CANTOR SINGULAR CONTINUOUS SPECTRUM FOR OPERATORS ALONG INTERVAL EXCHANGE TRANSFORMATIONS

M. COBO, C. GUTIERREZ, AND C. R. DE OLIVEIRA

(Communicated by Joseph A. Ball)

Abstract. It is shown that Schrödinger operators, with potentials along the shift embedding of Lebesgue almost every interval exchange transformations, have Cantor spectrum of measure zero and pure singular continuous for Lebesgue almost all points of the interval.

1. Introduction and main result

In [7] the spectrum $\sigma(H_{\omega})$ of the discrete Schrödinger operators

$$H_{\omega} : l^2(\mathbb{Z}) \to l^2(\mathbb{Z}),$$

(1)

$$(H_{\omega}\psi)_j := \psi_{j+1} + \psi_{j-1} + \omega_j \psi_j,$$

with $\omega = (\omega_j)_{j \in \mathbb{Z}}$ a sequence of real numbers (the so-called potential) modulated along the shift embedding of interval exchange transformations (iets) [10, 11], was investigated. There the authors proved the presence of the pure singular continuous spectrum for $H_{\omega}$, for the shift associated with a dense set of iets, where the potential $\omega$ corresponds to the itinerary of the orbit of a.e. $x$ in the interval (from here on, a.e. with no specification means almost everywhere with respect to Lebesgue measure).

In this work we go a step further by showing that the above mentioned results of [7] hold for Lebesgue almost every iets. The proof of absence of eigenvalues involves a rather different argument, mainly the Rauzy induction map. As a byproduct of our a.e. results, which are summarized in Theorem 1 below, there is a set of interesting results in the literature ready to be applied, which leads to Cantor spectrum of zero Lebesgue measure; see Corollary 1.

Interval exchanges. Let us recall some notation and a description of the iets necessary to state and prove our results.

Given a semi-open interval $[a, b)$ and a vector $\lambda = (\lambda_1, \lambda_2, \ldots, \lambda_n)$ in $\mathbb{R}_+^n$ (i.e., all entries are positive) such that $\lambda_1 + \lambda_2 + \cdots + \lambda_n = b - a$, we consider the partition of $[a, b)$ in the $n$ consecutive semi-open intervals

$I_1 := [a, a_1), I_2 := [a_1, a_2), \ldots, I_n := [a_{n-1}, b)$

whose lengths are respectively $\lambda_1, \lambda_2, \ldots, \lambda_n$. Let $\pi$ be a permutation of the symbols \{1, 2, $\ldots$, n\}. An iet $E : [a, b) \to [a, b)$ is associated to the pair $(\pi, \lambda)$ by exchanging the positions of the intervals $I_i$ according to the permutation $\pi$, in such a way that the interval in the $t^{th}$ position, $I_t$, is translated to the $\pi(t)^{th}$ position (from left to right). In this way the transformation obtained is of the form

$$E(x) = x + d_i, \quad x \in I_i, \quad i = 1, 2, \ldots, n,$$

for some displacements $d_1, \ldots, d_n$.

In this work we consider mostly iets of the form $E : [0, b) \to [0, b)$, $b > 0$. An iet $E$ is normalized if it is defined in the interval $[0, 1)$. The set of all normalized iets is parameterized in the following way. Let $\Delta^{n-1}$ denote the standard simplex of $\mathbb{R}^n$,

$$\Delta^{n-1} := \{(l_1, l_2, \ldots, l_n) \in \mathbb{R}^n_+ : l_1 + l_2 + \cdots + l_n = 1\}.$$

If $P_n$ is the set of all permutations of the symbols \{1, 2, $\ldots$, n\}, then it is usual to identify the product $P_n \times \Delta^{n-1}$ with the set of all normalized interval exchanges of $n$ intervals. Let us denote by $G_n$ the set of irreducible permutations in $P_n$, i.e., those permutations $\pi$ for which $\pi(\{1, 2, \ldots, k\}) \neq \{1, 2, \ldots, k\}$ unless $k = n$.

For a fixed permutation $\pi \in G_n$ we denote by $E(\pi)$ the set of all normalized iets with permutation $\pi$. We identify the metric spaces $\Delta^{n-1}$ and $E(\pi)$ by the homeomorphism $\Delta^{n-1} \ni \lambda \mapsto E_\lambda := (\pi, \lambda)$.

Let $\Sigma_n := \{1, 2, \ldots, n\}^\mathbb{Z}$. Associated to the orbit of $x$ by $E_\lambda$ there is the so-called itinerary of $x$, $\omega_\lambda(x)$, which is an element of $\Sigma_n$ and which is given by the natural encoding of the $E_\lambda$-orbit of $x$ by assigning to each entry of this orbit the suffix $i$ of the interval $I_i$ which contains it. Set

$$\Omega_\lambda = \text{closure } \{\omega_\lambda([0, 1])\}$$

in $\Sigma_n$, so that $\Omega_\lambda$ with the left shift dynamics is a subshift over the alphabet \{1, 2, $\ldots$, n\}.

In the next theorem we will consider the $(n-1)$-dimensional Lebesgue measure in $\Delta^{n-1} \cong E(\pi), \pi \in G_n$. We also recall that a nonempty set in a metric space is a Cantor set if it is closed with empty interior and no isolated points.

Let us fix an irreducible permutation $\pi \in G_n$ and an arbitrary injective map $V : \{1, 2, \ldots, n\} \to \mathbb{R}$. For any $\omega \in \Sigma_n$ consider the potential $V(\omega) := (V(\omega_j))_{j \in \mathbb{Z}}$ and the operator $H_{V(\omega)}$ as in (1).

**Theorem 1.** There is a subset $\mathcal{F} \subset E(\pi)$ of full Lebesgue measure such that, for each $E_\lambda \in \mathcal{F}$, the spectrum of the corresponding Schrödinger operator (1) with potential $V(\omega_\lambda(x))$ is a Cantor set of zero (Lebesgue) measure and pure singular continuous for a.e. $x \in [0, 1)$.

We recall that for $n = 2$ and $\pi(1, 2) = (2, 1)$ there is only one discontinuity point $a_1 \in [0, 1)$ and the system is reduced to rotations of the circle by the angle $(1 - a_1)$. In this case the potentials $\Omega_E$ are the Sturmian sequences [1, 5], which include the well-known Fibonacci substitution sequence [14, 17]. Hence, the potentials generated by iets are natural generalizations of Sturmian potentials, one of the standard models of one-dimensional quasicrystals. We refer the reader to [7] for additional comments and to [6], as well as references therein, for related examples of Cantor zero measure spectrum.

We close this section with an open question we have found interesting. Although almost all iets are minimal and uniquely ergodic [13, 18], there are cases of minimal
jets with more than one ergodic component (\(n/2\) is an upper bound for the number of ergodic probability measures \([11, 13]\)), so it is natural to ask if the characterization of the spectrum in Theorem 1 holds in such cases.

2. Some related results

The proof of Theorem 1 will be reduced to the proof that, given an irreducible permutation \(\pi \in G_n\), for almost every iet \(E_\lambda \in E(\pi)\), the corresponding Schrödinger operators \(H_{V(\omega(\lambda)(x))}\) have no eigenvalues for Lebesgue almost every \(x \in [0, 1)\). In this section we clarify this statement and the next sections are devoted to the related proof of the absence of eigenvalues.

Consider a finite alphabet \(A\) and let \(W\) be the set of finite words in this alphabet. If \(B \in W\) we denote by \(|B|\) its length. Consider a subshift \(\Omega\) over \(A\) (the dynamics is always given by the left shift) and, for a given word \(B \in W\), let us denote by

\[
V_B = V_B(\Omega) = \{\omega \in \Omega : \omega(1) \cdots \omega(|B|) = B\},
\]

the cylinders. For each invariant probability measure \(\mu\) on \(\Omega\), set

\[
\eta_\mu(n) = \min\{\mu(V_B) : B \in W, |B| = n\}.
\]

In [2, 3] Boshernitzan introduced the following condition (which was later called condition (B) in [6]): the subshift \(\Omega\) satisfies condition (B) if there exists an ergodic probability measure \(\mu\) on \(\Omega\) with

\[
(B) \quad \limsup_{n \to \infty} n \eta_\mu(n) > 0.
\]

This condition was shown by Boshernitzan [4] to imply unique ergodicity for minimal subshifts and, in the particular case of jets, was previously done by Veech [19]. Boshernitzan [4] proved

Theorem 2. Let \(\pi \in G_n\). Then for Lebesgue almost every \(\lambda \in \Delta^{n-1}\) the subshift \(\Omega_\lambda\) satisfies condition (B).

Then, Veech [18] and Masur [13] obtained the result that \(E_\lambda\) is uniquely ergodic (and, in particular, minimal) for a.e. \(\lambda \in \Delta^{n-1}\).

Recall also the following basic result:

Lemma 1 ([10]). If \(E_\lambda\) is minimal, then \(\Omega_\lambda\) is a minimal subshift, i.e., every \(\omega \in \Omega_\lambda\) has dense orbit in \(\Omega_\lambda\).

With respect to the spectrum of discrete Schrödinger operators, the following important result was proved in [6]:

Theorem 3. Let \(\Omega\) be a minimal subshift which satisfies condition (B). If \(\Omega\) is aperiodic, then there exists a Cantor set \(\Sigma \subset \mathbb{R}\) of Lebesgue measure zero so that the spectrum \(\sigma(H_\omega) = \Sigma\) for every \(\omega \in \Omega\).

It is well known that minimality implies that the spectrum (as a set) is the same for all elements in the hull \(\Omega\); by combining this with Theorem 3 and the constancy of the absolutely continuous spectrum [12], for a fixed injective map \(V : \{1, 2, \ldots, n\} \to \mathbb{R}\) we summarize some important known results in

Corollary 1. Let \(\pi \in G_n\). There is a subset \(\mathcal{L} \subset E(\pi)\) of full Lebesgue measure so that:
(i) for each $E_\lambda \in \mathcal{L}$ the spectrum of $H_V(\omega)$ in (1) is the same for all $\omega \in \Omega_\lambda$, and it is a Cantor set of zero Lebesgue measure;

(ii) for each $E_\lambda \in \mathcal{L}$ the corresponding Schrödinger operators (1) with potentials $V(\omega_\lambda(x))$ have no absolutely continuous spectrum for all $x \in [0, 1)$.

Therefore in order to prove Theorem 1 it is enough to show that, given $\pi \in G_n$, there is a set $\mathcal{P} \subset E(\pi)$ of full Lebesgue measure so that for each $E_\lambda \in \mathcal{P}$ the corresponding Schrödinger operators $H_V(\omega_\lambda(x))$ have no eigenvalues for Lebesgue almost every $x \in [0, 1)$; thus only a singular continuous spectrum remains. Then the set $\mathcal{F}$ in Theorem 1 can be defined by the intersection of this set $\mathcal{P}$ with $\mathcal{L}$.

An important tool to exclude eigenvalues for a given operator $H_\omega$, $\omega \in \Sigma_n$, is the Delyon-Petritis [8] version of an argument of Gordon [9], by means of suitable local word repetitions.

**Theorem 4** ([8]). If for given $\omega \in \Sigma_n$ there exists a sequence $k_i \to \infty$ such that

$$\omega_{j-k_i} = \omega_j = \omega_{j+k_i},$$

for all $1 \leq j \leq k_i$, then the Schrödinger operator $H_\omega$ in (1) has no eigenvalues.

Given an irreducible permutation $\pi$, the idea is to show that, for almost all $\lambda \in \Delta^{n-1}$, Theorem 4 applies to $H_\omega$, $\omega = \omega_\lambda(x)$, with $x$ in a set of total Lebesgue measure over $[0, 1)$. In other words, we have to prove that for almost all $x \in [0, 1)$ there is a sequence of natural numbers $r_k \to \infty$ such that the itinerary of $x$ associated to $[-r_k, 2r_k]$ (i.e., the itinerary of the finite orbit $E^{-r_k}_\lambda(x), E^{-r_k+1}_\lambda(x), \ldots, E^{2r_k}_\lambda(x)$) is of the form

$$\omega_0 \omega_1 \ldots \omega_{r_k} \omega_0 \omega_1 \ldots \omega_{r_k} \omega_0 \omega_1 \ldots \omega_{r_k}, \quad \omega_i \in \{1, 2, \ldots, n\}.$$

To prove this statement (which is Proposition 1 of Section 4) we will use the well-known Rauzy Renormalization Operator in the space of interval exchange transformations. In the next section we will introduce the appropriate definitions and necessary results.

### 3. Rauzy’s renormalization

Let $E : [a, b) \to [a, b)$ be a minimal iet such that $E = (\lambda, \pi)$ for some $\pi \in G_n$ and $\lambda \in \mathbb{R}^n_+$. Let $J := [c, d)$ be a proper subinterval of $[a, b)$. Let us denote by $E_J$ the Poincaré’s first return map of $E$ to the interval $J$, that is, for $x \in J$, $E_J(x)$ is given by the first point in the positive orbit of $x$ (by $E$) that steps into the interval $J$. By the minimality of $E$, the map $E_J$ is again an iet of $p$ intervals with $p \geq n$. We will be interested only in the case $p = n$; in this way $E_J$ will be associated to a pair $(\lambda', \pi')$ with $\lambda' \in \mathbb{R}^n_+$ and $\pi' \in G_n$. The iet $E_J$ will be called the induced map of $E$ onto the interval $J$. Let $I_1, I_2, \ldots, I_n$ be the intervals of continuity of $E_J$. For each $1 \leq k \leq n$ there exists an integer $r_k > 0$ such that

$$E(I_k), E^2(I_k), \ldots, E^{r_k}(I_k)$$

are all intervals disjoint of $J$ whereas $E^{r_k+1}(I_k)$ is totally contained in $J$. By definition $E_J(I_k) = E^{r_k+1}(I_k)$. The number $r_k$ is called the return time of $I_k$ to $J$. We remark that the minimality of $E$ also implies that the interval $[a, b)$ is given by the union

$$[a, b) = \bigcup_{k=1}^n \bigcup_{j=1}^{r_k} E^j(I_k).$$
Rauzy’s map. Take $(\pi, \lambda) \in G_n \times \Delta^{n-1}$ and let $E$ be the $(\pi, \lambda)$-interval exchange. Consider $\nu = \nu(\pi, \lambda)$ defined as the minimum between $\lambda_n$ and $\lambda_{n-1}(n)$ provided that these numbers are different. If $E_J$ is the induced map of $E$ onto the interval $J := [0, 1 - \nu)$, $\nu > 0$, it is proved in [15, 16] that $E_J$ is an iet of exactly $n$ intervals associated to a new irreducible permutation $\pi' \in G_n$ and some vector in $\mathbb{R}^n_+$. Then, by normalizing $E_J$, we obtain a pair $(\pi', \lambda') \in G_n \times \Delta^{n-1}$.

Rauzy’s Renormalization map is the association $(\pi, \lambda) \xrightarrow{R} (\pi', \lambda')$. We remark that such association is not defined when $\lambda_n = \lambda_{n-1}(n)$. As a consequence of this, when all iterates $R^n$ of the Rauzy map $R$ are defined in an iet $E_\lambda = (\pi, \lambda)$, then the orbits of any pair of discontinuity points of $E_\lambda$ are disjoint and so, by a Keane’s result [10], $E_\lambda$ is minimal.

It is proved in [15] that $G_n$ is divided into several subsets called Rauzy Classes which are invariant by the process of induction just defined. Let us denote by $C$ one of the Rauzy classes of $G_n$. Then if $\pi \in C$ and $R(\pi, \lambda) = (\pi', \lambda')$, then $\pi' \in C$. Set

$$\Delta_C^{n-1} := \{ (\lambda_1, \lambda_2, \ldots, \lambda_n) \in \Delta^{n-1} : \lambda_n \neq \lambda_{n-1}(n), \pi \in C \}.$$  

Then the transformation $R(\pi, \lambda) = (\pi', \lambda')$ is well defined in $C \times \Delta_C^{n-1}$. In $C \times \Delta^{n-1}$ there is a natural measure $m$ which is the product of the counting measure in $C$ and the $(n-1)$-dimensional Lebesgue measure in $\Delta^{n-1}$. As the set $\Delta_C^{n-1}$ has total measure in $\Delta^{n-1}$ (regarding the $(n-1)$-dimensional Lebesgue measure), the map $R$ is defined $m$-almost everywhere in $C \times \Delta^{n-1}$ and by abuse of language it is usually written

$$R : C \times \Delta^{n-1} \to C \times \Delta^{n-1}.$$  

Rauzy’s transformation plays a central role in the ergodic theory of iets due to the following result [18, 13].

Theorem 5. Rauzy’s operator is ergodic for a measure which is absolutely continuous with respect to the probability measure $m$ defined above.

Another related result proved in [18, 13] is

Theorem 6. For a fixed permutation $\pi \in C$ and for almost every vector $\lambda \in \Delta^{n-1}$, the $R$-orbit of $E_\lambda$ is dense in $C \times \Delta^{n-1}$.

4. Proof of Theorem 1

First of all, let us show a relation between the process of renormalization and the key property in Theorem 4. Let $E : [0, 1) \to [0, 1)$ be a minimal interval exchange and let $E_I$ be the induced map of $E$ onto $I = [a, b) \subset [0, 1)$. Suppose that $L \subset I$ is an interval of continuity of $E_I$ and that, for some $x \in L$, $\{E_I^{-1}(x), E_I(x)\} \subset L$. If $r$ is the return time of $L$ to $I$ and $B := \omega_0 \omega_1 \ldots \omega_r$, $\omega_j \in \{1, 2, \ldots, n\}$, is the itinerary of $x$ until it returns to $L$ (i.e., $E_I^j(x)$ is in the $\omega_j$-interval of continuity of $E$ for each $0 \leq j \leq r$), then the itinerary of every point in $L$, of length $r$, is given by the same word $B$. Therefore as $E_I(x) \in L$ and $E_I^{-1}(x) \in L$, the itinerary of $x$ associated to $[-r, 2r]$ will be given by the word

$$B \omega_0 \omega_1 \ldots \omega_r B \omega_0 \omega_1 \ldots \omega_r B \omega_0 \omega_1 \ldots \omega_r.$$  

One such point will be called a candidate point in the interval $[a, b)$ for the length $r$.  

License or copyright restrictions may apply to redistribution; see http://www.ams.org/journal-terms-of-use
Observe that if $E^{-1}_1(x), x, E_1(x), \text{ and } E^2_1(x)$ belong to $L$, then the itinerary of each of the points $y = E^k(x), 0 \leq k \leq r$, associated to $[-r, 2r]$ is of the form $WWW$ where $W$ is the word

\[\ldots nk_{k+1} \ldots nk_{k-1}\]

this is, $y$ is also a candidate point for the length $r$. Therefore we have

**Lemma 2.** Under the assumption right above, assume that

\[x \in E^{-2}_1(L) \cap E^{-1}_1(L) \cap L \cap E_1(L).\]

Then $x, E(x), E^2(x), \ldots, E^r(x)$ are all candidate points for the length $r$.

Note that if there is a nested sequence of intervals shrinking to a point $x$,

\[\left[ a_1, b_1 \right) \supset \left[ a_2, b_2 \right) \supset \ldots \supset \left[ a_k, b_k \right) \supset \ldots,\]

such that $x$ is a candidate point for each $[a_k, b_k)$ for the length $r_k$, then necessarily $r_k \to \infty$ as $k \to \infty$, and the itinerary of $x$ associated to its whole orbit is given by a sequence that satisfies the hypotheses of Theorem 4.

**The periodic iet $P$.** Let us consider the following family of periodic iets. Let $n \in \mathbb{N}$ be a natural number and let $\pi \in G_n$ be an arbitrary irreducible permutation. Consider the vector

\[\lambda^* := \left( \frac{1}{n}, \frac{1}{n}, \ldots, \frac{1}{n} \right) \in \mathbb{R}^n;\]

then the intervals of continuity of the iet $P := (\pi, \lambda^*)$ are of the form

\[I_k^* := \left[ \frac{k}{n}, \frac{k+1}{n} \right), 0 \leq k \leq n-1,\]

and $P$ sends any interval $I_k^*$ onto the interval $I_{P(k)}^*$. In this way, for each $k \in \{1, 2, \ldots, n\}$, there is a positive integer $l_k$ such that

\[P^{l_k+1}(I_k^*) = I_k^*;\]

in particular, $P$ is a periodic iet; that is, for some $N \in \mathbb{N}$, $P^N$ is the identity map. We may suppose that $l_k$ is the smallest positive integer with this property. Every $x \in I_k^*$ is a periodic point of period $l_k$ and therefore a candidate point for the length $l_k$. The induced map of $P$ in $I_k^*$ is the identity. If $E$ is an iet very close to $P$ and $I$ is an interval of continuity of $E$, the induced map $E_I$ in $I$ is very “close” to the identity”: there is an interval of continuity of $E_I$ whose length is very close to that of $I$. By shortening this interval a little we obtain an interval $L$ such that the length of $E^{-1}_1(L) \cap E^{-1}_1(L) \cap L \cap E_1(L)$ is still close to the length of $I$. Lemma 2 guarantees that all the points in this intersection are candidate points for the length $l_k$.

By the comment that followed Theorem 4, the proof of Theorem 1 is a consequence of the following proposition.

**Proposition 1.** Fix an irreducible permutation $\pi \in G_n$. Then for almost all $\lambda \in \Delta^{n-1}$ and for almost all $x \in [0, 1)$, the coding $\omega_\lambda(x)$ satisfies the hypotheses of Theorem 4.

**Proof.** Consider the periodic iet $P = (\pi, \lambda^*)$, where $\lambda^* := \left( \frac{1}{n}, \frac{1}{n}, \ldots, \frac{1}{n} \right)$, and let $l_k, 1 \leq k \leq n-1$, be the smallest positive integer such that $P^{l_k}(\left[ \frac{k}{n}, \frac{k+1}{n} \right)) = \left[ \frac{k}{n}, \frac{k+1}{n} \right)$.

For any small number $\delta > 0$, let $\vartheta(\delta)$ be the set of iets $E = (\pi, \lambda)$ with

\[\max\{|\lambda_i - \frac{1}{n}| : 1 \leq i \leq n\} < \delta.\]
Fix $0 < \epsilon < 1$. Given a natural number $m$, there exists $\delta_m > 0$ such that if $E \in \vartheta(\delta_m)$ and $k \in \{1, 2, \ldots, n\}$, then the $k^{th}$-interval of continuity of $E$, denoted by $I_k$, contains an interval $L$ such that the sets $E_{I_k}^{-2}(L)$, $E_{I_k}^{-1}(L)$, and $E(L)$ are subintervals of $I_k$ and the interval

$$M_k := E_{I_k}^{-2}(L) \cap E_{I_k}^{-1}(L) \cap L \cap E_{I_k}(L)$$

satisfies

$$\frac{|M_k|}{|I_k|} \geq 1 - \frac{\epsilon}{2^m},$$

where $|A|$ denotes the Lebesgue measure of $A$.

Recall that the Rauzy orbit of $E_\lambda := (\pi, \lambda)$ is dense in $C \times \Delta^{n-1}$ for almost all $\lambda \in \Delta^{n-1}$ (Theorem 6). Take an iet $E$ whose Rauzy orbit is dense. Then there are

- a1) a nested sequence of half-open intervals $J_1 \supseteq J_2 \supseteq \cdots \supseteq J_m \supseteq \cdots$
- a2) a sequence of linear bijections $H_m : J_m \to [0, 1)$, and
- a3) an increasing sequence $(N_m)_{m \geq 1}$ of natural numbers such that $E_m := R^{N_m}(E) = H_m \circ E_{J_m} \circ H_m^{-1}$ belongs to $\vartheta(\delta_m)$, where $E_{J_m}$ is the map induced by $E$ onto $J_m$.

Fix $m \in \mathbb{N}$ and, for each $k$ in $\{1, 2, \ldots, n\}$, let $I_k$ be the $k^{th}$ interval of continuity of $E_m$ and let $M_k \subset I_k$ be a set that satisfies (4). Let $r_k$ be the return time, with respect to $E$, of the interval $I_k$ to $J_m$. By Lemma 2, all the iterates $M_k, E(M_k), \ldots, E^{r_k}(M_k)$ are made of candidate points for the length $r_k$. As $E$ preserves the Lebesgue measure, each of these sets has Lebesgue measure greater than $1 - \epsilon \cdot 2^{-m}$ times the measure of $I_k$. This implies that the set of candidate points, for the length $r_k$, in the union

$$\bigcup_{j=1}^{r_k} E^j(I_k)$$

is greater than $1 - \epsilon \cdot 2^{-m}$ times the Lebesgue measure of this union.

Let $C_m$ be the set of candidate points in $[0, 1)$ for lengths $r \leq r_m := \max\{r_1, \ldots, r_n\}$.

Using the fact that

$$[0, 1) = \bigcup_{k=1}^{n} \bigcup_{j=1}^{r_k} E^j(I_k)$$

(see relation (2)), we conclude that $|C_m| \geq 1 - \frac{\epsilon}{2^m}$.

Now it follows easily that the Lebesgue measure of the intersection

$$C_e := \bigcap_{m \geq 1} C_m$$

is greater than $1 - \epsilon \sum_{m \geq 1} 2^{-m} = 1 - \epsilon$. Observe that $(r_m)$ is a strictly increasing sequence and that, for all $m = 1, 2, \ldots$, every point in $C_e$ is a candidate point for the length $r_m$. Therefore all the points in $C_e$ satisfy the condition of Proposition 1. As the number $\epsilon > 0$ is arbitrary, Proposition 1 is proved. □
