SINGLE ELEMENTS AND MODULE ISOMORPHISMS
OF SOME OPERATOR ALGEBRA MODULES

DONG ZHE

(Communicated by David R. Larson)

ABSTRACT. In this paper, we first introduce the concept of single elements in a module. A systematic study of single elements in the $\mathcal{A}_L$-module $U$ is initiated, where $L$ is a completely distributive subspace lattice on a Hilbert space $H$. Furthermore, as an application of single elements, we study module isomorphisms between norm closed $\mathcal{A}_N$-modules, where $N$ is a nest, and obtain the following result: Suppose that $U, V$ are norm closed $\mathcal{A}_N$-modules and that $\Phi : U \rightarrow V$ is a module isomorphism. Then $U = V$ and there exists a non-zero complex number $\lambda$ such that $\Phi(T) = \lambda T, \forall T \in U$.

1. Introduction and preliminaries

An element $S$ of an algebra $A$ is called single if the condition $AB = 0$ for $A, B$ in $A$ implies $AS = 0$ or $SB = 0$. It is easy to show that a rank one operator is a single element of any operator algebra containing it. It is primarily for this reason that the notion of ‘single element’ plays a role in the representation theory of $C^*$-algebras or, more generally, of semi-simple Banach algebras ([2], [3]). In yet another aspect, namely in the study of algebraic isomorphisms between reflexive operator algebras on a normed space, single elements have also proved a useful tool. This is mainly because single elements are carried to single elements under algebraic isomorphisms. So if, in a particular operator algebra, it is shown that each single element is of rank one (the converse is always true), then the study of algebraic isomorphism is considerably simplified. Reflexive algebras that have been looked at from this point of view include nest algebras on a Hilbert space [9] and algebras of operators leaving invariant the elements of a complete atomic Boolean lattice of subspaces on normed space [5]. On each of the two above-mentioned operator algebras, it is proved in [5], [9] that single elements are of rank one. Using this, one shows that each algebraic isomorphism between a pair of such algebras is automatically continuous and spatial in the sense that it is of the form $\Phi(A) = T^{-1}AT$ for suitable $T$ ([5], [9]).

A systematic study of single elements of a reflexive operator algebra $\mathcal{A}_L$, where $L$ is completely distributive, was initiated by Lambrou in [6]. Amongst many other interesting results, he shows that single elements of any rank (including infinity)
are possible. In [8], Longstaff and Penaia obtained a lattice-theoretic condition for the existence of a single element of rank \( n \) (or infinity).

**Definition 1.1.** Let \( \mathcal{R} \) be a ring and \( \mathcal{M} \) a \( \mathcal{R} \)-bimodule. An element \( s \) in \( \mathcal{M} \) is called single if, whenever \( asb = 0 \) with \( a, b \in \mathcal{R} \), then \( as = 0 \) or \( sb = 0 \).

Though this is a simple generalization of the notion of single elements in algebras, we hope that as single elements in algebras, single elements in modules will play a role in the representation theory of modules, and in the study of module isomorphisms between modules, especially in operator module theory. In Section 2 of this paper, we initiate the study of single elements in Alg\( \mathcal{L} \)-modules, where \( \mathcal{L} \) is a completely distributive subspace lattice on a Hilbert space \( \mathcal{H} \), and we obtain some elementary properties of single elements in Alg\( \mathcal{L} \)-modules. As a corollary, we show that every single element of nest algebra modules is of rank one. In Section 3, using single elements of nest algebra modules, we completely solve the problem of module isomorphisms between norm closed nest algebra modules. It turns out that such isomorphisms are necessarily trivial.

Let us introduce some notation and terminology. \( \mathcal{H} \) represents a complex separable infinite-dimensional Hilbert space, and \( B(\mathcal{H}) \) the algebra of all bounded operators on \( \mathcal{H} \). The term ‘subspace’ of \( \mathcal{H} \) shall mean a closed linear manifold of \( \mathcal{H} \). A collection \( \mathcal{L} \) of subspaces of \( \mathcal{H} \) is called a subspace lattice on \( \mathcal{H} \) if it contains \((0)\) and \( \mathcal{H} \), and is closed under the formation of arbitrary closed linear spans (denoted ‘\( \bigvee \)’) and intersection (denoted ‘\( \bigwedge \)’). If in a subspace lattice \( \mathcal{L} \) the infinite distributive identity

\[
\bigwedge \bigvee
\bigwedge_{a \in A} b_{a} = \bigvee_{f \in B^{*}} \bigwedge_{a \in A} L_{a, f(a)}
\]

and its dual holds, \( \mathcal{L} \) is called completely distributive. The formal definition of complete distributivity just given is in practice and difficult to use. Alternative characterizations of complete distributivity have been proven to be more useful.

**Lemma 1.1 (17).** For a subspace lattice \( \mathcal{L} \), the following are equivalent:

1. \( \mathcal{L} \) is completely distributive;
2. \( L = \bigcap \{ K_{-} : K \in \mathcal{L}, K \not\supseteq L \} \), for every \( L \in \mathcal{L} \);
3. \( L = \bigvee \{ K \in \mathcal{L} : K \not\supseteq L \} \), for every \( L \in \mathcal{L} \); here \( K_{-} = \bigvee \{ G \in \mathcal{L} : G \not\supseteq K \} \).

It follows from Lemma 1.1(3) that the linear manifold \( \mathcal{H}_{0} = \text{span} \{ K \in \mathcal{L} : K \neq (0), K_{-} \neq \emptyset \} \) is norm dense in \( \mathcal{H} \). Similarly, Lemma 1.1(2) shows that \( \mathcal{H}_{1} = \text{span} \{ K_{=} : K \neq (0), K_{-} \neq \emptyset \} \) is also norm dense in \( \mathcal{H} \).

If \( \mathcal{L} \) is a subspace lattice, Alg\( \mathcal{L} \) denotes the set of operators on \( \mathcal{H} \) leaving every member of \( \mathcal{L} \) invariant. Obviously, Alg\( \mathcal{L} \) is a unital Banach algebra. Operator algebras of the type Alg\( \mathcal{L} \) are called reflexive operator algebras. A nest \( \mathcal{L} \) is a totally ordered subspace lattice, and Alg\( \mathcal{L} \) is called the nest algebra associated with the nest \( \mathcal{L} \).

If \( x \) and \( y \) are non-zero vectors in \( \mathcal{H} \), we define the rank one operator \( x \otimes y \) by

\[
(x \otimes y)(z) = (z, y) x, \quad \forall z \in \mathcal{H}.
\]

**Lemma 1.2 (17).** If \( \mathcal{L} \) is a subspace lattice, then the rank one operator \( x \otimes y \) belongs to Alg\( \mathcal{L} \) if and only if there is an element \( L \in \mathcal{L} \) such that \( x \in L \) and \( y \in L_{=}^{\perp} \), where \( L_{=} = \bigvee \{ K \in \mathcal{L} : K \not\supseteq L \} \).
Definition 1.2. Let \( \mathcal{L} \) be a subspace lattice and let \( \mathcal{U}, \mathcal{V} \) be \( \text{Alg}\mathcal{L} \)-bimodules. A module homomorphism \( \Phi \) from \( \mathcal{U} \) to \( \mathcal{V} \) is a linear map \( \Phi : \mathcal{U} \to \mathcal{V} \) such that
\[
\Phi(ABT) = A\Phi(T)B, \quad \forall A, B \in \text{Alg}\mathcal{L}, T \in \mathcal{U}.
\]
Furthermore, if \( \Phi \) is a bijection, we shall say that \( \Phi \) is a module isomorphism.

In Section 3 of this paper, we will investigate the problem of the module isomorphism between norm closed nest algebra modules. The terminology and notation concerning nest algebra modules may be found in \([4]\).

2. Single elements in \( \text{Alg}\mathcal{L} \)-modules

Lemma 2.1. Let \( \mathcal{L} \) be a completely distributive subspace lattice on \( \mathcal{H} \), and let \( A \in \mathcal{B}(\mathcal{H}) \).

(1) If \( RA = 0 \) for all rank one operators \( R \in \text{Alg}\mathcal{L} \), then \( A = 0 \).

(2) If \( AR = 0 \) for all rank one operators \( R \in \text{Alg}\mathcal{L} \), then \( A = 0 \).

Proof. (1) If \( R \in \text{Alg}\mathcal{L} \) is of rank one, then \( R = x \otimes y \), where \( y \in K^1 \) for some \( K \in \mathcal{L} \). The condition \( 0 = (x \otimes y)A = x \otimes A^*y \) for all rank ones of \( \text{Alg}\mathcal{L} \) implies \( \ker A^* \supseteq K^1 \), so taking the linear span over all such \( K \), we have \( \ker A^* \supseteq \mathcal{H}_1 \), where \( \mathcal{H}_1 \) is as defined just below the statement of Lemma 1.1. The continuity of \( A^* \) and the norm density of \( \mathcal{H}_1 \) implies that \( A^* \), and hence \( A \), is zero.

(2) The condition \( 0 = A(x \otimes y) = Ax \otimes y \) implies \( \ker A \supseteq K \) for each \( K \) with \( K_\perp \neq \mathcal{H} \). So \( \ker A \supseteq \mathcal{H}_0 \), which is norm dense in \( \mathcal{H} \), and so \( A \) is zero. \( \square \)

Lemma 2.2. Let \( \mathcal{L} \) be a complete distributive subspace lattice and \( \mathcal{U} \) an \( \text{Alg}\mathcal{L} \)-module. Then an element \( S \) of \( \mathcal{U} \) is single if and only if for each rank one operator \( R_1, R_2 \) of \( \text{Alg}\mathcal{L} \), the condition \( R_1SR_2 = 0 \) implies that \( R_1S \) or \( SR_2 \) is zero.

Proof. If \( S \) is single, then the above condition is only a special case of the definition. Suppose that \( ASB = 0 \) for \( A, B \in \text{Alg}\mathcal{L} \). If \( SB \neq 0 \), then by Lemma 2.1 there exists a rank one operator \( R_2 \) of \( \text{Alg}\mathcal{L} \) such that \( SRB_2 = 0 \). For any rank one \( R_1 \) of \( \text{Alg}\mathcal{L} \), we have \( R_1ASBR_2 = 0 \), and clearly \( R_1A \) and \( BR_2 \) are of rank one or zero. In either case the condition in the lemma implies \( R_1AS \) or \( SR_2 \) is zero. But as \( SRB_2 \neq 0 \), we have for all rank one operators \( R_1 \) of \( \text{Alg}\mathcal{L} \) that \( R_1AS \) is zero. Applying Lemma 2.1 once again, it follows that \( AS = 0 \), and this shows that \( S \) is a single element of \( \mathcal{U} \). \( \square \)

Lemma 2.3. Let \( \mathcal{L} \) be a completely distributive subspace lattice, \( \mathcal{U} \) an \( \text{Alg}\mathcal{L} \)-module, and \( S \) a single element of \( \mathcal{U} \). Then there exists an \( M \) in \( \mathcal{L} \) with \( M_\perp \neq \mathcal{H} \) such that \( S|_M \) is non-zero. Moreover, for any \( L \in \mathcal{L} \) with \( L_\perp \neq \mathcal{H} \) and \( S|_L \) non-zero, the operator \( S|_L \) is of rank one.

Proof. By Lemma 2.1 there is a rank one operator \( R \in \text{Alg}\mathcal{L} \) such that \( SR \neq 0 \). By Lemma 2.2 \( R \) is of the form \( x \otimes y \) where \( x \in M, y \in M_\perp \) for some \( M \in \mathcal{L} \) and \( M_\perp \neq \mathcal{H} \). But then \( 0 \neq S(x \otimes y) = Sx \otimes y \) shows that \( Sx \neq 0 \), and the first part of the lemma is proved.

By Lemma 2.1 there is a rank one \( T \in \text{Alg}\mathcal{L} \) such that \( TS \neq 0 \). Now let \( L \in \mathcal{L} \) satisfy the condition in the statement of the lemma. We are to prove that if \( x, y \in L \), then \( Sx \) and \( Sy \) are linearly dependent, so there is no loss in assuming that \( Sx, Sy \) are non-zero.
The operator $TS$ is of rank one, so there exist scalars $\lambda, \mu$ not both zero, such that $TS(\lambda x + \mu y) = \lambda(TSx) + \mu(TSy) = 0$. For any non-zero $z \in L^\perp$, we have $(\lambda x + \mu y) \otimes z \in \text{Alg}L$ and

$$TS[(\lambda x + \mu y) \otimes z] = TS(\lambda x + \mu y) \otimes z = 0.$$  

However, $S$ is single and $TS \neq 0$, so

$$S(\lambda x + \mu y) \otimes z = S[(\lambda x + \mu y) \otimes z] = 0,$$

which in turn implies $\lambda(Sx) + \mu(Sy) = 0$, and so $Sx, Sy$ are linearly dependent. Thus the operator $S|_L$ is of rank one. \hfill \Box

Suppose that $\mathcal{L}$ is a completely distributive subspace lattice; for any $L \in \mathcal{L}$ we set $\tau(L) = [UL]$. Since $\mathcal{L}$ is completely distributive, by virtue of Lemma [11] and Lemma [12] we can easily show that $\mathcal{L} = \text{LatAlg}L$. Thus $\tau(L) = [UL] \in \text{LatAlg}L = \mathcal{L}$, and $\tau$ is an order homomorphism from $\mathcal{L}$ into itself. Define

$$U_r = \{T \in B(H) : TL \subseteq \tau(L), \forall L \in \mathcal{L}\}.$$  

Clearly $U_r \supseteq U$ and $U_r$ is a weakly closed Alg$\mathcal{L}$-module.

**Proposition 2.1.** Let $\mathcal{L}$ be a completely distributive subspace lattice, $U$ an Alg$\mathcal{L}$-module and $S$ a non-zero single element of $U$. If $S|_M$ non-zero for an $M \in \mathcal{L}$ with $M^- \neq \mathcal{H}$, then $S(H) \subseteq \tau(M) = [UM]$.

**Proof.** Let $L \in \mathcal{L}$ with $L \nsubseteq \tau(M)$. We shall first show that $S(H) \subseteq L^-$. If $L = H$ we have nothing to prove, so assume $L \neq H$. The condition $L \nsubseteq \tau(M)$ implies $\tau(M) \subseteq L^-$, so if $m \in M$, it follows from $S \in U \subseteq U_r$ that

$$Sm \in S(M) \subseteq \tau(M) \subseteq L^-.$$  

Now let $y \in L^\perp$ be arbitrary. Choose non-zero $x \in L$ and $m \in M$ with $Sm \neq 0$ and non-zero $l \in M^\perp$. Then by Lemma [12] the rank one $x \otimes y$ and $m \otimes l$ belong to Alg$\mathcal{L}$, and $S(m \otimes l) \neq 0$. However, $Sm \in L^-$ and $y \in L^\perp$, so

$$(x \otimes y)S(m \otimes l) = (x \otimes y)(Sm \otimes l) = (Sm, y)x \otimes l = 0.$$  

The assumption that $S$ is single implies $(x \otimes y)S = 0$. Thus for any $h \in H$, we have

$$(x \otimes y)Sh = (Sh, y)x = 0,$$

and so $(Sh, y) = 0$ for any $y \in L^\perp$. This shows that $Sh \in L^-$ and $S(H) \subseteq L^-$, as required.

Since $\mathcal{L}$ is completely distributive, it follows from Lemma [13] that $\tau(M) = \bigcap\{L^- : L \in \mathcal{L}, L \nsubseteq \tau(M)\}$. Hence $S(H) \subseteq \bigcap\{L^- : L \in \mathcal{L}, L \nsubseteq \tau(M)\} = \tau(M)$. \hfill \Box

For an Alg$\mathcal{L}$-module $U$, we define

$$\mathcal{T}_r = \{T \in B(H) : T\tau(L) \subseteq L, \forall L \in \mathcal{L}\}.$$  

**Theorem 2.1.** Let $\mathcal{L}$ be a completely distributive subspace lattice and $U$ an Alg$\mathcal{L}$-module. If $S$ is a single element of $U$ with $S\mathcal{T}_r S \neq 0$, then $S$ is of rank one.

**Proof.** Let $A \in \mathcal{U}_r$ be such that $SAS \neq 0$, and let $l_2$ be such that $SASl_2 \neq 0$. Put $l_1 = ASl_2$ and $l = Sl_1$. We will show that $S(H) \subseteq Cl$. First we show that if $K \in \mathcal{L}$ with $K^- \neq \mathcal{H}$, then $S(K) \subseteq Cl$. Indeed if $S(K) = \{0\}$ we have nothing to prove. If instead $S(K) \neq \{0\}$, Proposition 2.1 implies that $S(H) \subseteq \tau(K)$. But then $l_1 = ASl_2 \in A(\tau(K)) \subseteq K$, since $A \in \mathcal{U}_r$. Note that $S|_K$ is non-zero, since $l_1 \in K$ and $Sl_1 = SASl_2 \neq 0$; thus Lemma [2,3] implies $S|_K$ is of rank one.
Hence $S(K) \subseteq \mathcal{C}S\mathcal{l} = \mathcal{C}l$, as claimed. Now denoting by $\mathcal{H}_0$ the linear span of \{ $K \in \mathcal{L} : K \neq (0), K \subseteq \mathcal{H}$\}, the above also shows that $S(\mathcal{H}_0) \subseteq \mathcal{C}l$. But it follows from Lemma 1.1 that $\mathcal{H}_0$ is dense in $\mathcal{H}$, so

$$S(\mathcal{H}) = S(\mathcal{H}_0) \subseteq \overline{S(\mathcal{H}_0)} \subseteq \overline{\mathcal{C}l} = \mathcal{C}l.$$ 

This completes the proof. \hfill $\square$

Obviously, nests are completely distributive, so the results in the section also hold for nests.

**Corollary 2.1.** If $\mathcal{L}$ is a nest and $\mathcal{U}$ is an Alg$\mathcal{L}$-module, then every non-zero single element of $\mathcal{U}$ is of rank one, and conversely.

**Proof.** Let $S$ be a single element of Alg$\mathcal{L}$. By Lemma 2.3 that there exists an $L$ in $\mathcal{L}$ such that $S(L)$ is one dimensional. Let $M \in \mathcal{L}$, $M \neq \mathcal{H}$ with $M \supseteq L$. Since $S(M)$ is non-zero, it follows from Lemma 2.3 again that $S(M)$ is also one dimensional. Clearly the one-dimensional subspaces $S(M), S(L)$ coincide, as $L \subseteq M$. Now, by the total order of $\mathcal{L}$, the set $\mathcal{H}_0 = \bigcup\{ M \in \mathcal{L} : M \neq \mathcal{H}, M \supseteq L \}$ is a dense linear manifold, and by the above $S(\mathcal{H}_0)$ is one dimensional, thus $S(\mathcal{H}_0) = \mathcal{C}l$ for some non-zero vector $l \in \mathcal{H}$. Hence, $S(\mathcal{H}) = \mathcal{C}l$ and $S$ is of rank one. \hfill $\square$

### 3. Module isomorphisms

In this section, we are concerned with the problem of module isomorphisms between nest algebra modules. Since one feels that non-norm-closed nest algebra modules are rather pathological and that the proper objects for study should at least be complete, we only concern ourselves with norm closed nest algebra modules. In this section, we adopt the terminology and notation in [4]. $\mathcal{N}$ always represents a nest on $\mathcal{H}$, and $\mathcal{U}$ is a norm closed Alg$\mathcal{N}$-module. In the following, we set $\tau(\mathcal{N}) = \widetilde{\mathcal{N}} = [\mathcal{U}\mathcal{N}]$ for any $\mathcal{N} \in \mathcal{N}$ and $\mathcal{U}_r = \{ T \in \mathcal{B}(\mathcal{H}) : TN \subseteq \widetilde{\mathcal{N}}, \forall N \in \mathcal{N} \}$.

**Lemma 3.1.** Suppose that $\mathcal{U}, \mathcal{V}$ are norm closed Alg$\mathcal{N}$-modules, and that $\Phi : \mathcal{U} \to \mathcal{V}$ is a module isomorphism. Then $\Phi$ preserves rank one operators; furthermore, $\Phi$ preserves rank.

**Proof.** Let $T \in \mathcal{U}$ have rank one. It follows from Corollary 2.1 that we only need to show that $\Phi(T)$ is a single element of $\mathcal{V}$. Let $A, B \in \text{Alg}\mathcal{N}$ with $A\Phi(T)B = 0$. Since $0 = A\Phi(T)B = \Phi(ATB)$ and $\Phi$ is a module isomorphism, it follows that $ATB = 0$. Since $T$ is of rank one, at least one of $AT, TB$ is zero. Thus, it follows from $A\Phi(T) = \Phi(AT)$ and $\Phi(T)B = \Phi(TB)$ that at least one of $A\Phi(T), \Phi(T)B$ is zero. Therefore $\Phi(T)$ is single in $\mathcal{V}$ and from Corollary 2.1, $\Phi(T) \in \mathcal{V}$ is a rank one operator.

Set $\tau(\mathcal{N}) = [\mathcal{U}\mathcal{N}] = \widetilde{\mathcal{N}}$ for every $\mathcal{N} \in \mathcal{N}$ and $\mathcal{U} \subseteq \mathcal{U}_r = \{ T \in \mathcal{B}(\mathcal{H}) : TN \subseteq \widetilde{\mathcal{N}}, \forall N \in \mathcal{N} \}$. It follows from [4], Lemma 1.3, that $\mathcal{U}_r$ and $\mathcal{U}$ contain the same set of operators of rank one. Hence from [4], Lemma 1.2, each rank $n$ operator in $\mathcal{U}$ may be written as the sum of $n$ elements of $\mathcal{U}$ each having rank one, so $\Phi$ preserves rank.

Let $\mathcal{U}$ be a norm closed Alg$\mathcal{N}$-module, and let $\mathcal{O}(\mathcal{U})$ be the set of rank one operators in $\mathcal{U}$. It is easy to see from Proposition 3.1 that $\Phi(\mathcal{O}(\mathcal{U})) = \mathcal{O}(\mathcal{V})$. 

License or copyright restrictions may apply to redistribution; see http://www.ams.org/journal-terms-of-use
Lemma 3.2. Suppose that $U_i$ ($i = 1, 2, 3$) are norm closed $\text{Alg} N$-modules, and that $\Phi : U_1 \to U_2$, $\Psi : U_1 \to U_3$ are module isomorphisms. If for each rank one element $S$ of $U_1$, $\Phi(S) = \Psi(S)$, then $U_2 = U_3$ and $\Phi = \Psi$.

Proof. Suppose that there exists $T \in U_1$, such that $\Phi(T) \neq \Psi(T)$. Set $T' = \Phi(T) - \Psi(T) \neq 0$. From Lemma 2.1, there exists a rank one operator $S$ of $\text{Alg} N$ such that $ST' \neq 0$. Since $\dim \text{ran}(ST) \leq 1$, we have

$$ST' = S\Phi(T) - S\Psi(T) = \Phi(ST) - \Psi(ST) = 0,$$

which is a contradiction. Hence, for each $T \in U_1$, $\Phi(T) = \Psi(T)$ and $U_2 = U_3$. □

In the following, let $A$ be maximal abelian $*$-subalgebra of $\text{Alg} N$. It follows from [3], Lemma 2.8, that $A \supseteq \{ P(N) : N \in N \}$ and $A$ is a maximal abelian $*$-subalgebra of $B(H)$. For a norm closed $\text{Alg} N$-module $U$, we set $N_0 = \{ N \in N : N \neq 0, N_\sim \neq \emptyset \}$. Recall that $N_\sim = \bigvee \{ N' \in N : N' < N \}$ and $N^\perp = [U N'] = \tau(N')$.

Lemma 3.3. Suppose that $U, V$ are norm closed $\text{Alg} N$-modules. If $\Phi : U \to V$ is a module isomorphism, then for $N \in N_0$ and non-zero vectors $x_1, x_2 \in N, y \in N_\perp$, there exist non-zero vectors $u_i \in N, v \in N_\perp$ such that

$$\Phi(x_1 \otimes y) = u_i \otimes v, \quad i = 1, 2.$$

Proof. From [3], Lemma 1.1, $x_i \otimes y \in U_r$. It follows from [3], Lemma 1.3, that $U_r$ and $U$ contain the same set of operators of rank one, so $x_i \otimes y \in U$. Since $\Phi$ is a module isomorphism, it follows from Lemma 3.1 that there exist non-zero vectors $u_i, v_i$ ($i = 1, 2$) such that

$$\Phi(x_i \otimes y) = u_i \otimes v_i, \quad i = 1, 2.$$

Since

$$u_i \otimes v_i = \Phi(x_i \otimes y) = \Phi(P(N)(x_i \otimes y)P(N_\sim)) = P(N)\Phi(x_i \otimes y)P(N_\sim) = P(N)u_i \otimes P(N_\sim)v_i,$$

we may assume $u_i \in N, v_i \in N_\perp$.

It follows from [3], Lemma 2.11, that there exist $A_i \in A \subseteq \text{Alg} N$, $x \in H$ such that $A_i x = x_i$. Since

$$x_i = P(N)x_i = P(N)A_i x = A_i P(N)x,$$

we may assume $x \in N$ (if not, replace $x$ by $P(N)x$; since $P(N)$ and $A_i$ are members of $A$, and thus commute, the required conditions are still satisfied) and $\Phi(x \otimes y) = u_3 \otimes v_3$. Thus, we have that

$$\Phi(x_i \otimes y) = \Phi(A_i x \otimes y) = A_i \Phi(x \otimes y) = A_i u_3 \otimes v_3.$$

From (1) and (2), $v_1, v_2$ are linearly dependent. This completes the proof. □

Lemma 3.4. Suppose that $U, V$ are norm closed $\text{Alg} N$-modules. If $\Phi : U \to V$ is a module isomorphism, then for each $N \in N_0$, there exist injective linear maps $U_N : N \to N$ and $V_N : N^\perp \to N^\perp$ such that

$$\Phi(x \otimes y) = U_N x \otimes V_N y, \quad \forall x \in N, y \in N^\perp.$$

Proof. For each $0 \neq y \in N^\bot_w$, it follows from Lemma 3.3 that there exists an injective linear map $U_y : N \to N$ and a non-zero vector $v_y \in N^\bot_w$ such that

$$\Phi(x \otimes y) = U_y x \otimes v_y, \quad \forall x \in N.$$  

Thus, for $x \in N, y_i \in N^\bot_w$ ($i = 1, 2$), we have that

$$\Phi(x \otimes y_i) = U_{y_i} x \otimes v_{y_i}.$$  

From [9], Lemma 2.11, there exists $A_i \in A \subseteq \operatorname{Alg}N$ and $y_0 \in \mathcal{H}$ such that $A_i y_0 = y_i$. Since

$$y_i = P(N_w) v_i = \Phi(v_i) = \Phi(y_i) = \Phi(y_i) = \Phi(y_0) = \Phi(A_i y_0),$$

we may assume that $y_0 \in N^\bot_w$ and $\Phi(x \otimes y_0) = a \otimes b_0$, where $a \in N$ and $b_0 \in N^\bot_w$. Then we have that

$$\Phi(x \otimes y_i) = \Phi(x \otimes A_i y_0) = \Phi(x \otimes y_0) A_i^* = a \otimes A_i b_0, \quad i = 1, 2.$$  

By virtue of (4) and (5), we can show that there exists a non-zero complex number $\lambda$ (independent of $x$) such that

$$U_{y_i} x = \lambda U_{y_2} x, \quad \forall x \in N.$$  

Indeed, it follows from (4) and (5) that

$$U_{y_1} x \otimes v_{y_1} = a \otimes A_1 b_0$$  

and

$$U_{y_2} x \otimes v_{y_2} = a \otimes A_2 b_0.$$  

Thus there exist non-zero complex numbers $\lambda_i, \kappa_i$ ($i = 1, 2$) such that

$$U_{y_i} x = \lambda_1 a, \quad v_{y_1} = \kappa_1 A_1 b_0 \text{ and } \lambda_1 \overline{\kappa_1} = 1,$$

and

$$U_{y_2} x = \lambda_2 a, \quad v_{y_2} = \kappa_2 A_2 b_0 \text{ and } \lambda_2 \overline{\kappa_2} = 1.$$  

So

$$U_{y_1} x = \lambda_1 a = \frac{\lambda_1}{\lambda_2} \lambda_2 a = \frac{\lambda_1}{\lambda_2} U_{y_2} x = \frac{\lambda_2}{\kappa_1} \lambda_1 U_{y_2} x.$$  

Since $v_{y_1}$ and $A_1 b_0$ are independent of $x$, so $\kappa_i$ ($i = 1, 2$) are independent of $x$. Let $\lambda = \left(\frac{\lambda_2}{\lambda_1}\right)$. So there exists a non-zero complex number $\lambda$ (independent of $x$) such that $U_{y_1} = \lambda U_{y_2}$. Hence, if a suitable normalization is chosen, we may assume that $U_y$ is in fact independent of $y$, and write $U_N$ for $U_y$. Thus, (3) becomes

$$\Phi(x \otimes y) = U_N x \otimes v_y, \quad \forall x \in N, y \in N^\bot_w.$$  

For each $0 \neq y \in N^\bot_w$, we have that $0 \neq v_y \in N^\bot_w$ and $v_y$ depends linearly on $y$. Hence, the map $V_N : y \to v_y$ is an injective linear map from $N^\bot_w$ into itself. So

$$\Phi(x \otimes y) = U_N x \otimes V_N y, \quad \forall x \in N, y \in N^\bot_w.$$  

□

**Proposition 3.1.** Suppose that $U, V$ are norm closed $\operatorname{Alg}N$-modules, and that $\Phi : U \to V$ is a module isomorphism. Then there exists a non-zero complex number $\lambda$ such that $\Phi(S) = \lambda S, \forall S \in \mathcal{O}(U)$.  

Proof. For each $N \in \mathcal{N}_0$, it follows from Lemma 3.4 that there exist injective linear maps $U_N : N \to N$ and $V_N : N_+ \to N_+$ such that
\[
\Phi(x \otimes y) = U_N x \otimes V_N y, \quad \forall x \in N, y \in N_+.
\]
Suppose that $N_1, N_2 \in \mathcal{N}_0$ and $N_1 \subset N_2$, which follows from the definition of $N_\prec$ that $N_1 \prec \leq N_2 \prec$. Thus, for each $x \in N_1$ and $y \in N_2$, we have that
\[
\Phi(x \otimes y) = U_{N_1} x \otimes V_{N_1} y = U_N x \otimes V_N y.
\]
Hence there exist non-zero numbers $\xi, \eta$ such that $\xi \eta = 1$ and
\[
U_{N_1} = \xi U_N |_{N_1}, \quad V_{N_1} |_{N_2} = \eta V_N.
\]
We now choose and fix a subspace $N_0 \in \mathcal{N}_0$. For each $N \in \mathcal{N}_0$, the maps $U_N$ and $V_N$ may be normalized in such a way that they are equal to $U_{N_0}$ and $V_{N_0}$ on common domain respectively. Thus, we can define the linear maps
\[
U : \bigcup \{ N : N \in \mathcal{N}_0 \} \rightarrow \bigcup \{ N : N \in \mathcal{N}_0 \}, \quad U |_{N} = U_N, \quad \forall N \in \mathcal{N}_0,
\]
and
\[
V : \bigcup \{ N_+ : N \in \mathcal{N}_0 \} \rightarrow \bigcup \{ N_+ : N \in \mathcal{N}_0 \}, \quad V |_{N_+} = V_N, \quad \forall N \in \mathcal{N}_0.
\]
For each $x \otimes y \in \mathcal{U}$, it follows from [4], Lemma 1.1 and Lemma 1.3, that there exists $N \in \mathcal{N}_0$ such that $x \in N$ and $y \in N_+$. Hence
\[
(6) \quad \Phi(x \otimes y) = U_N x \otimes V_N y = U x \otimes V y.
\]
In the following, we will prove that the linear maps $U, V$ are trivial. For each $A \in \mathcal{A} \subseteq \text{Alg} \mathcal{N}$, $N \in \mathcal{N}_0$, $x \in N$ and $y \in N_+$, we have that $\Phi(A x \otimes y) = A \Phi(x \otimes y)$ and $Ax \in N$. Hence
\[
U_N Ax \otimes V_N y = AU_N x \otimes V_N y, \quad \forall x \in N, y \in N_+.
\]
and
\[
U_N Ax = AU_N x, \quad \forall x \in N.
\]
So the linear map $U_N : N \to N$ commutes with $P(N) A P(N)$, the algebra being interpreted as acting on the space $N$. Since $P(N) A P(N)$ is a maximal abelian $*$-algebra in $\mathcal{B}(N)$, it follows from [4], Lemma 2.12, that $U_N$ is continuous. Now for each $T \in \text{Alg} \mathcal{N}$, the same argument shows that
\[
U_N T x = T U_N x, \quad \forall x \in N.
\]
This shows that the bounded operator $U_N$ in $\mathcal{B}(N)$ commutes with the nest algebra $P(N) \text{Alg} \mathcal{N} P(N) = \text{Alg} (N \cap N)$. Since the commutant of a nest algebra is trivial (see [4], Lemma 3.6), there exists a non-zero number $\lambda_N \in \mathbb{C}$ such that $U_N = \lambda_N P(N)$. Similarly, there exists a non-zero number $\mu_N \in \mathbb{C}$ such that $V_N = \mu_N P(N_+)$. For each $N \in \mathcal{N}_0$, since $U_N$ and $V_N$ are equal to $U_{N_0}$ and $V_{N_0}$ on common domain respectively, we obtain that $\lambda_N = \lambda_{N_0}$ and $\mu_N = \mu_{N_0}$. Therefore,
\[
U x = \lambda_{N_0} x, \quad \forall x \in \bigcup \{ N : N \in \mathcal{N}_0 \}
\]
and
\[
V y = \mu_{N_0} y, \quad \forall y \in \bigcup \{ N_+ : N \in \mathcal{N}_0 \}.
\]
Let $\lambda = \lambda_{N_0} \mu_{N_0}$. For each $x \otimes y \in \mathcal{U}$, it follows from the equation (6) that
\[
\Phi(x \otimes y) = \lambda_{N_0} \mu_{N_0} x \otimes y = \lambda x \otimes y.
\]
□
Now we will give the main result of this paper.

**Theorem 3.1.** Suppose that $\mathcal{U}$ and $\mathcal{V}$ are norm closed $\text{Alg}\mathcal{N}$-modules, and that $\Phi : \mathcal{U} \to \mathcal{V}$ is a module isomorphism. Then $\mathcal{U} = \mathcal{V}$ and there exists a number $\lambda$ such that $\Phi(T) = \lambda T, \forall T \in \mathcal{U}$.

**Proof.** It follows from Proposition 3.1 that there exists a non-zero number $\lambda$ such that

$$
\Phi(S) = \lambda S, \quad \forall S \in \mathcal{O}(\mathcal{U}).
$$

For each $T \in \mathcal{U}$, we consider two cases separately.

**Case 1.** $\mathcal{H} \neq \mathcal{H}$. For each non-zero vector $x \in \mathcal{H}$ and $y \in \mathcal{H} \ominus \mathcal{H}$, the rank one operator $x \otimes y \in \text{Alg}\mathcal{N}$. Hence,

$$
\Phi(T)x \otimes y = \Phi(Tx \otimes y) = \lambda Tx \otimes y.
$$

Therefore, we have

$$
\Phi(T)x = \lambda Tx, \quad \forall x \in \mathcal{H},
$$

$$
\Phi(T) = \lambda T.
$$

**Case 2.** $\mathcal{H} = \mathcal{H}$. Choose an increasing sequence $\{N_k\} \subseteq \mathcal{N}$, $N_k \neq \mathcal{H}$ and $P(N_k) \to \mathcal{I}$. For each $x \in \mathcal{H}$, $0 \neq y_k \in N_k$, we have that $P(N_k)x \otimes y_k \in \text{Alg}\mathcal{N}$. So

$$
\Phi(T)P(N_k)x \otimes y_k = \Phi(TP(N_k)x \otimes y_k) = \lambda TP(N_k)x \otimes y_k,
$$

$$
\Phi(T)P(N_k)x = \lambda TP(N_k)x, \quad \forall x \in \mathcal{H}.
$$

By taking a limit, we obtain that

$$
\Phi(T)x = \lambda Tx, \quad \forall x \in \mathcal{H},
$$

$$
\Phi(T) = \lambda T.
$$

From Case 1 and Case 2, it follows that $\Phi(T) = \lambda T, \forall T \in \mathcal{U}$. Thus we have $\mathcal{U} = \mathcal{V}$, and this completes the proof. \qed

Theorem 3.1 shows that different norm closed $\text{Alg}\mathcal{N}$-modules cannot be module isomorphic.
