUS MITREA

(Communicated by Andreas Seeger)

Abstract. Let $L$ be a second order, (variable coefficient) elliptic differential operator and let $u \in B^{p,p}_\alpha(\Omega)$, $1 < p < \infty$, $\alpha > 0$, satisfy $Lu = 0$ in the Lipschitz domain $\Omega$. We show that $u$ can exhibit more regularity on Besov scales for which smoothness is measured in $L^\tau$ with $\tau < p$. Similar results are valid for functions representable in terms of layer potentials.

1. Introduction and statement of results

Let $\Omega$ be a bounded Lipschitz domain in $\mathbb{R}^d$ (cf. [12]) and, for each $h \in \mathbb{R}^d$, denote by $\Omega_h$ the collection of all $x \in \Omega$ with the property that the line segment $[x, x + h]$ is contained in $\Omega$. Then the modulus of smoothness of a function $u \in L^p(\Omega)$, $0 < p < \infty$, is defined by

$$\omega_r(u, t)_{L^p(\Omega)} := \sup \{ \| \Delta^r_h(u, \cdot) \|_{L^p(\Omega_h)} ; |h| \leq t \}, \quad t > 0,$$

where $\Delta^r_h$ stands for the $r$-th difference with step $h$. Then, for $\alpha > 0$ and $0 < p, q < \infty$, the Besov space $B^{p,q}_\alpha(\Omega)$ is introduced as the space of all functions $u$ for which

$$\| u \|_{B^{p,q}_\alpha(\Omega)} := \| u \|_{L^p(\Omega)} + \left( \int_0^\infty [t^{-\alpha} \omega_r(u, t)_{L^p(\Omega)}]^q \, dt / t \right)^{1/q} < +\infty,$$

where $r := [\alpha] + 1$. For more on this the reader is referred to [4]. Here we only want to make the important observation that this definition coincides with the one based on the Fourier transform and Littlewood-Paley theory as in, e.g., [1] p. 140 provided that $\alpha/d > \max \{0, 1/p - 1 \}$. See [13] p. 41 for a proof.

The main concern for us here is a certain ‘smoothing’ phenomenon, first observed in the context of harmonic Besov spaces in [2]. More specifically, it has been shown in [2] that if $u \in B^{p,p}_\lambda(\Omega)$ with $1 < p < \infty$, $\lambda > 0$, is a harmonic function, then also

$$u \in B^{p,\tau}_\alpha(\Omega) \quad \text{for each} \quad \lambda \leq \alpha < \lambda d/(d-1), \quad \text{if} \quad 1/\tau = 1/p + \alpha/d.$$

Thus, harmonic functions in Besov spaces could exhibit more smoothness, when considered on appropriate, alternative scales (note that this is accomplished at the expense of lowering the integrability exponent). This phenomenon is significant when dealing with the issue of regularity for boundary-value problems for Laplace’s
equation, as well as for determining the efficiency of certain nonlinear approximation methods (such as those involving wavelet-based Galerkin schemes). See [2], [3], for a more extensive discussion in this regard.

The aim of this note is to investigate similar phenomena in the context of more general PDE’s. Here we deal with null-solutions of (variable coefficient) elliptic, second order differential operators, and with functions representable by means of layer potentials. In order to state our main results, consider a smooth, compact, boundaryless, Riemannian manifold $M$, of real dimension $d$. Also, let $L$ be a second order, elliptic differential operator in $M$ locally given by

$$Lu = \sum_{j,k} \partial_j A^{jk} \partial_k u + \sum_j B^j \partial_j u - V u$$  \hspace{1cm} (1.4)

where $A^{jk} := \left( a_{jk}^{\alpha \beta} \right)_{\alpha,\beta}$, $B^j := \left( b_j^{\alpha \beta} \right)_{\alpha,\beta}$ and $V := \left( v^{\alpha \beta} \right)_{\alpha,\beta}$ are matrix-valued functions with entries satisfying

$$a_{jk}^{\alpha \beta} \in \mathrm{Lip}, \quad b_j^{\alpha \beta} \in L^{p^*}_{1}, \quad v^{\alpha \beta} \in L^{p^*}, \quad \text{for some } p^* > d.$$  \hspace{1cm} (1.5)

Here and elsewhere, $L^p_s$, $1 < p < \infty$, $s \in \mathbb{R}$, will stand for the usual Sobolev scale. For definitions and basic properties the reader is referred to [6].

Throughout this note, for each point $(x_0,y_0)$ in the first quadrant in $\mathbb{R}^2$, we set $\Theta^d(x_0,y_0)$ for the collection of all points $(x,y)$ such that either $y_0 \leq y < 1 + x/d$ and $y - y_0 + x_0 > x > 0$, or $0 < y < y_0$ and $d(y - y_0) + x_0 \geq x > 0$. In other words, $\Theta^d(x_0,y_0) \subset \mathbb{R}^2$ is the polygonal region in the first quadrant bordered by the lines passing through $(x_0,y_0)$ and having slopes 1 and $1/d$, and the line passing through $(0,1)$ and having slope $1/d$.

**Theorem 1.1.** Let $\Omega$ be a Lipschitz subdomain of $M$, and let $L$ be as in (1.4)–(1.5). Next assume that $0 < \alpha < 1$, $p^*/(p^* - 1) < p < p^*$, and that $u \in B^p_{\alpha,p}(\Omega)$ satisfies $Lu = 0$ in $\Omega$. Then also $u \in B^\infty_{\alpha,p}(\Omega)$, provided

$$(\gamma, 1/\tau) \in \Theta^d(\alpha, 1/p) \quad \text{and} \quad 2 - \alpha > \frac{1}{\tau} - \frac{1}{p}.$$  \hspace{1cm} (1.6)

Moreover, if (1.5) is strengthened to

$$a_{jk}^{\alpha \beta}, b_j^{\alpha \beta} \in C^{1+\varepsilon}, \quad \text{some } \varepsilon > 0, \quad v^{\alpha \beta} \in L^\infty,$$  \hspace{1cm} (1.7)

then the same conclusion holds for $1 < p < \infty$.

What makes this type of result nontrivial is the fact that the source of the extra smoothness for $u$ is the fulfillment of the partial differential equation $Lu = 0$. For maximum applicability it is important to allow nonsmooth domains and operators whose coefficients have only a limited amount of smoothness. Note that the vector-valued case is covered as well.

To state our next result, let $Du := \sum a_j \partial_j u + bu$ be an elliptic, first-order differential operator on $M$, whose (matrix-valued) coefficients are assumed to satisfy

$$a_{jk}^{\alpha \beta} \in L^p_{2}, \quad b^{\alpha \beta} \in L^p_{1} \quad \text{for some } p^* > d = \dim M.$$  \hspace{1cm} (1.8)

Note that if all metrics involved are of class $L^p_2$, then the coefficients of $D^*$, the formal adjoint of $D$, also satisfy (1.8). In particular,

$$L := -D^* D$$  \hspace{1cm} (1.9)
is a formally self-adjoint, strongly elliptic operator whose coefficients, in the writing (1.4), satisfy
\[ a^{\alpha\beta}_{jk} \in L^p_{\infty}, \quad b^{\alpha\beta}_j \in L^p_{\frac{1}{2}}, \quad v^{\alpha\beta} \in L^p. \]

The operator \( D \) is said to have the unique continuation property (abbreviated \( D \in \text{UCP} \) henceforth) if
\[ u \in L^2_1(M), \quad Du = 0 \text{ on } M \Rightarrow \supp u \text{ is either } M \text{ or empty.} \]

**Theorem 1.2.** Let \( \Omega \) be a Lipschitz subdomain of \( M \), and let \( L \) satisfy either of the following two conditions:

(i) \( L \) is as in (1.8)-(1.10), where \( D \in \text{UCP} \);

(ii) \( L \) is a formally self-adjoint, second-order, strongly elliptic differential operator whose coefficients satisfy (1.4)-(1.5).

Also, assume that \( u \in L^p_{s+\frac{1}{p}}(\Omega) \) satisfies \( Lu = 0 \) in \( \Omega \). Then, if \( p^*/(p^*-1) < p < p^* \), \( 0 < s < 1 \),
\[ u \in B^{\gamma, \tau}_{s+1/p}(\Omega) \text{ provided } (\gamma, 1/\tau) \in \Theta(s+1/p, 1/p), \]
provided either \( L \) is as in (i) above, or \( p = 2 \) and \( L \) is as in (ii) above. The same conclusion holds for \( 1 < p < \infty \) granted that \( L \) is as in (i) above and its coefficients satisfy (1.7).

Furthermore, when \( p = 2 \) and \( s \in \{0, 1\} \), then also
\[ u \in B^{p+2}_{p+2/q}(\Omega) \text{ for each } 1 < q \leq 2. \]

A few comments are in order here.

**Remarks.** (i) An important case when Theorem 1.2 applies occurs for \( D = \text{grad on a Riemannian manifold } M \), which entails \( L = \Delta \), the Laplace-Beltrami operator on \( M \).

(ii) At the level of Dirac operators (with reasonably smooth coefficients; cf. [9] for precise conditions) \( D \) on \( M \), we have
\[ u \in B^{p,p}_{s+1/p}(\Omega), \quad 0 < s < 1, \quad 1 < p < \infty, \quad Du = 0 \text{ in } \Omega \quad \Rightarrow \quad \]
\[ u \in B^{\gamma, \tau}_{s+1/p}(\Omega) \text{ for each } (\gamma, 1/\tau) \in \Theta(s+1/p, 1/p). \]

(iii) Finally, Theorem 1.2 (as well as the just mentioned extensions) can be used in concert with Theorem 1.1 to produce further new regularity results. We leave the details to the reader.

Next, turning attention to integral operators, assume that the kernel \( k(x, y) \) is defined on \( M \times M \setminus \text{diagonal} \). Then, for a (fixed) domain \( \Omega \) in \( M \) consider the (layer potential type) operator
\[ Kf(x) := \langle k(x, \cdot) \mid_{\partial \Omega}, f \rangle, \quad x \in \Omega, \]
where \( \langle \cdot, \cdot \rangle \) stands for the natural pairing between classes of distributions and their corresponding test functions on \( \partial \Omega \). Finally, \( B^{p,q}_{\partial \Omega}(\partial \Omega), \quad 1 < p, q < \infty, \quad s \in \mathbb{R} \), will denote the usual Besov scale on \( \partial \Omega \); cf., e.g., [6].
Theorem 1.3. Let $\Omega$ be a Lipschitz domain in $M$ and assume that, for a positive integer $N$ and some non-negative integer $\theta$, the kernel $k(x, y)$ satisfies

\begin{equation}
|\nabla^i_x \nabla^j_y k(x, y)| \leq C \text{dist} (x, y)^{(d-1-\theta+i+j)}, \quad \forall \, i = 0, 1, \ldots, N, \, \forall \, j = 0, 1,
\end{equation}

where the constant $C > 0$ is independent of $x, y$. Also, recall the integral operator $K$ associated with $k(x, y)$ as in (1.15). Then the operator

\begin{equation}
K : B^{p,p}_{-\theta}(\partial \Omega) \longrightarrow B^\gamma_{\tau,\gamma}(\Omega)
\end{equation}

is bounded in each of the following situations:

\begin{align}
0 < s < 1, \quad 1 < p < \infty, \quad \theta \geq 1 \quad \text{and} \\
N > 1 - s + \frac{1}{\tau}, \quad (\gamma, 1/\tau) \in \Theta^d(\theta + 1/p - s, 1/p),
\end{align}

or

\begin{align}
0 < s < 1/p < 1, \quad \theta = 0 \quad \text{and} \\
N > 1 - s + \frac{1}{\tau}, \quad (\gamma, 1/\tau) \in \Theta^d(1/p - s, 1/p).
\end{align}

A natural class of functions $k(x, y)$ for which (1.16) holds consists of Schwartz kernels of pseudodifferential operators of order $-1-\theta$ on $M$. In this latter case, we also have the following result.

Theorem 1.4. Let $k(x, y)$ denote the Schwartz kernel of a (classical) pseudodifferential operator $P \in \text{OPS}^{-1-\theta}(M)$ and let $K$ be associated with $k(x, y)$ as in (1.15). Assume that the principal symbol $\sigma(P; x, \xi)$ is even in $\xi$ when $\theta$ is odd, and odd in $\xi$ when $\theta$ is even. Then, for each $0 \leq s \leq 1$, the operator

\begin{equation}
K : L^2_{-s}(\partial \Omega) \longrightarrow B^\gamma_{\tau,\gamma}(\Omega)
\end{equation}

is bounded provided

\begin{equation}
(\gamma, 1/\tau) \in \Theta^d(\theta - s + 1/2, 1/2), \quad \tau > 1, \quad \theta \geq 1.
\end{equation}

The same conclusion also holds when $\theta = 0$ and $s = 0$.

These regularity results are valid for large classes of PDE's in Lipschitz domains, including the Hodge Laplacian (on a manifold whose metric has only a limited amount of smoothness), as well as the Lamé and the Stokes system. Also, via standard methods, they can be easily extended to encompass (inhomogeneous) Poisson type problems for such systems.

2. Proofs

We debut with a result inspired by the work in [2]. Recall that $\dim M = d$.

Proposition 2.1. Let $\Omega$ be a Lipschitz domain in $M$ and consider a function $v \in B^{\lambda(p),p}_{\theta}(\Omega)$, for some $\lambda > 0$ and $1 < p < \infty$. Fix two parameters $\alpha > 0, \tau > 0$ satisfying

\begin{equation}
\alpha/d > \max \{0, 1/\tau - 1\},
\end{equation}

and either

\begin{equation}
\frac{1}{\tau} > \frac{1}{p}, \quad \alpha - \frac{1}{\tau} < \lambda - \frac{1}{p},
\end{equation}

License or copyright restrictions may apply to redistribution; see https://www.ams.org/journal-terms-of-use
or
\[
\alpha < \lambda, \quad \frac{1}{\tau} - \frac{\alpha}{d} \geq \frac{1}{p} - \frac{1}{\lambda},
\]
and pick an integer \( m \) such that
\[
m > \lambda - \frac{1}{p} + \frac{1}{\tau}.
\]
Also, assume \( \nabla^m v \in L^1_{\text{loc}}(\Omega) \) and
\[
\text{dist}(\cdot, \partial \Omega)^m - \lambda |\nabla^m v| \in L^p(\Omega).
\]
Then it follows that \( v \in B^\tau,\tau_{\alpha}(\Omega) \).

Note that the assumptions (2.1)-(2.3) made on \( \alpha \) and \( \tau \) amount precisely to the requirement that the point with coordinates \((\alpha, 1/\tau)\) belongs to the region \( \Theta^d(\lambda, 1/p) \).

**Proof.** The case when (2.3) is satisfied follows directly from well-known embedding theorems. Thus, henceforth we shall assume that (2.2) holds. In particular, \( \tau \in (0, p) \).

Next, since the problem is local in character, there is no loss of generality in assuming that \( \Omega \) is a bounded, Euclidean Lipschitz domain. In this context, we shall closely parallel the arguments in the proof of Theorem 3.2 in [2]. In fact, in the interest of brevity, we shall adopt the notation utilized in [2], sketch the main steps and only insist on the modifications which become necessary as a result of dropping the hypothesis \( 1/\tau = \alpha/d + 1/p \) which was enforced throughout [2].

Consider a sufficiently smooth wavelet basis, generated via the usual dilation-translation procedure by a family of functions \( \eta \in \Psi \), compactly supported in some large cube \( Q \) centered at the origin. Extending \( v \) to \( B^p_{\alpha}(\mathbb{R}^d) \) and relying on a characterization of membership to the Besov scale in terms of wavelet coefficients ([5], [7]), the goal is to show that
\[
\sum_{\eta \in \Psi} \sum_{I \in D^+} |I|^{-\alpha \tau/d} |\langle v, \eta_{I, \tau'} \rangle| \tau
= \sum_{\eta \in \Psi} \sum_{I \in D^+} |I|^{\tau(1/\tau - 1/p - \alpha/d)} |\langle v, \eta_{I, \tau'} \rangle| \tau < \infty.
\]

Here \( D^+ \) is the collection of all dyadic cubes \( I \) of volume \( |I| \leq 1, 1/\tau + 1/\tau' = 1 \) and \( \eta_{I, \tau'} \) stands for \( |I|^{1/2 - 1/\tau'} 2^{jd/2} \eta(2^j \cdot - k) \) if \( I = 2^{-j}(k + [0, 1]^d), \) \( k \in \mathbb{Z}^d, j \in \mathbb{Z}, \) \( \eta \in \Psi \).

Compared to [2], the factor \( |I|^{\tau(1/\tau - 1/p - \alpha/d)} \) in (2.6) is new and our aim is to monitor its effect on subsequent calculations. Let \( D^\tau_\alpha \) be the subset of \( D^+ \) consisting of dyadic cubes \( I = 2^{-j}(k + [0, 1]^d) \in D^+ \) such that \( Q(I) := 2^{-j}(k + Q) \) is contained inside \( \Omega \) and lies at a distance \( \geq 2^{-j} \) to the boundary. When the range of summation
in (2.6) is restricted to $\Lambda^j_\alpha$, it follows that $|I| = 2^{-jd}$ so that

\[(2.7) \sum_{\eta} \sum_{I \in \Lambda^j_\alpha} |I|^\frac{1}{\tau - 1/p - \alpha/d} \langle v, \eta_I, p' \rangle |^\tau \]

\[\leq C 2^{-jd} \left(1/\tau - 1/p - \alpha/d\right)^{-j\tau} \left(\sum_{I \in \Lambda^j_\alpha} \text{dist} (Q(I), \partial \Omega)^{p\tau(\lambda - m)/(p - \tau)}\right)^{(p - \tau)/p} \]

\[\times \left(\int_\Omega |\text{dist}(\cdot, \partial \Omega)^{m - \lambda} |\nabla^m u| |p| \right)^{\tau/p} \]

\[\leq C 2^{-jd} \left(1/\tau - 1/p - \alpha/d\right)^{-j\tau} \left(\sum_{k=1}^{C \cdot 2^{-j(d-1)}} k^{2^{-j} \tau(\lambda - m)/(p - \tau)}\right)^{(p - \tau)/p} \]

\[\leq C 2^{-jd} \left(\sum_{k=1}^{\infty} k^{p\tau(\lambda - m)/(p - \tau)}\right)^{(p - \tau)/p}. \]

This sequence of inequalities can be justified as in [2], based on classical Whitney estimates and Hölder’s inequality. The important observation is that, thanks to the second inequality in (2.4), the exponent of $k$ above is $-1$. Hence, the last series above converges, leading to an overall bound of the order $2^{-jd} \left(1/\tau - 1/p - \alpha/d\right)$. Now, since $\sum_{j=0}^{\infty} 2^{-jd} \left(1/\tau - 1/p - \alpha/d\right) < +\infty$ (as the first inequality in (2.4) guarantees), the corresponding piece in (2.6) is taken care of.

There remains the part in (2.6) when the sum is performed over the layers $\Lambda^j_{j,0}$, $j = 0, 1, \ldots$, defined analogously to $\Lambda^j_\alpha$ with the sole exception that, this time, the distance from $Q(I)$ to $\partial \Omega$ is assumed $\leq 2^{-j}$. Once again, this is dealt with much as in [2] but carrying along the factor $2^{-jd} \left(1/\tau - 1/p - \alpha/d\right)$. Ultimately, this yields

\[(2.8) \sum_{j=0}^{\infty} \sum_{\eta \in \Psi} \sum_{I \in \Lambda^j_{j,0}} |I|^{\frac{1}{\tau - 1/p - \alpha/d}} \langle v, \eta_I, p' \rangle |^\tau \]

\[\leq C \|v\|_{L^p_{\theta^{ij}, \tau} (\Omega)}^\tau \left(\sum_{j=0}^{\infty} 2^{-j\tau(\lambda + \alpha + 1/\tau - 1/p)}\right)^{(p - \tau)/p}. \]

Note that, due to our assumptions, the last sum above is finite. Thus (2.6) follows and this finishes the proof of the proposition.

Turning attention to layer potentials, we shall need the following.

**Proposition 2.2.** Let $\Omega$ be a Lipschitz domain in $M$ and consider a positive integer $N$. Suppose that the kernel $k(x, y)$ is defined on $M \times M \setminus$ diagonal and satisfies (1.10). Also, let $K$ be the integral operator with kernel $k(x, y)$ as in (1.13).

Then, for $1 < p < \infty$ and $0 < s < 1$, this operator satisfies the estimates

\[(2.9) \|\text{dist} (\cdot, \partial \Omega)^{s+i-1/p} |\nabla^{\theta + i} kf|\|_{L^p(\Omega)} \]

\[+ \sum_{k=0}^{\theta + i} \|\nabla^{[\theta + i - k]} kf\|_{L^p(\Omega)} \leq C \|f\|_{L^p_{\theta^{ij}, \tau} (\partial \Omega)} \]

\[+ \sum_{k=0}^{\theta + i} \|\nabla^{[\theta + i - k]} kf\|_{L^p(\Omega)} \leq C \|f\|_{B_{\theta^{ij}, \tau} (\partial \Omega)} \]
for all $i = 0, 1, \ldots, N-1$, uniformly for $f$ in $B_{s,x}^{p,p}(\partial \Omega)$. Here $[a]_+ := \max\{a,0\}$ and $\nabla^0$ is the identity. Furthermore, the operator
\begin{equation}
K : B_{s,x}^{p,p}(\partial \Omega) \to B_{\theta-s+1/p}^{p,p}(\Omega)
\end{equation}
is bounded in each of the following situations:
\begin{equation}
0 < s < 1 \quad \text{and} \quad \theta \geq 1,
\end{equation}
or
\begin{equation}
\theta = 0 \quad \text{and} \quad 0 < s < 1/p.
\end{equation}

**Proof.** The estimate (2.10) has been proved in [11] (which, in turn, builds on the results of [8] and [10]). The claim regarding (2.12) has also been established in [11] for $\theta \in \{0,1\}$ from which the general case needed here also follows.

**Proposition 2.3.** Let $k(x,y)$ denote the Schwartz kernel of a (classical) pseudodifferential operator $P \in OPS^{-1-\theta}(M)$ satisfying the hypotheses of Theorem 1.4. Then, for each $1 < p < \infty$, the operator
\begin{equation}
K : L^p_{\alpha,s}(\partial \Omega) \to B_{\theta-s+1/p}^{p,p}(\Omega), \quad \hat{p} := \max\{p,2\},
\end{equation}
is well-defined and bounded provided either $\theta = 0$ and $s = 0$, or $\theta \geq 1$ and $0 \leq s \leq 1$. Moreover, for $s \in \{0,1\}$,
\begin{equation}
\text{dist}(\cdot, \partial \Omega)^{1/2}|\nabla^{1+s}Kf| \in L^2(\Omega), \quad \forall f \in L^2_{\alpha,s}(\partial \Omega).
\end{equation}

**Proof.** Again, for $\theta \in \{0,1\}$, the claim regarding (2.12) has been proved in [11]. Clearly, the case of arbitrary $\theta$ also follows from this. Finally, (2.13) has been obtained in [8] when $s = 0$ and the case $s = 1$ can be deduced from this (by proceeding as in §3 of [11]).

After these preliminaries, we are ready to present the proofs of the main results.

**Proof of Theorem 1.1.** Under the current assumptions, Lemma 4.5 in [10] gives that
\begin{equation}
\text{dist}(\cdot, \partial \Omega)^{1-\alpha}|\nabla u| \in L^p(\Omega).
\end{equation}
Interior estimates (cf. Proposition 3.2 in [10] which continues to hold for $s < 0$) then further yield
\begin{equation}
\text{dist}(\cdot, \partial \Omega)^{2-\alpha}|\nabla^2 u| \in L^p(\Omega),
\end{equation}
so that (2.5) holds with $m = 2$. In particular, granted the current hypotheses, the inequalities (2.4) are satisfied. Then the desired conclusion (in the first part of the statement) follows from Proposition 2.1.

Finally, the second claim in the theorem is proved similarly given that (2.14) holds for any $1 < p < \infty$ under the stronger smoothness assumptions (1.4); cf. §3 in [10].

**Proof of Theorem 1.2.** For starters, we shall prove that, if $L$ is as in (i), then
\begin{equation}
u \in L^p(\Omega), \quad 0 < \mu < 1 + 1/p, \quad 1 < p < \infty, \quad Lu = 0 \text{ in } \Omega,
\end{equation}
\begin{equation}
\Rightarrow \nu \in B_{\mu-1/p}^{p,p}(\Omega) \quad \text{and} \quad \text{dist}(\cdot, \partial \Omega)^{1-\nu}|\nabla u| \in L^p(\Omega).
\end{equation}
Indeed, when $0 < \mu < 1$ this follows from Lemma 4.5 and Lemma 4.6 in [10]. Thus, it suffices to treat the case when $1/p < \mu < 1 + 1/p$. In this situation, the trace operator $\text{Tr}$ is well-defined and $\text{Tr}u \in B_{\mu-1/p}^{p,p}(\partial \Omega)$. Also, $\partial_{\nu}u \in B_{\mu-1/p-1}^{p,p}(\partial \Omega)$, where the conormal derivative is defined in the distributional sense by requiring
\begin{equation}
\langle \partial_{\nu}u, \text{Tr} \phi \rangle := \iint_{\Omega} \langle Du, D\phi \rangle, \quad \forall \phi \in \left(L_{\mu-2}^p(\Omega)\right)^{\ast}.
\end{equation}
Next, by eventually considering \( L - V \) in place of \( V \), where \( V \in C^\infty(M), V \geq 0, \) \( \text{supp } V \subseteq M \setminus \Omega \), there is no loss of generality assuming that \( L \) satisfies the following nonsingularity hypothesis
\[
(2.18) \quad \forall D \subseteq M \text{ Lipschitz, } \omega \in H^{1,2}_0(D) \text{ and } L\omega = 0 \implies \omega \equiv 0 \text{ in } D
\]
and denote by \( E(x, y) \) a fundamental solution for the operator \( L \), i.e. \( E \) is the Schwartz kernel of \( L^{-1} \). For more details, as well as an analysis of the nature of the singularity of \( E \) along the diagonal in \( M \times M \), the reader is referred to [8]. Next, let \( S, D \) stand, respectively, for the associated single and double layer potentials, i.e.
\[
(2.19) \quad Sf(x) := \int_{\partial \Omega} \langle E(x, y), f(y) \rangle \, d\sigma_y, \quad Df(x) := \int_{\partial \Omega} \langle \partial_{\nu_y} E(x, y), f(y) \rangle \, d\sigma_y, \quad x \in \Omega.
\]
Then (2.18) follows from the Green representation formula
\[
(2.20) \quad u = D(\text{Tr } u) - S(\partial_{\nu} u), \quad \text{in } \Omega,
\]
and the mapping properties of the layer potentials involved. (In the case of \( S \), (1.17) with \( \theta = 1 \) will do; thanks to the work in [10], similar results hold for \( D \).) With (2.18) at hand, the desired conclusion in Theorem 1.2 when \( L \) satisfies (i) is proved much the same as in Theorem 1.1, choosing \( \mu := s + 1/p \).

Next, turning attention to the case when \( L \) satisfies (ii) in Theorem 1.2, first observe that
\[
(2.21) \quad u \in B^{2,2}_{s+1/2}(\Omega), \quad 0 \leq s \leq 1, \quad Lu = 0 \text{ in } \Omega \implies \text{Tr } u \in B^{2,2}_{s}(\partial \Omega).
\]
Indeed, for \( 0 < s < 1 \) this is a consequence of the usual trace theorem (cf. [6] for an extension at the level of Lipschitz domains), while the endpoint cases \( s \in \{0, 1\} \) follow from the work in [8], [10].

Going further, let us assume for a moment that \( L \) satisfies the nonsingularity hypothesis (2.18) and recall the single layer potential operator \( S \). It has been proved in [8] that its boundary version, i.e. \( S := \text{Tr } S \), is invertible from \( L^2_{-\theta}(\partial \Omega) \) onto \( L^2_{-\theta}(\partial \Omega) \) for \( \theta \in \{0, 1\} \). Thus, by real interpolation,
\[
(2.22) \quad S : B^{2,q}_{-\theta}(\partial \Omega) \to B^{2,q}_{1-\theta}(\partial \Omega) \text{ is invertible for each } 0 < \theta < 1, \quad 1 < q < \infty.
\]
Also, granted the current hypotheses on \( u \), the layer potential representation
\[
(2.23) \quad u = S(S^{-1}(\text{Tr } u))
\]
holds in \( \Omega \) (cf. [3]). Now, observe that \( S^{-1}(\text{Tr } u) \in B^{2,2}_{s-1}(\partial \Omega) \) and recall from (1.17) with \( p = 2, \theta = 1 \), that
\[
(2.24) \quad S : B^{2,2}_{s-1}(\partial \Omega) \to B^{2,2}_{\gamma}(\Omega) \text{ if } (\gamma, 1/\tau) \in \Theta^d(s + 1/2, 1/2) \text{ and } 0 < s < 1.
\]
Hence, granted (2.18), the regularity statement (1.12) follows from (2.23) and (2.24). Dispensing of the extra hypothesis (2.18) can be done by working with \( L - tI \) in place of \( L \), where \( t \in \mathbb{R} \) is a sufficiently large constant, and with \( w := u + t(L - tI)^{-1}u \) in place of \( u \). The idea is that \( (L - tI)w = 0 \) and the Newtonian type potential \( (L - tI)^{-1} \) is smoothing of order 2 (cf. the discussion in [10]).
Finally, (1.13), corresponding to the limiting case when \( s \in \{0, 1\} \), follows along similar lines. This time, however, the version of (2.24) which is needed reads

\[
S : L^q_{-\theta}(\partial \Omega) \to B^{q,2}_{1-\theta+1/\mu}(\Omega)
\]

for \( 0 \leq \theta \leq 1, 1 < q \leq 2 \). This, however, is covered by (2.12).

**Proof of Theorems 1.3-1.4** These follow more or less directly from Propositions 2.1-2.3. When dealing with Theorem 1.3 one chooses \( m := \theta + N - 1 \). In the case of Theorem 1.4, one first proves the validity of the cases \( s = 0 \) and \( s = 1 \) in (1.20) \((\theta \geq 1 \text{ is only needed in the former})\) and then the desired result is obtained by interpolation.

**Acknowledgment**

I thank Ron DeVore, who first called this type of phenomenon to my attention, for several stimulating discussions.
