TWO COUNTABLY COMPACT TOPOLOGICAL GROUPS: 
ONE OF SIZE $\aleph_\omega$ AND THE OTHER OF WEIGHT $\aleph_\omega$
WITHOUT NON-TRIVIAL CONVERGENT SEQUENCES

ARTUR HIDEVUKI TOMITA

(Communicated by Alan Dow)

ABSTRACT. E. K. van Douwen asked in 1980 whether the cardinality of a
countably compact group must have uncountable cofinality in ZFC. He had
shown that this was true under GCH. We answer his question in the negative.
V. I. Malykhin and L. B. Shapiro showed in 1985 that under GCH the weight of
a pseudocompact group without non-trivial convergent sequences cannot have
countable cofinality and showed that there is a forcing model in which there
exists a pseudocompact group without non-trivial convergent sequences whose
weight is $\omega_1 < \omega$. We show that it is consistent that there exists a countably
compact group without non-trivial convergent sequences whose weight is $\aleph_\omega$.

1. Introduction

It is well-known that there is a relation between the size of an infinite compact
group $G$ and its weight, $w(G)$, given by the equality $|G| = |G|^{w(G)}$. In particular,
the cofinality of $|G|$ is uncountable. Since $\{0, 1\}^\lambda$ is a compact group for each $\lambda$,
there is a group of size $\kappa$, for $\kappa$ infinite if and only if $\kappa = 2^\mu$ for some cardinal $\mu$.

Given an infinite cardinal $\kappa$ with $\kappa = \kappa^{\omega}$, it requires only standard closing off
arguments to construct a subgroup of $\{0, 1\}^\kappa$ of size $\kappa$ which is countably compact.
It is natural to ask if those are the only possible cardinalities for infinite countably
compact groups. Its consistency was obtained by E. K. van Douwen under GCH.
Recall that, if $\kappa$ has countable cofinality, then $\kappa^{\omega} > \kappa$, but under GCH both are
equivalent.

This motivated van Douwen to ask in ZFC:

If $X$ is an infinite group (or homogeneous space) which is countably compact, is
$|X|^\omega = |X|$? Is at least $\text{cf}(|X|) \neq \omega$?

We answer his question in the negative:

Theorem 1.1. The existence of countably compact groups whose size has countable
cofinality is independent of ZFC.

Key words and phrases. Forcing, countably compact group, cofinality, weight.

This research was partially conducted while the author was visiting the Department of Math-
ematics of Universidade de Coimbra. This visit was supported by CCINT-USP and the local
organizing committee of the Fourth Ibero American Congress of Topology and its Applications.
Note that $\aleph_n$ for $n \in \omega$ cannot be the size of a counterexample to van Douwen’s question. Indeed, if there exists a countably compact group of size $\aleph_n$, then $\aleph_n \geq 2^\omega$ and therefore $(\aleph_n)^\omega = \aleph_n$.

We will show that $\aleph_\omega$ can be the size of a counterexample in a forcing model.

Sirota [\ref{s}], answering a question of Arhangelskii, constructed a pseudocompact group of weight $\tau$ without non-trivial convergent sequences of weight $\tau$, for any infinite $\tau$ satisfying $\tau = \tau^\omega$. Malykhin and Shapiro [\ref{m}] showed that under GCH, those are the only possible weights for pseudocompact groups without non-trivial convergent sequences, and using forcing they showed that there exists a pseudocompact group of weight $\aleph_1 < (\aleph_\omega)^\omega$.

However, $\omega_1$ has uncountable cofinality, thus it is natural to ask whether a pseudocompact group without non-trivial convergent sequences can have weight of countable cofinality. Also, it is natural to ask whether pseudocompactness can be replaced by countable compactness.

**Theorem 1.2.** The existence of countably compact groups without non-trivial convergent sequences whose weight has countable cofinality is independent of ZFC.

We show that it is consistent that there exists a countably compact group of size $\mathfrak{c}$ without non-trivial convergent sequences whose weight is $\aleph_\omega$.

2. A sketch of the counterexample to van Douwen’s question

Motivated by [\ref{t}], a countably compact group of size $\mathfrak{c}$ (with a non-productivity property) was constructed in [\ref{tt}] and [\ref{ttt}], as the direct sum of a countable subgroup of $2^\mathfrak{c}$ and $\bigcup_{\alpha < \mathfrak{c}} 2^\alpha \times \{0\}^{\mathfrak{c}/\alpha}$. We will obtain our example by replacing the countable group by a larger one.

**Lemma 2.1.** Let $H$ be a subgroup of $2^\mathfrak{c}$ such that for each injective sequence $\{h_n : n \in \omega\} \subseteq H$ there exists $\alpha < \mathfrak{c}$ such that $\{h_n|_{\alpha, \omega} : n \in \omega\}$ has $0 \in 2^{(\mathfrak{c}, \omega)}$ as an accumulation point. Then the group $G$ generated by $H$ and $\{x \in 2^\mathfrak{c} : (\exists \alpha < \mathfrak{c})(\{\beta \in \mathfrak{c} : x(\beta) \neq 0\} \subseteq \alpha\}$ is a countably compact group of size $|H| + 2^{\mathfrak{c}}$.

**Proof.** Let $\{y_n : n \in \omega\}$ be any sequence in the group generated. Then there exists $\{h_n : n \in \omega\} \subseteq H$ and $\alpha < \mathfrak{c}$ such that $y_n - h_n|_{\alpha, \omega} = 0 \in 2^{(\mathfrak{c}, \omega)}$. Without loss of generality, we can assume that $\{h_n : n \in \omega\}$ is either constant $h$ or injective.

In the first case, the sequence $(y_n - h)|_{\alpha}$ has an accumulation point $x \in 2^\mathfrak{c}$. Then $x \cup h|_{\alpha, \omega}$ is an accumulation point of $\{y_n : n \in \omega\}$. In the second case, by hypothesis, there exists $\beta > \alpha$ such that $\{h_n|_{\beta, \omega} : n \in \omega\}$ has $0 \in 2^{(\beta, \omega)}$ as an accumulation point. Since $2^\beta$ is compact, there exists $y \in 2^\beta$ such that $(y, 0)$ is an accumulation point of the sequence $\{(y_n|_{\beta}, h_n|_{\beta, \omega}) : n \in \omega\}$. Therefore, $y \cup 0|_{\beta, \omega}$ is an accumulation point of $\{y_n : n \in \omega\}$.

Clearly the size of the second group is $2^{\mathfrak{c}}$, therefore the size of the group generated is $|H| + 2^{\mathfrak{c}}$. \hfill \square

We observe that the construction of a group $H$ of size $\kappa \leq \mathfrak{c}$ can be done using Martin’s Axiom for partial orders of size $\kappa$, but for one of size $\aleph_\omega > \mathfrak{c}$, it is not enough. Indeed, GCH implies MA and van Douwen showed that this implies the non-existence of $\aleph_\omega$-sized countably compact groups. The forcing model in which a group $H$ of size $\aleph_\omega$ exists will be described in the following section:
Theorem 2.2. Given a model of CH and a regular cardinal κ > ω, there exists a countably closed, 2-cc forcing such that, in the extension, for every cardinal λ ∈ [κ, κ] there exists a countably compact group of size λ.

In particular, we obtain the example in the title.

Example 2.3. It is consistent that κ = ℵ₁ < ℵ₂ and there exists a group of size ℵ₂ that is countably compact.

Start with a model of GCH and apply Theorem 2.2 for the cardinal (ℵ₂)⁺ in the ground model. Let λ = ℵ₂. Since CH holds and the forcing is countably closed, CH holds in the extension. Furthermore, the forcing is cardinal preserving, therefore, ℵ₂ in the extension is λ. Thus, there is a countably compact group of size ℵ₂ in the extension.

3. THE FORCING

Assume CH and let κ be a regular cardinal greater than ω₁. Let {fξ : ξ ∈ κ} be an enumeration of all 1-1 sequences in [κ]^{<ω}.

Throughout this construction, we shall denote z_F = ∑_{μ ∈ F} z_μ whenever F is a finite set of indexes and {z_μ : μ ∈ F} is a family of functions from a fixed ordinal into 2.

Definition 3.1. We say that p = (α_p, {x_β^n : η ∈ E_β}, {A_β^n : δ ∈ D_β}) is an element of P if α_p ∈ ω₁, D_β, E_β ∈ [κ]^{ω}, E_β = D_β ∪ ∪_{n∈ω∧δ∈D_β} f_δ(η), x_β^n ∈ 2^α_p for each η ∈ E_β and A_β^n ∈ [ω]^{<ω} for each δ ∈ D_β. Given p, q ∈ P, we say that p ≤ q if α_p ≥ α_q, D_β ≥ D_q, E_β ≥ E_q, ∀η ∈ E_q(x_η^n|α_q = x_η^n), ∀δ ∈ D_q(A_β^n ⊆* A_q^n) and the sequence {x_β^n||α_q, α_p) : n ∈ A_β^n} converges to 0||α_q, α_p) ∈ 2^{[α_q, α_p]} for every δ ∈ D_q.

Lemma 3.2. The set P endowed with the partial ordering above is countably closed and 2-cc.

Proof. Given a decreasing sequence {p_n : n ∈ ω} with p_n = (α_n, {x_β^n : η ∈ E_β}, {A_β^n : δ ∈ D_β}), let p_ω = (α_ω, {x_β^{ω} : η ∈ E_ω}, {A_β^{ω} : δ ∈ D_ω}), where α_ω = ∪_{n∈ω} α_n, D_ω = ∪_{n∈ω} D_n, E_ω = ∪_{n∈ω} E_n, x_β^{ω} = ∪_{n∈ω∧η∈E_n} x_β^n, and A_β^{ω} is an infinite subset of ω such that for each δ ∈ D_ω, A_β^{ω} ⊆* A_β^n for each n ∈ ω such that δ ∈ D_n. Clearly p_ω ∈ P and p_n ≤ p_ω for each n ∈ ω. Hence, P is countably closed.

Let {p_μ : μ < ω_2} be a subset of P. Using the ∆-system lemma, there exists E ∈ [κ]^{<ω} and I ∈ [ω_2]^{<ω} such that E_μ ∩ E_β = E for any pair {μ, β} ∈ |I|^2. We can also assume that there exists α ∈ ω₁ such that α_μ = α for every μ ∈ I. Furthermore, there are only ω₁ functions from E to 2^α and there are only ω₁ functions from E to [ω_2]^{<ω}, thus, we can assume that for every pair {μ, β} ∈ |I|^2, x_β^{ω} = x_β^{μ} for every η ∈ E and E_β = A_β^{ω} = A_β^{μ} for every δ ∈ D_μ ∩ D_β ⊆ E.

Fix μ, β ∈ I distinct and let p = (α, {x_η^n : η ∈ E_μ} ∪ {x_η^n : η ∈ E_β \ E}, {A_β^n : δ ∈ D_μ} ∪ {A_δ^n : δ ∈ D_β \ D_μ}). Then p ≤ p_β and p ≤ p_μ. Therefore, P has the 2-cc property.

We define now some dense subsets of P.

Definition 3.3. Let φ : F → 2, where F ∈ [κ]^{<ω} and α ∈ ω₁. Define D_{φ, α} = {p ∈ P : dom φ ⊆ D_φ ∧ (∃γ ∈ [α, α_p) ∀ξ ∈ dom φ (φ(ξ) = x_ξ^n(γ)))}. 
Lemma 3.4. The sets defined in Definition 3.3 are dense in $\mathbb{P}$.

The proof of the density of the sets above will be given later in this section. We will first prove the main theorem.

Proof of Theorem 2.2. Assume $CH$, let $\kappa > \epsilon$ be a regular cardinal and let $\mathbb{P}$ be the partial order defined in Definition 3.1. From Lemma 3.2 this partial ordering is countably closed and $\omega_2$-cc. Let $\mathcal{G}$ be a generic filter for the partial order $\mathbb{P}$ which intersects each dense set in Definition 3.3. For each $\xi \in \kappa$, let $x_\xi = \bigcup_{p \in \mathcal{G} \cap \xi \in D_p} x_\xi^p$.

Let $\phi$ be the function of domain $\{\xi\}$ such that $\phi(\xi) = 0$. For every $\alpha < \omega_1$ there exists $p \in \mathcal{G} \cap D_{\phi,\alpha}$ such that $\alpha_p > \alpha$ and $\xi \in D_p$. Therefore, $x_\xi \in 2^{\omega_1}$.

We claim that $\{x_\xi : \xi < \kappa\}$ is linearly independent. Indeed, if $F$ is a non-empty finite subset of $\kappa$, there exist $\phi : F \longrightarrow 2$ such that $\sum_{\mu \in F} \phi(\mu) \neq 0$ and $p \in \mathcal{G} \cap D_{\phi,\omega}$. Then, there exists $\gamma < \alpha_p$ such that $x_F(\gamma) = x_F^p(\gamma) = \sum_{\mu \in F} \phi(\mu) \neq 0$. Thus, $x_F \neq 0 \in 2^{\omega_1}$.

Let $I$ be a subset of $\kappa$. We claim that the group $H_I$ generated by $\{x_\xi : \xi \in I\}$ satisfies the conditions of Lemma 2.1. Indeed, let $\{y_n : n \in \omega\}$ be an injective sequence in $H_I$. There exists a function $f : \omega \longrightarrow [I]^{<\omega}$ such that $y_n = x_{f(n)}$ for each $n \in \omega$. Since the forcing does not add new countable subsets of the ground model, there exists $\zeta < \kappa$ such that $f = f_\zeta$. Let $p \in \mathcal{G}$ such that $\xi \in D_p$. If $F$ is a finite subset of $[\alpha_p, \omega_1)$, then there exists $q \in \mathcal{G}$ such that $\alpha_q > \max F$ and $q \leq p$. Thus, $\{n \in \omega : y_n \in x_F = 0\}$ has $0 \in 2^{\omega_1}$ as an accumulation point and $H_I$ satisfies the conditions of Lemma 2.1.

As $H_I$ is a group with a basis of size $I$, we conclude that $H_I$ and $I$ have the same size if $I$ is infinite. Thus applying Lemma 2.1 we obtain countably compact groups of any size between $\kappa$ and $\epsilon$.

We will be done by proving the density of the sets in Definition 3.3.

Proof of Lemma 3.4. Let $q$ be an arbitrary element of $\mathbb{P}$ and fix $\phi : F \longrightarrow 2$, with $F \in [\kappa]^{<\omega}$ and $\alpha < \omega_1$. Define $\alpha_r = \max\{\alpha, \alpha_q\}$, $D_r = D_q \cup \text{dom } \phi$, $E_r = D_r \cup \bigcup_{n \in \omega, \delta \in D_r} f_\delta(n)$.

For each $\eta \in E_r \setminus E_q$ define $x^{\eta}_r = 0 \in 2^{\omega_1}$; for each $\eta \in E_q$ define $x^{\eta}_r = x^{\eta}_q \cup 0[\alpha_q, \omega_1)$. For each $\delta \in D_r \setminus D_q$ define $A^\delta_r = \omega$ and for each $\delta \in D_q$ define $A^\delta_r = A^\delta_q$. Clearly $r = (\alpha_r, \{x^\eta_r \in E_r\}, \{A^\delta_r : \delta \in D_r\}) \leq q$. We shall extend $r$ to some $p \in D_{\phi,\alpha}$ with $\alpha_p = \alpha_r + 1$, $D_p = D_r$, $E_p = E_r$. We will define a function $\psi : E_p \longrightarrow 2$ which will be used to define each $x^\mu_p(\alpha_r)$. Enumerate $D_p$ as $\{\beta_n : n \in \omega\}$ such that each element of $D_p$ appears infinitely often in the enumeration. Set $F_0 = \text{dom } \phi$ and let $\psi|F_0 = \phi$. We shall define $\psi|F_n$ and $k_n$ by induction such that $F_n \cup f_{\beta_n}(k_n) \subseteq F_{n+1}$, $k_n \in A^\beta_{k_n}$, $k_n < k_{n+1}$, and $\sum_{\mu \in f_{\beta_n}(k_n)} \psi(\mu) = 0$.

Suppose that $F_n$, $\psi|F_n$ and $k_{n-1}$ are defined for each $n \leq m$ satisfying the inductive hypothesis. Let $k_n > k_{n-1}$ such that $k_n \in A^p_m$ and $f_{\beta_n}(k_m) \setminus F_m \neq \emptyset$. Set $F_{m+1} = F_m \cup f_{\beta_n}(k_m)$ and define $\psi$ on $F_{m+1} \setminus F_m$ so that $\sum_{\mu \in f_{\beta_n}(k_m)} \psi(\mu) = 0$. At stage $\omega$, $\psi$ is defined on $F = \bigcup_{n \in \omega} F_n$. Define $\psi(\mu) = 0$ for each $\mu \in E_p \setminus F$. Let $x^\mu_r = x^\mu_q \cup \{(\alpha_r, \psi(\eta))\}$ for each $\eta \in E_p$ and $A^\mu_r = \{\beta_n : \beta_n \in A^\mu_q\}$ for each $\mu \in D_p$. It is easy to see that $p \leq r$ and $p \in D_{\phi,\alpha}$. Thus, $D_{\phi,\alpha}$ is dense in $\mathbb{P}$.

4. Countably compact groups without non-trivial convergent sequences whose weight is \( \aleph_\omega \)

The next theorem shows how to increase the weight of countably compact groups without non-trivial convergent sequences of size \( \aleph \).

**Theorem 4.1.** If there exists an infinite countably compact group topology without non-trivial convergent sequences on a free Abelian group \( G \), then there exists a countably compact group topology without non-trivial convergent sequences of size \( \aleph \) whose weight is \( \kappa \), for any \( \kappa \in [\aleph, 2^\aleph] \).

As a corollary to the proof of Theorem 4.1, we have the following:

**Theorem 4.2.** If there exists an infinite countably compact group topology without non-trivial convergent sequences on an Abelian group \( G \), then there exists a countably compact group topology without non-trivial convergent sequences of size \( \aleph \) and weight \( \kappa \), for any \( \kappa \in [\aleph, 2^\aleph] \).

Allowing convergent sequences, van Douwen \[3\] and Comfort and Remus \[1\] have obtained countably compact groups whose weight has countable cofinality in ZFC. It is still open if there are countably compact groups without non-trivial convergent sequences in ZFC (this has been asked by van Douwen in \[2\]).

**Example 4.3.** If \( \text{MA}_{\text{countable}} \) holds and \( \epsilon \leq \aleph_\omega \leq 2^\epsilon \), then there exists a countably compact group topology without non-trivial convergent sequences of weight \( \aleph_\omega \) on the free Abelian group of size \( \epsilon \).

From \[3\], there exists, under \( \text{MA}_{\text{countable}} \), a countably compact group topology without non-trivial convergent sequences of weight \( \epsilon \) on the free Abelian group of size \( \epsilon \). Applying Theorem 4.1, there exists one of size \( \aleph_\omega \), as \( \epsilon < \aleph_\omega < 2^\epsilon \).

**Proof of Theorem 4.1.** By standard closing off arguments and from the fact that subgroups of free Abelian groups are free Abelian, we can assume that \( G \) has cardinality \( \alpha \). Since \( G \) is Abelian and countably compact, we can assume that it is a subgroup of \( T^\lambda \) for some cardinal \( \lambda \). There are only \( \alpha \) many sequences and finite sums of elements of \( G \); thus, we can project \( G \) injectively into \( T^\theta \), with \( \theta \leq \epsilon \) so that its projection is free Abelian and does not contain non-trivial convergent sequences. Therefore, we can assume that the weight of \( G \) is at most \( \alpha \).

Let \( \{ y_\xi : \xi < \epsilon \} \) be an independent set of generators for \( G \).

Let \( I \) be the set of all even ordinals in \( \epsilon \). Fix an enumeration \( \{ f_\xi : \xi \in I \} \) of all injective functions \( f \) such that \( \text{dom} f = \omega \), \( \text{dom} f(n) \in [\epsilon]^{\omega} \setminus \{ \emptyset \} \) and \( \text{rng} f(n) \subseteq Z \setminus \{ 0 \} \) for every \( n \in \omega \). Furthermore, let \( \bigcup_{\xi \in \omega} \text{dom} f_\xi(n) \subseteq [\xi] \) for every \( \xi \in I \).

In this construction, we denote \( x_{f(n)} = \sum_{\mu \in \text{dom} f(n)} f(n)(\mu)x_\mu \).

By induction, suppose that for \( \mu < \xi < \epsilon \), we have chosen \( x_\mu \in G \) satisfying the following:

(i) \( \{ x_\beta : \beta < \mu \} \) is independent for every \( \mu < \xi \) and

(ii) if \( \mu \in I \), then \( x_\mu \) is an accumulation point of the sequence \( \{ x_{f_\mu(n)} : n \in \omega \} \).

We will show that \( x_\xi \) can be chosen so that the inductive hypothesis is satisfied. Indeed, let \( H \) be the subgroup generated by \( \{ x_\beta : \beta < \xi \} \). For each \( h \in H \) let \( J_h \) be a finite subset of \( \epsilon \) such that \( h \in \{ y_\beta : \beta \in J_h \} \). Let \( J = \bigcup_{h \in H} J_h \) and choose \( x_\xi \in G \setminus \{ y_\beta : \beta \in J \} \) if \( \xi \) is odd or \( x_\xi \in \{ x_{f_\xi(n)} : n \in \omega \} \setminus \{ y_\beta : \beta \in J \} \) if \( \xi \) is even. Note that the last difference is non-empty since the first set has size \( \epsilon \) and the second set has size less than \( \epsilon \). Clearly \( x_\xi \) satisfies the inductive hypothesis.
Let \( p_\xi \) be an ultrafilter on \( \omega \) such that \( x_\xi \) is the \( p_\xi \)-limit of the sequence \( \{ x_{f_\xi(n)} : n \in \omega \} \).

Fix \( \kappa \in [\theta, 2^\theta] \). Let \( \{ z_\xi : \xi \in c \setminus I \} \) be a dense subset of \( T^\kappa \). By induction on \( \mu \in I \), let \( z_\mu \) be the \( p_\mu \)-limit of \( \{ z_{f_\mu(n)} : n \in \omega \} \). The group generated by \( \{(x_\xi, z_\xi) : \xi < \kappa\} \subseteq G \times T^\kappa \) is as required. \( \square \)

Using an argument similar to the one in Theorem 4.1 on the second example in [6], we can obtain the following example:

**Example 4.4.** It is consistent with CH that there exists a free Abelian group of size \( 2^\theta \) and weight \( \kappa \) for each \( \kappa \) in \( [\theta, 2^\theta] \) and \( 2^\theta \) can be arbitrarily large. In particular, it is consistent that there exists a countably compact free Abelian group of weight \( \lambda > 2^\theta \), with \( \lambda \) of countable cofinality.

**Note.** The author and I. Castro Pereira modified [6] to obtain a group in Theorem 2.2 that is free Abelian and without non-trivial convergent sequences.

---

**ACKNOWLEDGMENT**

It is a pleasure to thank P. Koszmider for some comments concerning this paper and Professor Comfort for information concerning the references. I also thank the Topology Seminar at Morelia to whom I presented a draft of the paper.

The author is grateful to the referee for a careful reading of the paper. All his suggestions make the notation more consistent and the reading of the same more pleasant. Future papers of the author should benefit from the referee’s TeX advice.
