FUNCTION REPRESENTATION
OF A NONCOMMUTATIVE UNIFORM ALGEBRA

KRZYSZTOF JAROSZ

(Communicated by N. Tomczak-Jaegermann)

Abstract. We construct a Gelfand type representation of a real noncommutative Banach algebra $A$ satisfying $\|f^2\| = \|f\|^2$, for all $f \in A$.

1. Introduction

A uniform algebra $A$ is a Banach algebra such that

$$\|f^2\| = \|f\|^2, \text{ for all } f \in A.$$  \hspace{1cm} (1.1)

The commutative, complex uniform algebras constitute the most classical class of Banach algebras, one which has been intensely studied for decades. It is well known that any such algebra is isometrically isomorphic with a subalgebra of $C_\mathbb{C}(X)$, the algebra of all continuous complex-valued functions defined on a compact set $X$ and equipped with the sup-norm topology. Hirschfeld and Želazko [6] proved that the assumption that the algebra is commutative is superfluous—commutativity already follows from (1.1). Algebras of analytic functions serve as standard examples of complex uniform algebras.

Commutative, real uniform algebras have also been studied for years [9]. Any such algebra $A$ is isometrically isomorphic with a real subalgebra of $C_\mathbb{C}(X)$ for some compact set $X$; furthermore, $X$ can often be divided into three parts $X_1, X_2, X_3$ such that $A|_{X_1}$ is a complex uniform algebra, $A|_{X_2}$ consists of complex conjugates of the functions from $A|_{X_1}$, and $A|_{X_3}$ is equal to $C_\mathbb{R}(X_3)$. Any commutative, real uniform algebra can be naturally identified with a real subalgebra of $C_\mathbb{C}(X, \tau) = \{ f \in C_\mathbb{C}(X) : f(\tau(x)) = \overline{f(x)} \text{ for } x \in X \}$, where $\tau : X \to X$ is a surjective homeomorphism with $\tau^2 = id_X$. In the case of real uniform algebras the condition (1.1) no longer implies commutativity; the four-dimensional algebra of quaternions serves as the simplest counterexample.

There has been very little study of noncommutative real uniform algebras. Only recently it was proved [1] that any such algebra is isomorphic with a real subalgebra of $C_\mathbb{H}(X)$, the algebra of all continuous functions defined on a compact set $X$ and taking values in the field $\mathbb{H}$ of quaternions. There is no simple theory of analytic functions of quaternion variables. The standard definition
Let $\Phi: A \to \mathbb{H}$ be a homomorphism of the group $\mathcal{M}$ onto a group of homeomorphisms of a compact set $X$. We define

$$C_{\mathbb{H}}(X, \Phi) \overset{df}{=} \{ f \in C_{\mathbb{H}}(X) : f \circ \Phi_T(x) = T \circ f(x) \text{ for } x \in X, T \in \mathcal{M} \}. $$

For a commutative real or complex uniform algebra $A$ the standard way to represent $A$ as a subalgebra of $C_{\mathbb{C}}(X)$ is to consider the space $X = \mathfrak{M}(A)$ of all complex-valued linear-multiplicative functionals and use the Gelfand transformation:

$$A \ni a \mapsto \hat{a} \in C(X) : \hat{a}(x) = x(a).$$

We first need an easily verifiable elementary description of isomorphisms of the four-dimensional real algebra $\mathbb{H}$.

**Proposition 1.** A surjective map $T: \mathbb{H} \to \mathbb{H}$ is linear (over the field of real numbers) and multiplicative if and only if

$$(2.1) \quad T(a, b, c, d) = \begin{bmatrix} 1 & 0 & 0 & \mathbf{M} \\ 0 & 1 & 0 & \mathbf{M} \\ 0 & 0 & 1 & \mathbf{M} \\ 0 & 0 & 0 & \mathbf{M} \end{bmatrix}, \text{ for } a + bi + cj + dk \in \mathbb{H},$$

where $\mathbf{M}$ is an isometry of 3-dimensional Euclidean space $\mathbb{R}^3$ preserving the orientation of that space. The space of all such maps forms a 3-dimensional compact connected group, which we will denote by $\mathcal{M}$.

We should also notice that if $A$ is a real algebra and $F: A \to \mathbb{H}$ is a multiplicative functional such that $\dim(F(A)) = 2$, then $F(A)$ is isomorphic with $\mathbb{C}$ and the set $\{T \circ F : T \in \mathcal{M}\}$ can be identified with the unit sphere in $\mathbb{R}^3$. Indeed to define an isometry $T$ on $F(A)$ we just have to decide which unit vector of the form $bi + cj + dk$ is to be the image of the imaginary unit of $F(A)$.

**Definition 1.** We say that $A \subset C(X)$ separates the points of $X$ if for any $x_1, x_2 \in X$ there is $f \in A$ such that $f(x_1) \neq f(x_2)$. We say that $A \subset C(X)$ strongly separates the points of $X$ if for any $x_1, x_2 \in X$ there is $f \in A$ such that $f(x_1) \neq f(x_2) = 0$.

**Definition 2.** A real algebra $A$ is fully noncommutative if any nonzero linear and multiplicative functional $F: A \to \mathbb{H}$ is surjective.

Notice that $A$ is not fully noncommutative if $\{F(a) : a \in A\}$ is isomorphic with $\mathbb{R}$ or with $\mathbb{C}$ for some $\mathbb{H}$-valued multiplicative functional $F$ on $A$.

**Definition 3.** Let $\Phi: \mathcal{M} \to Hom(X) : \Phi(T) = \Phi_T$ be a homomorphism of the group $\mathcal{M}$ onto a group of homeomorphisms of a compact set $X$. We define

$$C_{\mathbb{H}}(X, \Phi) \overset{df}{=} \{ f \in C_{\mathbb{H}}(X) : f \circ \Phi_T(x) = T \circ f(x) \text{ for } x \in X, T \in \mathcal{M} \}. $$

For a commutative real or complex uniform algebra $A$ the standard way to represent $A$ as a subalgebra of $C_{\mathbb{C}}(X)$ is to consider the space $X = \mathfrak{M}(A)$ of all complex-valued linear-multiplicative functionals and use the Gelfand transformation:

$$A \ni a \mapsto \hat{a} \in C(X) : \hat{a}(x) = x(a).$$
For a real algebra $A$ and for any $x \in \mathfrak{M}(A)$, also the complex conjugate $\bar{x} = \tau(x)$ of $x$ is an element of $\mathfrak{M}(A)$, hence the representation of $A$ as a subalgebra of $C_C(X, \tau)$. An important feature of such a representation is that $\hat{\tau}$ maps the set of invertible elements of $A$ exactly onto the subset of $\hat{A}$ consisting of functions that do not vanish on $X$. We will construct a similar representation for a noncommutative uniform algebra.

**Theorem 1.** Assume $A$ is a real uniform algebra. Then there is a compact set $X$ and an isomorphism $\Phi : \mathcal{M} \to \text{Hom}(X)$ such that $A$ is isometrically isomorphic with a subalgebra $\hat{A}$ of $C_\mathbb{H}(X, \Phi)$. Furthermore $a \in A$ is invertible if and only if the corresponding element $\hat{a} \in \hat{A}$ does not vanish on $X$.

If $A$ is fully noncommutative, then $\hat{A} = C_\mathbb{H}(X, \Phi)$.

We have obvious candidates for $X$, $\Phi$, and the map $^\wedge$:

$$X \overset{df}{=} \mathfrak{M}_\mathbb{H}(A) = \text{quaternion-valued real-linear and multiplicative functionals} \quad (2.3) \quad \Phi_T(x) \overset{df}{=} T \circ x, \quad \hat{a}(x) \overset{df}{=} x(a).$$

It is clear that the map $^\wedge$ is a homomorphism of $A$ into $C_\mathbb{H}(X, \Phi)$. We need to show that it is an isometry, that it preserves the set of noninvertible elements, and that $\hat{A} = C_\mathbb{H}(X, \Phi)$ in the fully noncommutative case. So without loss of generality we may assume that $A$ is separable, or equivalently countably generated.

Before proving the theorem it will be useful to notice that for $x \in X$ we may encounter exactly three distinct cases: the set $\{T \circ x : T \in \mathcal{M}\}$ may be

- equal to the singleton $\{x\}$ if $x(A) = \mathbb{R}$, or
- homeomorphic with the unit sphere in $\mathbb{R}^3$ if $x(A)$ is a 2-dimensional commutative subalgebra of $\mathbb{H}$ isomorphic with $\mathbb{C}$, or
- homeomorphic with $\mathcal{M}$ if $x(A) = \mathbb{H}$.

Consequently the set $\mathfrak{M}_\mathbb{H}(A)$ can be divided into three parts $X_1, X_2, X_3$:

- $X_1 = \{x \in X : T \circ x = x \text{ for all } T \in \mathcal{M}\} = \{x \in X : x(A) = \mathbb{R}\}$; that set is equal to the subset of $X$ consisting of the points where all the functions from $A$ are real valued;
- $X_2 = \{x \in X : \text{dim } x(A) = 2\}$; that set is a union of disjoint copies of the unit sphere in $\mathbb{R}^3$, and the algebra $\hat{A}$ restricted to $X_1 \cup X_2$ is commutative;
- $X_3 = \{x \in X : x(A) = \mathbb{H}\}$; that set is a union of disjoint copies of $\mathcal{M}$ and the algebra $\hat{A}$ restricted to $X_3$ is fully noncommutative.

That is analogous to the commutative case when a real-linear multiplicative functional $x$ takes only real values if $\tau(x) = x$, or takes all complex values if $\tau(x) \neq x$ and the set $\mathfrak{M}(A)$ can be divided into just two parts.

Put

$$A_R = \left\{ a \in A : \hat{a} \text{ is constant on } X_1 \cup X_2 \text{ and on } \{T \circ x : T \in \mathcal{M}\} \text{ for each } x \in X_3 \right\}$$

and

$$\hat{A}_R = \{ \hat{a} \in C_\mathbb{H}(X) : a \in A \}.$$

We prove the theorem in several short steps; the steps also provide a much more detailed description of the representation of $A$:

1. the map $^\wedge$ defined by (2.3) is injective and $A$ is semisimple;
(2) \( \hat{A}_R = \left\{ f \in C_R(X) : f \text{ is constant on } X_1 \cup X_2 \right\} \); furthermore \( \|a\| = \|\hat{a}\| \) for any \( a \in A_R \);

(3) \( X_1 \cup X_2 \) is a weak peak set for \( \hat{A} \), so any function from \( \hat{A}_{|X_1\cup X_2} \) defined by \( \left\{ f_{|X_1\cup X_2} \in C(X_1 \cup X_2) : f \in \hat{A} \right\} \) has a norm-preserving extension to a function in \( \hat{A} \); \( \mathfrak{M}(\hat{A}_{|X_1\cup X_2}) = X_1 \cup X_2 \);

(4) \( \{ f \in C_R(X, \Phi) : f(x) = 0 \text{ for } x \in X_1 \cup X_2 \} \subseteq \hat{A} \);

(5) \( \hat{A} = \left\{ f \in C_R(X, \Phi) : f_{|X_1\cup X_2} \in \hat{A}_{|X_1\cup X_2} \right\} \);

(6) the map \( ^\wedge \) is an isometry and \( \hat{A}_{|X_1\cup X_2} \) is a complete algebra;

(7) any noninvertible element of \( A \) is contained in a kernel of a functional from \( \mathfrak{M}_R(A) \); \( \hat{A} = C_R(X, \Phi) \) if \( A \) is fully noncommutative.

The first part follows from Theorem 3 of [1]. We provide an independent proof here for completeness. We will need the following special case of the main result of [2].

**Theorem 2** (Aupetit-Zemanek). Let \( A \) be a real Banach algebra with unit. If \( \lim \sqrt{\|\alpha^n\|} = \|\alpha\| \) for all \( \alpha \) in \( A \), then for every irreducible representation \( \pi : A \to L(E) \), the algebra \( \pi(A) \) is isomorphic with its commutant \( C_\pi \) in the algebra \( L(E) \) of all linear transformation on \( E \).

**Proof.** Part 1. Since the commutant \( C_\pi \) is a normed real division algebra ([3], p. 127) it is isomorphic with \( \mathbb{R}, \mathbb{C}, \) or \( \mathbb{H} \). Let \( X \) be the set of all irreducible representations of \( A \); for \( x \in X \) and \( a \in A \) put \( \hat{a}(x) = x(a) \in \mathbb{H} \). The map \( ^\wedge \) is an isomorphism of \( A \) into the algebra of \( \mathbb{H} \)-valued functions on \( X \). Let \( \sigma \) be the strongest topology on \( X \) such that all the functions \( \hat{a}, a \in A \), are continuous. Assume \((X, \sigma)\) is not compact and let \( x_0 \) be a point from \( \beta X \setminus X \); the operator \( A \ni a \to \hat{a}(x_0) \in \mathbb{H} \) is an irreducible representation on \( A \), so \( x_0 \in X \), a contradiction.

To show that \( ^\wedge \) is injective we need to show that for any \( 0 \neq a \in A \) there is an irreducible representation \( \pi \) with \( \pi(a) \neq 0 \). Fix \( 0 \neq a \in A \) and let \( A_a \) be the closed subalgebra of \( A \) generated by all the elements of the form \( q(a) \), where \( q \) is a rational function with real coefficients and with poles outside the spectrum of \( a \). Notice that \( A_a \) is a commutative uniform algebra such that \( \text{rad}A_a = \{ 0 \} \). If \( b \in A_a \cap A_a^{-1} \), then \( b^{-1} \) as given by a rational function is in \( A_a \); that means that \( A_a^{-1} \cap A_a = A_a^{-1} \). Hence by [11, p. 476], \( A_a \cap \text{rad}A = \text{rad}A_a = \{ 0 \} \), so \( a \notin \text{rad}A \) and, since \( a \) was arbitrary, \( A \) is semisimple.

Part 2. Put

\[
\mathcal{R} = \left\{ (fg - gf)^2 \in C_R(X) : f, g \in \hat{A} \right\}.
\]

For arbitrary quaternions \( w_p = a_p + b_p i + c_p j + d_p k, p = 1, 2 \) we have

\[
(w_1 w_2 - w_2 w_1)^2 = (2(b_1 c_2 - b_2 c_1)ij + 2(b_1 d_2 - b_2 d_1)ik + 2(c_1 d_2 - c_2 d_1)jk)^2
\]

\[
= 4((b_1 c_2 - b_2 c_1)k - (b_1 d_2 - b_2 d_1)j + (c_1 d_2 - c_2 d_1)i)^2
\]

\[
= -4 \left( (b_1 c_2 - b_2 c_1)^2 + (b_1 d_2 - b_2 d_1)^2 + (c_1 d_2 - c_2 d_1)^2 \right)
\]

\[
\in C_R(X),
\]

so \( \mathcal{R} \) contains only real-valued functions. Let \( \sim \) be an equivalence relation on \( X \) defined by

\[x_1 \sim x_2 \text{ iff } h(x_1) = h(x_2) \text{ for all } h \in \mathcal{R},\]
let $X_0 = X_{/\sim}$ be the quotient space, and let $\pi : X \to X_0$ be the natural projection. For $x \in X$ there is a function in $\mathcal{R}$ not vanishing at $x$ if and only if $x \in X_3$; furthermore on $X_3$ we have $x_1 \sim x_2$ if and only if $\ker x_1 = \ker x_2$, or equivalently if and only if $\{T \circ x_1 : T \in \mathcal{M}\} = \{T \circ x_2 : T \in \mathcal{M}\}$. By the Stone-Weierstrass Theorem $A_R$ can be identified with a dense subset of $C_R(X_0)$. We shall show that in fact it is equal to the entire $C_R(X_0)$.

$A_R$ is a commutative real uniform algebra, so it is isometric with a closed subalgebra of $C_R(\mathfrak{M}(A_R))$; $X_0$ can be naturally identified with a closed subset of $\mathfrak{M}(A_R)$. Assume $X_0 \neq \mathfrak{M}(A_R)$, and let $y_0 \in \mathfrak{M}(A_R) \backslash X_0$. Since $\mathfrak{M}(A_R)$ is equipped with the weak * topology, there are $a_1, \ldots, a_n \in A_R$ such that $\hat{a}_1(y_0) = \ldots = \hat{a}_n(y_0) = 0$ and $\max \{ |\hat{a}_j(y)| : j = 1, \ldots, n \} \geq 1$ for any $y \in X_0$. Hence $\hat{a}_0 = \hat{a}_1^2 + \ldots + \hat{a}_n^2 \in A_R$ is strictly positive on $X_0 = X_{/\sim}$, and since $A$ is semisimple, $a_0$ is an invertible element of $A_R \subset A$ contrary to the fact that it is in the kernel of the functional $y_0$. The contradiction shows that $X_0 = \mathfrak{M}(A_R)$ and consequently $A_R = C_R(X_0)$. Assume there is $a \in A_R$ such that $\|a\| = \|\hat{a}\|$. Since $\|\hat{a}^n\| \to 0$ while $\|a^n\| = 1$ it follows that the range of $^\wedge$ is not complete; that contradiction shows that $^\wedge$ is an isometry on $A_R$.

Part 3. We recall that a subset $K$ of the maximal ideal space of a function algebra is called a weak peak set if for any open neighborhood $U$ of $K$ there is a function $f$ in that algebra such that $f(x) = 1 = |f| > |f(x')|$ for any $x \in K$ and any $x' \notin U$. Since $C_R(X_0) \simeq A_R \subset A$ it follows that $X_1 \cup X_2$ is a weak peak set. Assume $a \in A$ with $\sup \{ |\hat{a}(x)| : x \in X_1 \cup X_2 \} = 1$. Since $\mathcal{M}$ consists of isometries, $\frac{1}{\max \{1, |a|\}}$ is constant on the sets $\{ T \circ x : T \in \mathcal{M} \}$ for $x \in X_3$ as well as on the set $X_1 \cup X_2$. Hence $\frac{1}{\max \{1, |a|\}} \in 1 \hat{A}$ so $\hat{a} \cdot \frac{1}{\max \{1, |a|\}} \in 1 \hat{A}$; that function coincides with $\hat{a}$ on $X_1 \cup X_2$ and has norm 1. It is important to notice for further reference that since $^\wedge$ is an isometry on $A_R$ we have $\frac{1}{\max \{1, |a|\}}$ is a norm-preserving extension of $a$ with respect to the spectral norm but also with respect to the original norm of the algebra $A$.

The maximal ideal space of $A|_{X_1 \cup X_2}$ is equal to $X_1 \cup X_2$ since any linear and multiplicative functional on $A|_{X_1 \cup X_2}$ gives a functional on $A$ as well.

Part 4. Fix $x_0 \in X_3$ and let $f_1, f_2, f_3, f_4 \in A$ be such that $f_1(x_0) = 1, f_2(x_0) = i, f_3(x_0) = j, f_4(x_0) = k$. Let $U_0$ be an open neighborhood of $x_0$ such that $|f_p(x) - f_p(x_0)| < 1/4$ for $x \in U_0$ and $p = 1, 2, 3, 4$. Let $g_0 \in C_\mathbb{H}(X, \Phi)$ and assume the support of $g_0$ is contained in $V_0 \overset{df}{=} \pi^{-1}(\pi(U_0))$. For any $x \in U_0$, the numbers $f_1(x), f_2(x), f_3(x), f_4(x)$ can be seen as linearly independent vectors in $\mathbb{H} \simeq \mathbb{R}^4$, so there are unique real-valued functions $h_p$ defined on $U_0$ such that

$$g_0(x) = \sum_{p=1}^{4} h_p(x) f_p(x) \quad \text{for } x \in U_0. \tag{2.4}$$

Let $x \in U_0$ and let $x' = T \circ x$ be another point of $\pi^{-1}(\pi(x))$, where $T \in \mathcal{M}$. By the definition of $C_\mathbb{H}(X, \Phi)$ we have

$$g_0(x') = T \circ g_0(x) = \sum_{p=1}^{4} h_p(x) T \circ f_p(x) = \sum_{p=1}^{4} h_p(x) f_p(x').$$

Hence the functions $h_p, p = 1, 2, 3, 4$ are constant on sets of the form $\pi^{-1}(\pi(x))$ and consequently can be naturally extended to $V_0$; furthermore, they can be extended...
to the entire set $X$ by assigning value zero outside $V_0$. Since the coefficients with respect to a fixed basis in $\mathbb{R}^2$ are continuous functions of a vector in $\mathbb{R}^3$, the functions $h_{p,p}$, $p = 1, 2, 3, 4$ belong to $A_R \subset A$. Hence $g_0 \in A$.

We proved that for any point $x_0$ in $X$ there is a neighborhood $V_0$ of $\pi^{-1}(x)$ such that $A_{V_0} = C_{\mathbb{R}^3}(X, \Phi)_{V_0}$. Let $V_s = \pi^{-1}(\pi(U_s)), s \in S$ be an open cover of $X$ consisting of such sets. Since $A$ is separable and $X_3$ is a subset of its dual space equipped with the weak * topology, $X_3$ is metrizable and consequently paracompact. Let $\sum_{s \in S} \alpha_s = 1$ be a locally finite partition of unity in $C_\mathbb{R}(X_3)$ subordinated to the cover $\pi(U_s), s \in S$ of $X_3$ ([4], page 375). For any $g \in C_{\mathbb{R}}(X, \Phi)$ such that $g(x) = 0$ for $x \in X_1 \cup X_2$, we have $g(x) = \sum_{s \in S} \alpha_s \pi(x)g(x)$ where $\text{supp} \alpha_s \pi g \subset V_s$, so $g \in A$.

Part 5. Assume $f \in C_\mathbb{R}(X, \Phi)$ is such that $f_{|X_1 \cup X_2} \in \hat{A}_{|X_1 \cup X_2}$. Let $g \in A$ be such that $g_{|X_1 \cup X_2} = f_{|X_1 \cup X_2}$. Since $f - g \in \{f \in C_\mathbb{R}(X, \Phi) : f(x) = 0$ for $X_1 \cup X_2\}$ by the previous step, $f = g + (f - g) \in A$.

Part 6. Put $I = \{a \in A : \hat{a}(x) = 0$ for $x \in X_1 \cup X_2\}$ and let $B = A/I$ be the quotient algebra. Notice that $B$ is a commutative Banach algebra with $\mathcal{M}(B) = X_1 \cup X_2$. Assume there is $a + I \in B$ such that $\|a + I\| = \|a\| > 2$ and $\|\hat{a}\| \leq 1$. By Part 3 we may assume that $\|\hat{a}\| = \|\hat{a}_{|X_1 \cup X_2}\|$. Suppose that $\|a^2 + I\| < 1$ so that there is $g \in I$ with $\|a^2 + g\| < 1$. By Part 3 again we may assume that $\hat{g}^2 + \hat{g}$ is smaller than 1 on $X$ and consequently $\|g\| = \|\hat{g}\| < 2$. We have $\|a^2 + g\| < 1, \|g\| < 2, \|a^2\| = 4$, which is impossible. The above proves that $\|b^2\| \geq \frac{1}{4}\|b\|^2$, for all $f \in B$.

So $B$ is isomorphic with a complete uniform algebra which must be equal to $A_{|X_1 \cup X_2}$; by the same arguments as at the end of Part 3 we conclude that $\wedge$ is in fact an isometry.

Part 7. This is an obvious consequence of Part 5 since $\mathcal{M}(\hat{A}_{|X_1 \cup X_2}) = X_1 \cup X_2$. \hfill $\square$

**Corollary 1.** Assume $A$ is a fully noncommutative closed subalgebra of $C_\mathbb{H}(Y)$. Then $A = C_\mathbb{H}(Y)$ if and only if $A$ strongly separates the points of $Y$.

We do not assume here that $A$ contains all constant functions; if we assume that the constant functions $i, j, k$ are in $A$, then the above version of the Stone-Weierstrass Theorem easily follows from the following fact: $f \in A$ implies that $\text{Re} f = (f - ifj - jfk - kfk)/4 \in A$ ([7]).

For a fully noncommutative real uniform algebra $A$, its maximal ideal space $\mathcal{M}_{\mathbb{R}}(A)$ consists of disjoint copies of $\mathcal{M}$ and is locally homeomorphic with a Cartesian product of $\mathcal{M}$ with another set. Quite often we also have a global decomposition: $\mathcal{M}_{\mathbb{R}}(A) = Y \times \mathcal{M}$. However, such a global decomposition cannot always be achieved, not even its analog in the commutative case. In the commutative case when $A \subset C_\mathbb{C}(X, \tau)$ and we can divide $X$ into three parts $X_1, X_2$, and $X_3$ such that $A_{|X_1}$ is a complex algebra, $A_{|X_2}$ consists of complex conjugates of the functions from $A_{|X_1}$, and $A_{|X_3}$ is equal to $C_\mathbb{R}(X_3)$. It is easy to select $X_3 = \{x \in X : \tau(x) = x\}$; we may also easily select one point from each equivalence class $x_1 \sim x_2$ iff $\tau(x_1) = x_2$ to get $X_1$ and we can form $X_2$ from the remaining points. However we may not be able to make the sets $X_1, X_2$ closed, so $A_{|X_1}, A_{|X_2}$ may not be uniform algebras;
see for example $A = \left\{ f \in C(C(S^1)) : f(e^{it}) = \overline{f(e^{i(t+\pi)})} \text{ for } 0 \leq t \leq \pi \right\}$ where $S^1$ is a unit circle. This is the reason we represent a real commutative uniform algebra as a subalgebra of $C(C(X,\tau))$ rather than, what may seem more appealing, a direct sum of $A_{|X_1}, A_{|X_2},$ and $A_{|X_3}$.

We proved that the algebra $\mathbb{H}$ has the following property:

Any subalgebra $A$ of $C\mathbb{H}(X) = C\mathbb{R}(X) \otimes \mathbb{H}$ that strongly separates the points of $X$ and such that $\{ f(x) : x \in X \} = \mathbb{H}$ for all $x \in X$ is equal to $C\mathbb{H}(X)$.

We also know (Stone-Weierstrass Theorem) that the algebra $\mathbb{R}$ has the same property. It would be interesting to find other algebras with the same property.

ACKNOWLEDGMENT

The author would like to thank S. H. Kulkarni for his hospitality and for several stimulating discussions during the author’s visit at the Indian Institute of Technology.
