LINEARIZED STABILITY OF TRAVELING CELL SOLUTIONS ARISING FROM A MOVING BOUNDARY PROBLEM

Y. S. CHOI AND ROGER LUI

(Communicated by M. Gregory Forest)

Abstract. In 2003, Mogilner and Verzi proposed a one-dimensional model on the crawling movement of a nematode sperm cell. Under certain conditions, the model can be reduced to a moving boundary problem for a single equation involving the length density of the bundled filaments inside the cell. It follows from the results of Choi, Lee and Lui (2004) that this simpler model possesses traveling cell solutions. In this paper, we show that the spectrum of the linear operator, obtained from linearizing the evolution equation about the traveling cell solution, consists only of eigenvalues and there exists \( \mu > 0 \) such that if \( \lambda \) is a real eigenvalue, then \( \lambda \leq -\mu \). We also provide strong numerical evidence that this operator has no complex eigenvalue.

1. Introduction

In this paper we study the eigenvalue problem

\[
\begin{aligned}
\mathcal{L}\phi - p(x)c + a(x)\phi'(0) + b(x)\phi'(1) &= \lambda \phi , \\
-\alpha c + \beta (\phi'(0) - \phi'(1)) &= \lambda c ,
\end{aligned}
\]

with \( \phi(0) = \phi(1) = 0 \) for some particular differential operator \( \mathcal{L} \), known functions \( a, b, p \), and known constants \( \alpha \) and \( \beta \). The precise form of the equations is given in (2.7). Here, \((\phi, c)\) is an “eigenfunction” consisting of a function \( \phi(x) \) and a constant \( c \) and \( \lambda \) is the eigenvalue. The above system arises naturally as one performs linearized stability analysis on the traveling cell solution of a moving boundary problem modeling cell motility. The function \( \phi \) and the constant \( c \) correspond to perturbations of the traveling cell solution and the cell size, respectively. The cell motility model was developed by Mogilner and Verzi in [3] and the traveling cell solution of the model was shown to exist by Choi, Lee, and Lui in [1]. We refer readers to these papers for details of the model and an existence proof of the traveling cell solutions.
Under some simplifying conditions, it can be shown (see [2]) that the Mogilner-Verzi model reduces to the following moving boundary problem:

\[
\begin{align*}
\frac{b_t}{\xi_0} &= \rho K \left( \frac{bb_x}{\xi_0} \right)_x - \gamma_b b, \\
b(r, t) &= b_0, \quad b(f, t) = b_0, \\
r' &= V_d - \rho K b_x(0, t)/\xi_0, \\
f' &= L/\ell - \rho K b_x(\ell, t)/\xi_0.
\end{align*}
\]

This system of equations is assumed to hold in the domain \( \{(x, t) : r(t) < x < f(t), t > 0\} \), where \( r(t), f(t) \) denote the rear and front end of the cell, respectively. Also, \( b \) denotes the length density of the bundled filaments inside the cell, \( \rho, K, \xi_0, \gamma_b, b_0, V_d \) and \( L \) are positive constants each with their own biological meaning, and \( \ell(t) = f(t) - r(t) \) is the length of the cell. Global existence of this moving boundary problem has been proved by Choi, Groulx and Lui in [2].

In [1], Choi, Lee, and Lui proved the existence of traveling cell solutions for the Mogilner-Verzi model, which implies the existence of traveling cell solutions for (1.2). Traveling cell solutions are special solutions of the form \( b(x, t) = \bar{b}(x - kt) \). Biologically, this means that the cell maintains a constant shape and moves with a constant velocity \( k \). If the traveling cell has constant length \( \bar{\ell} \) and moves with velocity \( \bar{k} \), then \( r(t) = \bar{r}t \) and \( f(t) = \bar{f} + \bar{k}t \). Substituting this form of solution into (1.2) and using \( y = x - \bar{k}t \), the traveling cell system is

\[
\begin{align*}
0 &= \rho K \left[ \bar{b} \bar{b}'/\xi_0 \right]' + \bar{\ell} \bar{b}' - \gamma_b \bar{b}, \\
\bar{b}(0) &= b_0, \quad \bar{b}(\bar{\ell}) = b_0, \\
\bar{k} &= V_d - \rho K \bar{b}_x(0)/\xi_0, \\
\bar{k} &= L/\ell - \rho K \bar{b}_x(\ell)/\xi_0,
\end{align*}
\]

where \( ' = d/dy \). For simplicity, we also assume that \( L = \rho K/\xi_0 = 1 \) in (1.2) and (1.3) so that we do not have to carry these constants around in our future calculations.

## 2. The linearized system

To study the stability of the traveling cell solution, we linearize (1.2) about the traveling cell solution. To this end, we straighten out the moving boundaries by
letting \( \varphi = (x - r(t))/(f(t) - r(t)) \) and then write \( x \) for \( \varphi \). System \((1.2)\) becomes

\[
\begin{cases}
  b_t = \frac{1}{\ell^2} \left( \frac{b^2}{2} \right)_{xx} + \left( \frac{r' + x \ell'}{\ell} \right) b_x - \gamma b b, \\
b(0, t) = b_0, \quad b(1, t) = b_0, \\
r' = V_d - \frac{b_x(0, t)}{\ell}, \\
f' = \frac{1}{\ell} - \frac{b_x(1, t)}{\ell}.
\end{cases}
\]

Let \( \tilde{b}(x) = \tilde{b}(x \ell) \). From \((1.3)\), we obtain a system of equations for \( \tilde{b} \), which we shall not display. Let \( u = b - \tilde{b}, \ \zeta_1 = \ell - \tilde{b}, \ \zeta_2 = r - \tilde{b} t \). After some tedious calculations, the linearized system is

\[
\begin{cases}
  u_t = \mathcal{L}u + \left[ -\frac{2}{\ell^3} \left( \frac{\tilde{b}^2}{2} \right)_{xx} - \frac{\tilde{b}^2}{\ell^2} \tilde{b}_x \right] \zeta_1 + \frac{\tilde{b}_x}{\ell} [x \zeta_{1t} + \zeta_{2t}], \\
  \zeta_{1t} = -\frac{V_d}{\ell} \zeta_1 - \left( \frac{u_x(1, t) - u_x(0, t)}{\ell} \right), \\
  \zeta_{2t} = -\frac{u_x(0, t)}{\ell} + \frac{\tilde{b}_x(0)}{\ell^2} \zeta_1,
\end{cases}
\]

where

\[
\mathcal{L}u = \frac{1}{\ell^2} \left( \frac{\tilde{b} u}{2} \right)_{xx} + \frac{\tilde{b}}{\ell} u_x - \gamma b u,
\]

and \( u(0, t) = u(1, t) = 0 \) for \( t \geq 0 \). Substituting \( \zeta_{1t}, \zeta_{2t} \) from \((2.2a), (2.2c)\) into \((2.2b)\) and employing the equation for \( \tilde{b} \) derived from \((1.3b)\), the linearized system may be written as

\[
\begin{cases}
  u_t = \mathcal{L}u - p(x) \zeta_1 - E_1 u, \\
  \zeta_{1t} = -\frac{V_d}{\ell} \zeta_1 + E_2 u,
\end{cases}
\]

where \( u(0, t) = u(1, t) = 0, \ p(x) = 2 \gamma_b \tilde{b}/\ell - (1 - x) V_d \tilde{b}_x/\ell^2 \),

\[
E_1 u = \frac{\tilde{b}_x}{\ell^2} [x u_x(1, t) + (1 - x)u_x(0, t)]
\]

and

\[
E_2 u = \frac{u_x(0, t) - u_x(1, t)}{\ell}.
\]

Let \( u(x, t) = \phi(x)e^{\lambda t} \) and \( \zeta_1(t) = ce^{\lambda t} \). Then \((2.4)\) becomes

\[
\begin{cases}
  \mathcal{L}\phi - p(x) c e - E_1 \phi = \lambda \phi, \\
  -\frac{V_d}{\ell} e + E_2 \phi = \lambda c,
\end{cases}
\]

where \( \phi(0) = \phi(1) = 0 \). The main results of this paper are the following propositions.
Proposition 2.1. The spectrum of the operator on the left of (2.7) consists only of eigenvalues.

Proposition 2.2. Let $\lambda$ be an eigenvalue of (2.7). (a) Suppose $c = 0$. Then $\Re e(\lambda) \leq -\gamma_b$. (b) Suppose $c \neq 0$ and $\lambda$ is real. Then $\lambda \leq \max\{-\gamma_b, -V_d/\ell\}$.

Remark. We conjecture that system (2.7) consists only of real eigenvalues and in the last section of this paper, we provide strong numerical evidence to support our conjecture. From Proposition 2.2 all real eigenvalues correspond to stable modes and therefore, if our conjecture is true, the traveling wave solution is linearly stable. However, because (2.7) is nonlocal, meaning that $E_1, E_2$ involve $\phi$ at the boundary points, it is not clear if this implies local stability of the traveling cell solution.

Proof of Proposition 2.1. Let the linear operator on the left-hand side of (2.7) be denoted by $\mathcal{A}$. It is clear that $\mathcal{A}$ has only a discrete spectrum if and only if $\mathcal{A} - aI$ does for a large positive constant $a$. We now show that the inverse operator $(\mathcal{A} - aI)^{-1}$ is defined and compact.

Consider the equation $\mathcal{A}u = au = f$, where $f = (f_1, f_2) \in C[0,1] \times \mathbb{R}$ is given and we need to solve for $u = (\phi, c)$. Solving for $c$ from (2.7) and substituting the result into (2.7), we obtain

$$L\phi - a\phi - p(x) \frac{\ell}{V_d + a\ell} (E_2\phi - f_2) - E_1\phi = f_1.$$  

Simplifying, this equation can be written in the form

$$(2.8) \quad \phi'' - a\phi = \beta \{p_1(x, a)c' \phi'(0) + p_2(x, a)c' \phi(1) + p_3(x)c' \phi + p_4(x)c' \phi' + f_3(x, a)\}$$

with boundary conditions $\phi(0) = \phi(1) = 0$. Here, $\beta = 1, p_i(\cdot, a), i = 1, \ldots, 4$, and $f_3(\cdot, a)$ are known functions belonging to $C[0,1]$ and their $C[0,1]$ bounds are independent of $a$ for $a \geq 0$.

We now establish a priori bounds on the solution $\phi$ for $0 \leq \beta \leq 1$. Letting $\beta g$ denote the right side of (2.8), we have $\phi(x) = \beta \int_0^1 G(x, y, a) g(y) dy$, where the Green’s function $G(x, y, a)$ can be explicitly calculated. It follows that $\phi'(x) = \beta \int_0^1 G_y(x, y, a) g(y) dy$ even though $G_y$ has a discontinuity when $x = y$. Using the explicit form of $G$, we have

$$(2.9) \quad |\phi'(x)| \leq \beta ||g||_{C[0,1]} \int_0^1 |G_y(x, y, a)| dy \leq \frac{M_1 \beta}{\sqrt{a}} ||g||_{C[0,1]},$$

where $M > 0$ is independent of $a \geq 0$ and $\beta$. From the definition of $g$, we have

$$||\phi'||_{C[0,1]} \leq \frac{M_1 \beta}{\sqrt{a}} (||\phi||_{C[0,1]} + ||f||_{C[0,1]} + ||f'||_{C[0,1]}) \leq \frac{M_2 \beta}{\sqrt{a}} (||\phi||_{C[0,1]} + ||f||_{C[0,1]})$$

since $\phi(0) = 0$. Let $a = 4M_2^2$. Since $0 \leq \beta \leq 1$, we obtain the a priori estimate

$$(2.10) \quad ||\phi'||_{C[0,1]} \leq \beta ||f||_{C[0,1]}.$$  

This immediately leads to a bound on $||\phi||_{C[0,1]}$. Using (2.8), we obtain an a priori bound on the $C^2[0,1]$ norm of $\phi$. This bound is independent of $\beta$. Since (2.8) has a solution when $\beta = 0$ with a non-zero degree, using a homotopy argument in standard degree theory, we obtain the existence of a solution to (2.7). The estimate (2.10) implies uniqueness of such a solution. Hence, the inverse operator $(\mathcal{A} - aI)^{-1} : C[0,1] \times \mathbb{R} \to C[0,1] \times \mathbb{R}$ is well defined and the bound (2.10) implies that it is a compact operator. The proof of the proposition is complete. \qed
We close this section by deriving some properties of the coefficients in (2.7).

**Lemma 2.1.** (i) $\tilde{b}$ is strictly convex on $[0, 1]$ and there exists $x^* \in (0, 1)$ such that $\tilde{b}$ is strictly decreasing on $(0, x^*)$ and strictly increasing on $(x^*, 1)$.

(ii) $p$ defined above satisfies $p(x) \geq 0$.

**Proof.** (i) Let $v = \tilde{b}_x$. Then $v$ satisfies the equation $\tilde{b}v_{xx} + 3vv_x - V_0 V_d - \gamma_0 \tilde{b}^2 v = 0$. From Lemma 3.1 of [11], $V_d < \bar{V} < V_0(\bar{V})$ so that (13.3,d) imply that $v(0) < 0$ and $v(1) > 0$. From the differential equation above, $v$ cannot have a positive maximum or a negative minimum, hence $v$ is increasing on $[0, 1]$ and $\tilde{b}$ is convex. From Hopf’s boundary point lemma, it is easy to see that $\tilde{v}_x > 0$ and $\tilde{b}$ is strictly convex on $[0, 1]$. The rest of (i) is obvious.

(ii) The fact that $p \geq 0$ is clear from its definition on the interval $[0, x^*]$. On the interval $[x^*, 1]$, we have

$$p(x) = \frac{2}{\ell} \left( \frac{\tilde{b}^2}{2} \right)_{xx} + 2\bar{V}_d \tilde{b}_x - (1 - x)V_d \tilde{b}_x$$

$$= \frac{2}{\ell} \tilde{b} \tilde{b}_{xx} + \frac{2}{\ell} \tilde{b}_x^2 + [2\bar{V} - (1 - x)V_d] \tilde{b}_x \geq 0$$

since $\bar{V} > V_d$ and $\tilde{b}$ is convex. The proof of the lemma is complete. □

### 3. Proof of Proposition 2.2

We separate the proof into two cases, when $c = 0$ and when $c \neq 0$.

**Lemma 3.1.** Suppose $c = 0$ and $\lambda = \lambda_1 + i\lambda_2$ is an eigenvalue of (2.7). Then $\gamma_0 + \lambda_1 \leq 0$.

**Proof.** From (2.7b) and (2.6), we have $\phi_x(0) = \phi_x(1)$. From the definition of $E_1$, (2.7) may be reduced to a single equation

$$\frac{1}{\ell}(\tilde{b} \phi)_{xx} + \frac{\bar{V}}{\ell} \phi_x - \gamma_0 \phi - \frac{\tilde{b}_x}{\ell} \phi_x(0) = \lambda \phi$$

with $\phi(0) = \phi(1) = 0$. From (1.3), $\tilde{b}$ is analytic and hence $\phi$ is also analytic and has at most a finite number of zeros on $[0, 1]$.

**Case 1:** $\lambda = 0$. Without loss of generality, we may assume that $\phi$ is real. Integrating (5.1), we have $\int_0^1 \phi = 0$ and hence $\phi$ must change sign in $[0, 1]$. Let $\beta_0 < 1$ be the last interior zero of $\phi$ on $[0, 1]$. Without loss of generality, we may assume that $\phi < 0$ on $(\beta_0, 1)$. Integrating (5.1) over $[\beta_0, 1]$, we have

$$\int_{\beta_0}^1 \frac{1}{\ell} \left[ b_0 \phi_x(1) - \tilde{b}(\beta_0) \phi_x(\beta_0) \right] - \gamma_0 \int_{\beta_0}^1 \phi = \frac{\phi_x(0)}{\ell^2} \left[ b_0 - \tilde{b}(\beta_0) \right].$$

Rearranging, we have

$$\gamma_0 \int_{\beta_0}^1 \phi = \frac{\tilde{b}(\beta_0)}{\ell} \left[ \phi_x(0) - \phi_x(\beta_0) \right].$$

The right side is non-negative because $\phi_x(0) = \phi_x(1) \geq 0$ and $\phi_x(\beta_0) \leq 0$ while the left side is negative since $\phi < 0$ on $(\beta_0, 1)$. This contradiction implies that $\lambda$ is not an eigenvalue if $c = 0$. 

License or copyright restrictions may apply to redistribution; see http://www.ams.org/journal-terms-of-use
Case 2: \( \lambda \neq 0 \). Assume \( \gamma_b + \lambda_1 > 0 \) and let \( \psi(x) = \int_0^x \phi(t) \, dt \). Integrating (3.1), we have

\[
\frac{1}{\ell} \left( \ddot{b} \psi_x \right)_x + \frac{\ell}{\ell} \psi_x - \gamma_b \psi - \frac{\dot{b}}{\ell^2} \psi_x(0) = \lambda \psi
\]

with \( \psi(0) = \psi(1) = \psi_x(0) = \psi_x(1) = 0 \). Without loss of generality we assume that \( \psi_{xx}(0) = 1 \) and \( \lambda_2 \geq 0 \). Equation (3.2) has a particular solution \( \psi_p = -\dot{b}/\ell^2 \). Let \( \psi = \psi_p + \psi_c \), where \( \psi_c \) satisfies

\[
\frac{1}{\ell} \left( \ddot{b} \psi_c \right)' + \frac{\ell}{\ell} \psi_c - \gamma_b \psi_c = \lambda \psi
\]

and the boundary conditions \( \psi_c(0) = -\psi_p(0), \psi'_c(0) = -\psi'_p(0), \psi_c(1) = -\psi_p(1), \psi'_c(1) = -\psi'_p(1) \). Multiplying (3.3) by \( w(x) = \exp(\int_0^x \ell \dot{b}/\ell) \), we can convert the equation into the self-adjoint form

\[
\frac{1}{\ell} (w \ddot{b} \psi_c)' - \gamma_b w \psi_c = \lambda w \psi_c.
\]

Multiplying (3.4) by \( \ddot{b} \), integrating and then taking the imaginary parts, we obtain

\[
\lambda_2 \int_0^1 w |\psi_c|^2 = \frac{1}{\ell^2} \left\{ w \ddot{b} \Im(\ddot{b} \psi_c') \right\} \bigg|_0^1 = \frac{1}{\ell^2} \left\{ w \ddot{b} \Im(\ddot{b} \psi_p') \right\} \bigg|_0^1 = 0.
\]

Thus, either \( \psi_c \equiv 0 \) or \( \lambda_2 = 0 \). In the former case, we have \( \psi = \psi_p \), which does not satisfy \( \psi(0) = 0 \). Therefore, \( \lambda_2 = 0 \) and both \( \lambda = \lambda_1 \) and \( \psi \) are real. From (3.2), we have

\[
\frac{1}{\ell} \left( \ddot{b} \psi_x \right)_x + \frac{\ell}{\ell} \psi_x - (\gamma_b + \lambda_1) \psi = \frac{\dot{b}}{\ell^2} > 0, \quad \psi(0) = 0, \quad \psi(1) = 0.
\]

Since \( \gamma_b + \lambda_1 > 0 \), the maximum principle implies that \( \psi \leq 0 \) on \( [0, 1] \). From Hopf’s boundary point lemma, either \( \psi'(0) < 0 \) and \( \psi'(1) > 0 \) or \( \psi \equiv 0 \). Both cases are impossible because we already know that \( \psi'(0) = \psi'_p(1) = 0 \) and \( \psi \equiv 0 \) won’t satisfy (3.6). Thus, \( \gamma_b + \lambda_1 \leq 0 \) and the proof of the lemma is complete. \( \square \)

Lemma 3.2. If \( c \neq 0 \) and \( \lambda \) is real, then \( \lambda \ell + V_d > 0 \) and \( \lambda + \gamma_b > 0 \) cannot both hold.

Proof. We assume that \( \lambda \ell + V_d > 0 \) and \( \lambda + \gamma_b > 0 \) and arrive at a contradiction. In what follows, we shall call \( \alpha \) an interior zero of \( \phi \) if \( 0 < \alpha < 1, \phi(\alpha) = 0, \phi \) changes sign across \( \alpha \).

Solving for \( c \) from (2.4b) and substituting the result into (2.4a), we have

\[
\frac{1}{\ell^2} \left( \ddot{b} \phi \right) + \frac{\ell}{\ell} \phi_x - \gamma_b \phi + \left( -\frac{2 - \gamma_b - \lambda \ell}{\lambda \ell + V_d} \right) E_2 \phi = -\frac{V_d \phi_x(1)}{\lambda \ell + V_d} + \frac{\lambda \ell + V_d}{\lambda \ell^2 + V_d} E_2 \phi = -\omega(\lambda + \gamma_b) \phi.
\]

Thus, \( \ddot{b}(0) = \ddot{b}(1) = b_0 \) and \( \int_0^1 \ddot{b} \phi_x = b_0 - \int_0^1 \ddot{b} \), we integrate (3.7) and obtain

\[
E_2 \phi = \frac{-\omega(\lambda + \gamma_b)(\lambda \ell^2 + V_d)}{b_0 V_d + (\lambda + 2 \gamma_b) \ell} \int_0^1 \phi = -\omega(\lambda + \gamma_b) \int_0^1 \phi.
\]
where

\begin{equation}
(3.9) \quad \omega = \frac{(\lambda \ell^2 + V_\delta \ell^2)}{b_0 V_d + (\lambda + 2 \gamma b) \ell \int_0^1 b} > 0
\end{equation}

because of our hypotheses. Substituting (3.8) into (3.7) and simplifying, we obtain

\begin{equation}
(3.10) \quad \frac{1}{\ell^2} (\tilde{b} \phi_{xx} + \frac{\kappa}{\ell} \phi_x - \gamma \phi + \frac{2 \gamma \beta - \lambda x b_x (\lambda + 2 \gamma b)}{b_0 V_d + (\lambda + 2 \gamma b) \ell \int_0^1 b} \phi) + \frac{V_\delta b_x \phi_x (1)}{\lambda \ell^2 + V_\delta \ell} = \lambda \phi.
\end{equation}

Equation (3.10) is in the form of \((\tilde{b} \phi / \ell^2)_{xx} + \frac{\kappa}{\ell} \phi_x - (\gamma + \lambda) \phi + c_1 \tilde{b} + c_2 \tilde{b}_x + c_3 x \tilde{b}_x = 0\). Since \(\tilde{b}\) is analytic, so is \(\phi\), which therefore has only finite number of zeros on the interval \([0, 1]\).

Let \(0 \leq \alpha < \beta \leq 1\) be two zeros of \(\phi\). Integrating (3.10) over \([\alpha, \beta]\), we have

\begin{equation}
(3.11) \quad \frac{1}{\ell} \left[ \frac{\tilde{b}(\beta) \phi_x (\beta) - \tilde{b}(\alpha) \phi_x (\alpha)}{b_0 V_d + (\lambda + 2 \gamma b) \ell \int_0^1 b} - (\gamma + \lambda) \int_\alpha^\beta \phi + \eta_{\alpha, \beta} (\gamma + \lambda) \right] \int_0^1 \phi

\begin{equation}
(3.12) \quad \eta_{\alpha, \beta} = \frac{(\lambda + 2 \gamma) \ell \int_0^2 \tilde{b} - \lambda \ell (\tilde{b}(\beta) - \alpha \tilde{b}(\alpha))}{b_0 V_d + (\lambda + 2 \gamma) \ell \int_0^1 b}.
\end{equation}

Let \(\alpha_0\) and \(\beta_0\) be the first and last interior zeros of \(\phi\) on \([0, 1]\), respectively. We may assume that \(\phi < 0\) on \((\beta_0, 1)\) so that \(\phi_x (1) \geq 0\) and \(\phi_x (\beta_0) \leq 0\). Letting \(\alpha = \beta_0\) and \(\beta = 1\) in (3.11), we have

\begin{equation}
(3.13) \quad \frac{\phi_x (1) [b_0 \lambda \ell + V_\delta \tilde{b}(\beta_0)]}{(\lambda \ell^2 + V_\delta \ell^2)} - \frac{\tilde{b}(\beta_0) \phi_x (\beta_0)}{\ell^2} - \frac{\lambda \phi_x (0) [b_0 - \tilde{b}(\beta_0)]}{\lambda \ell^2 + V_\delta \ell^2}

\begin{equation}
(3.14) \quad -(\gamma + \lambda) \int_{\beta_0}^1 \phi + \eta_1 (\gamma + \lambda) \int_0^1 \phi = 0.
\end{equation}

Letting \(\alpha = 0\) and \(\beta = \alpha_0\) in (3.11), we have

\begin{equation}
(3.15) \quad \frac{-\phi_x (0) [b_0 V_d + \lambda \tilde{b}(\alpha_0) \ell]}{(\lambda \ell^2 + V_\delta \ell^2)} + \frac{\tilde{b}(\alpha_0) \phi_x (\alpha_0)}{\ell^2} - \frac{V_\delta \phi_x (1) [\tilde{b}(\alpha_0) - b_0]}{\lambda \ell^2 + V_\delta \ell^2}

\begin{equation}
(3.16) \quad -(\gamma + \lambda) \int_0^{\alpha_0} \phi + \eta_0 (\gamma + \lambda) \int_0^1 \phi = 0.
\end{equation}

In the above equations \(\eta_0 = \eta_{0_000}\) and \(\eta_1 = \eta_{111}\). We now divide the proof into two cases:

Case 1: \(\phi\) has an even number of interior zeros. We may assume that \(\phi < 0\) on \((0, \alpha_0)\).

Subcase (a): \(\alpha_0 < x^*\). We first claim that \(b_0 V_d + \lambda \tilde{b}(\alpha_0) \ell \geq 0\). This is clear if \(\lambda \geq 0\). If \(\lambda < 0\), then \(b_0 V_d + \lambda \tilde{b}(\alpha_0) \ell \geq b_0 (V_d + \lambda) \geq 0\) from our hypothesis. Since
φ_x(0) ≤ 0, φ_x(α_0) ≥ 0 and φ_x(1) ≥ 0, (3.14) implies that \( η_0 \int_0^1 φ < 0 \). We claim that

\[
η_0 = \frac{(λ + 2γ_b) \int_0^{α_0} \tilde{b} - \lambda \tilde{t} α_0 \tilde{b}(α_0)}{b_0 V_d + (λ + 2γ_b) \int_0^1 \tilde{b}} > 0.
\]

This is clear if \( λ ≤ 0 \). If \( λ > 0 \), then since \( \tilde{b} \) is decreasing on \((0, x^*)\), \( \int_0^{α_0} \tilde{b} - α_0 \tilde{b}(α_0) > 0 \) and hence \( η_0 > 0 \). From above, \( \int_0^1 φ < 0 \). On the other hand, since \( φ_x(0) ≤ 0 \) and \( φ_x(1) ≥ 0 \), (2.6) implies that \( E_2 φ ≤ 0 \). From (3.8), \( \int_0^1 φ ≥ 0 \), which is a contradiction.

Subcase (b): \( α_0 > x^* \). Letting \( α = α_0 \) and \( β = β_0 \) in (3.11) and rearranging, we have

\[
\frac{1}{ℓ} \left[ \tilde{b}(β_0)φ_x(β_0) - \tilde{b}(α_0)φ_x(α_0) \right] - \frac{V_d φ_x(1)[\tilde{b}(β_0) - \tilde{b}(α_0)]}{λ^2 + V_d ℓ^2} = 0,
\]

(3.15)

\[-(γ_b + λ) \int_0^{β_0} φ + λ(γ_b + λ) \int_0^1 φ - \frac{λφ_x(0)[\tilde{b}(β_0) - \tilde{b}(α_0)]}{λ^2 + V_d ℓ^2} = 0,
\]

where \( η = η_{α_0 β_0} \). First we consider the 2nd and the 5th terms on the left-hand side of (3.15). From (3.8), \( φ_x(0) = φ_x(1) - (λ + γ_b)ω \int_0^1 φ \), we have

\[-\frac{V_d φ_x(1)[\tilde{b}(β_0) - \tilde{b}(α_0)]}{λ^2 + V_d ℓ^2} - \frac{λφ_x(0)[\tilde{b}(β_0) - \tilde{b}(α_0)]}{λ^2 + V_d ℓ^2} = 0.
\]

(3.16)

From our hypotheses, the first term on the right of the above equation is non-positive. Since \( φ_x(β_0) ≤ 0 \) and \( φ_x(α_0) ≥ 0 \), the first term on the left of (3.15) is also non-positive. Finally, since \( φ < 0 \) on \((0, α_0)\) and \((β_0, 1)\), we have \( \int_0^{β_0} φ > \int_0^1 φ \). These facts and (3.15) together imply that

\[
\left( -1 + \frac{λω[\tilde{b}(β_0) - \tilde{b}(α_0)]}{λ^2 + V_d} \right) \int_0^1 φ > 0.
\]

(3.17)

Since \( φ_x(0) ≤ 0 \) and \( φ_x(1) ≥ 0 \), (2.6) implies that \( E_2 φ ≤ 0 \). From (3.8), \( \int_0^1 φ ≥ 0 \) so that (3.17) is still valid without the integral term. Substituting the definitions of \( ω \) and \( η \) (see (3.12), (3.14)) into (3.17) and simplifying, we have

\[
-b_0 V_d - (λ + 2γ_b) \int_0^1 \tilde{b} + (λ + 2γ_b) \int_0^{β_0} \tilde{b} - λ\tilde{t} β_0 \tilde{b}(β_0) - α_0 \tilde{b}(α_0))
\]

\[+ λ\tilde{t}[\tilde{b}(β_0) - \tilde{b}(α_0)] > 0,
\]

which can be rewritten as

\[-b_0 V_d - 2γ_b \int_0^1 \tilde{b} - \int_0^{β_0} \tilde{b} - λ\tilde{t} \left[ \int_0^1 \tilde{b} - \int_0^{β_0} (1 - x) \tilde{b}_x \right] > 0.
\]

If \( λ ≤ 0 \), then since \( b_0 V_d + λ\tilde{t} \int_0^1 \tilde{b} ≥ b_0 (V_d + λ\tilde{t}) > 0 \) and \( \tilde{b}_x ≥ 0 \) on \([x^*, 1]\), the above inequality produces a contradiction. If \( λ > 0 \), the term inside the last
square bracket in the above inequality is greater than \( \int_0^1 \hat{b} - \int_x^1 (1-x) \hat{b}_x = \int_0^1 \hat{b} + (1-x^*) \hat{b}(x^*) - \int_x^1 \hat{b} > 0 \) so that the above inequality produces a contradiction. This completes the proof of case 1.

**Case 2:** \( \phi \) has an odd number of interior zeros. We may assume that \( \phi > 0 \) on \((0, \alpha_0)\).

**Subcase (a):** \( E_2 \phi < 0 \). Since \( \phi_x(\beta_0) \leq 0 \) and \( \int_{\beta_0}^1 \phi < 0 \), we have, from (3.13),

\[
\frac{\phi_x(1) b_0 \lambda \ell}{\ell^2 (\lambda \ell + V_d)} \geq V_d \phi_x(1) \hat{b}(\beta_0) - \frac{\lambda \phi_x(0) [b_0 - \hat{b}(\beta_0)]}{\lambda \ell^2 + V_d \ell} + \eta_1 (\gamma_b + \lambda) \int_0^1 \phi < 0.
\]

Replacing \( \phi_x(1) \) by \( \phi_x(0) - \mathcal{T} E_2 \phi \) in the above inequality, simplifying, and using the facts that \( \phi_x(0) \geq 0, V_d + \lambda \ell \geq 0 \), and (3.8), we have

\[
0 > \frac{b_0 \lambda \ell + V_d \hat{b}(\beta_0) - \lambda \phi_x(0) [b_0 - \hat{b}(\beta_0)]}{\lambda \ell^2 + V_d \ell} + \eta_1 (\gamma_b + \lambda) \int_0^1 \phi
= \frac{(V_d + \lambda \ell) \hat{b}(\beta_0)}{\lambda \ell^{2} + V_d \ell} \phi_x(0) - \frac{b_0 \lambda \ell + V_d \hat{b}(\beta_0)}{\lambda \ell^{2} + V_d \ell} E_2 \phi + \eta_1 (\gamma_b + \lambda) \int_0^1 \phi
\geq \frac{b_0 \lambda \ell + V_d \hat{b}(\beta_0)}{\lambda \ell^{2} + V_d \ell} \omega (\lambda + \gamma_b) \int_0^1 \phi + \eta_1 (\gamma_b + \lambda) \int_0^1 \phi.
\]

Substituting in the definitions of \( \omega \) and \( \eta_1 \) and rearranging, we have

\[
0 > \left\{ \frac{(V_d + \lambda \ell \beta_0) \hat{b}(\beta_0) + (\lambda + 2 \gamma_b) \ell \int_0^1 \hat{b}}{b_0 V_d + (\lambda + 2 \gamma_b) \ell \int_0^1 \hat{b}} \right\} (\gamma_b + \lambda) \int_0^1 \phi.
\]

Since the term inside the parenthesis is non-negative, we have \( \int_0^1 \phi < 0 \), which from (3.8) implies that \( E_2 \phi > 0 \). This contradicts the subcase we are in.

**Subcase (b):** \( E_2 \phi > 0 \). Since \( \phi_x(\alpha_0) \leq 0 \) and \( \int_0^\alpha \phi > 0 \), we have, from (3.14),

\[
0 < \frac{-b_0 \phi_x(0) V_d}{\ell (\lambda \ell^2 + V_d \ell)} - \frac{\lambda \beta(\alpha_0) \phi_x(0)}{\lambda \ell^3 + V_d \ell} - \frac{V_d \phi_x(1) [\hat{b}(\alpha_0) - b_0]}{\lambda \ell^3 + V_d \ell^2} + \eta_0 (\gamma_b + \lambda) \int_0^1 \phi.
\]

Replacing \( \phi_x(0) \) by \( \phi_x(1) + \mathcal{T} E_2 \phi \) above and using the fact that \( \phi_x(1) \geq 0 \), we have

\[
0 < - \left[ \frac{b_0 V_d + \lambda \ell \hat{b}(\alpha_0) |\phi_x(1) + \mathcal{T} E_2 \phi|}{\lambda \ell^3 + V_d \ell} - \frac{V_d \phi_x(1) [\hat{b}(\alpha_0) - b_0]}{\lambda \ell^3 + V_d \ell^2} \right] \omega + \eta_0 (\gamma_b + \lambda) \int_0^1 \phi
\leq \left[ \frac{V_d b_0 + \lambda \ell \hat{b}(\alpha_0)}{\lambda \ell^3 + V_d \ell} \right] \omega + \eta_0 (\gamma_b + \lambda) \int_0^1 \phi
\leq \left\{ \frac{V_d b_0 + \lambda \ell \hat{b}(\alpha_0)}{b_0 V_d + (\lambda + 2 \gamma_b) \ell \int_0^1 \hat{b}} + \frac{(\lambda + 2 \gamma_b) \ell \int_0^\alpha \hat{b} - \lambda \ell \beta(\alpha_0) \hat{b}(\alpha_0)}{b_0 V_d + (\lambda + 2 \gamma_b) \ell \int_0^1 \hat{b}} \right\} (\gamma_b + \lambda) \int_0^1 \phi.
\]
Since \( V_d b_0 + \lambda \tilde{b}(\alpha_0) \geq 0 \), therefore if \( \lambda \leq 0 \), the terms inside the curly bracket are positive. If \( \lambda > 0 \), then since \( \alpha_0 < 1 \), the terms inside the curly bracket are also positive. Therefore, \( \int_0^1 \phi > 0 \) so that \( E_2 \phi < 0 \). This contradicts the subcase we are in. The proof of Lemma 3.2 is complete.

\[ \square \]

4. NON-EXISTENCE OF COMPLEX EIGENVALUES

The eigenvalue problem (2.7) is non-local and non-selfadjoint. Although we are unable to show that all its eigenvalues are real, we will, in this section, present strong numerical evidence that this is indeed the case.

We divide \([0, 1]\) into 1000 equal parts, discretize (2.7) and use Matlab to find the eigenvalues of the resulting matrix. We did this for \( b_0 \) in a wide range of values, and all 1000 eigenvalues were found to be real and negative. We also obtained asymptotic formulas for the eigenvalues as \( b_0 \to \infty \) and compared the results obtained from using these formulas with numerics in Table 1.

\begin{table}[h]
\centering
\caption{Comparison of 10 largest eigenvalues for \( b_0 = 500 \)}
\begin{tabular}{|c|c|c|}
\hline
Using formal asymptotic & Solving (2.7) numerically & Relative Error in \\%
\hline
-27986.970799 & -27948.659114 & 0.136891 \\
-22113.162113 & -22082.983561 & 0.136473 \\
-16930.389743 & -16907.269524 & 0.136560 \\
-12438.653688 & -12421.525704 & 0.137700 \\
-8637.953950 & -8625.854456 & 0.140074 \\
-5528.290528 & -5520.212489 & 0.146122 \\
-3109.63422 & -3104.763214 & 0.157580 \\
-1382.072632 & -1379.315927 & 0.199462 \\
-345.518158 & -344.655110 & 0.249784 \\
-1.800790 & -1.803155 & 0.131375 \\
\hline
\end{tabular}
\end{table}

In the next table, we document the eigenvalues when \( b_0 \) is small. Since the traveling cell solution develops a boundary layer at \( y = 0 \) as \( b_0 \to 0 \), we refine our mesh points to ensure that our numerical results are trustworthy.

\begin{table}[h]
\centering
\caption{Comparison of 10 largest eigenvalues for \( b_0 = 1 \)}
\begin{tabular}{|c|c|c|}
\hline
Using 2000 mesh points & Using 3000 mesh points & Relative Error in \\%
\hline
-64.26655 & -64.13063 & 0.212 \\
-54.20776 & -54.15408 & 0.099 \\
-42.88961 & -42.79822 & 0.214 \\
-35.90944 & -35.92078 & 0.032 \\
-26.76623 & -26.69850 & 0.254 \\
-22.98394 & -23.04107 & 0.248 \\
-16.25227 & -16.18816 & 0.396 \\
-14.97859 & -15.07460 & 0.637 \\
-11.98912 & -12.01627 & 0.226 \\
-0.18120 & -0.18239 & 0.652 \\
\hline
\end{tabular}
\end{table}

In conclusion, we believe that all the eigenvalues of (2.7) are real.
