

HOW MANY LAPLACE TRANSFORMS OF PROBABILITY MEASURES ARE THERE?

FUCHANG GAO, WENBO V. LI, AND JON A. WELLNER

(Communicated by Richard C. Bradley)

ABSTRACT. A bracketing metric entropy bound for the class of Laplace transforms of probability measures on $[0, \infty)$ is obtained through its connection with the small deviation probability of a smooth Gaussian process. Our results for the particular smooth Gaussian process seem to be of independent interest.

1. INTRODUCTION

Let μ be a finite measure on $[0, \infty)$. The Laplace transform of μ is a function on $(0, \infty)$ defined by

$$(1) \quad f(t) = \int_0^\infty e^{-ty} \mu(dy).$$

It is easy to check that such a function has the property that $(-1)^n f^{(n)}(t) \geq 0$ for all nonnegative integers n and all $t > 0$. A function on $(0, \infty)$ with this property is called a completely monotone function on $(0, \infty)$. A characterization due to Bernstein (cf. Williamson (1956)) says that f is completely monotone on $(0, \infty)$ if and only if there is a nonnegative measure μ (not necessarily finite) on $[0, \infty)$ such that (1) holds. Therefore, due to monotonicity, the class of Laplace transforms of finite measures on $[0, \infty)$ is the same as the class of bounded completely monotone functions on $(0, \infty)$. These functions can be extended to continuous functions on $[0, \infty)$, and we will call them completely monotone on $[0, \infty)$.

Completely monotonic functions have remarkable applications in various fields, such as probability and statistics, physics and potential theory. The main properties of these functions are given in Widder (1941), Chapter IV. For example, the class of completely monotonic functions is closed under sums, products and pointwise convergence. We refer to Alzer and Berg (2002) for a detailed list of references on completely monotonic functions. Closely related to the class of completely monotonic functions are the so-called k -monotone functions, where the nonnegativity of $(-1)^n f^{(n)}$ is required for all integers $n \leq k$. In fact, completely monotonic functions can be viewed as the limiting case of the k -monotone functions as $k \rightarrow \infty$. In this

sense, the present work is a partial extension of Gao (2008) and Gao and Wellner (2009).

Let \mathcal{M}_∞ be the class of completely monotone functions on $[0, \infty)$ that are bounded by 1. Then

$$\mathcal{M}_\infty = \left\{ f : [0, \infty) \rightarrow [0, \infty) \mid f(t) = \int_0^\infty e^{-tx} \mu(dx), \|\mu\| \leq 1 \right\}.$$

It is well known (see e.g. Feller (1971), Theorem 1, page 439) that the subclass of \mathcal{M}_∞ with $f(0) = 1$ corresponds exactly to the Laplace transforms of the class of probability measures μ on $[0, \infty)$. For a random variable with distribution function $F(t) = P(X \leq t)$, define the *survival function* $S(t) = 1 - F(t) = P(X > t)$. Thus the class

$$\mathcal{S}_\infty = \left\{ S : [0, \infty) \rightarrow [0, \infty) \mid S(t) = \int_0^\infty e^{-tx} \mu(dx), \|\mu\| = 1 \right\}$$

is exactly the class of survival functions of all scale mixtures of the standard exponential distribution (with survival function e^{-t}), with corresponding densities

$$p(t) = -S'(t) = \int_0^\infty x e^{-xt} \mu(dx), \quad t \geq 0.$$

It is easily seen that the class \mathcal{P}_∞ of such densities with $p(0) < \infty$ is also a class of completely monotone functions corresponding to probability measures μ on $[0, \infty)$ with finite first moment. These classes have many applications in statistics; see e.g. Jewell (1982) for a brief survey. Jewell (1982) considered nonparametric estimation of a completely monotone density and showed that the nonparametric maximum likelihood estimator (or MLE) for this class is almost surely consistent. The bracketing entropy bounds derived below can be considered as a first step toward global rates of convergence of the MLE.

In probability and statistical applications, one way to understand the complexity of a function class is by way of the metric entropy for the class under certain common distances. Recall that the metric entropy of a function class \mathcal{F} under distance ρ is defined to be $\log N(\varepsilon, \mathcal{F}, \rho)$ where $N(\varepsilon, \mathcal{F}, \rho)$ is the minimum number of open balls of radius ε needed to cover \mathcal{F} . In statistical applications, sometimes bracketing metric entropy is needed. Recall that bracket entropy is defined as $\log N_{[\cdot]}(\varepsilon, \mathcal{F}, \rho)$, where

$$N_{[\cdot]}(\varepsilon, \mathcal{F}, \rho) := \min \left\{ n : \exists \underline{f}_1, \bar{f}_1, \dots, \underline{f}_n, \bar{f}_n \text{ s.t. } \rho(\bar{f}_k, \underline{f}_k) \leq \varepsilon, \mathcal{F} \subset \bigcup_{k=1}^n [\underline{f}_k, \bar{f}_k] \right\}$$

and

$$[\underline{f}_k, \bar{f}_k] = \left\{ g \in \mathcal{F} : \underline{f}_k \leq g \leq \bar{f}_k \right\}.$$

Clearly $N(\varepsilon, \mathcal{F}, \rho) \leq N_{[\cdot]}(\varepsilon, \mathcal{F}, \rho)$, and they are closely related in our setting below.

In this paper, we study the metric entropy of \mathcal{M}_∞ under the $L^p(\nu)$ -norm given by

$$\|f\|_{L^p(\nu)}^p = \int_0^\infty |f(x)|^p \nu(dx), \quad 1 \leq p \leq \infty,$$

where ν is a probability measure on $[0, \infty)$. Our main result is the following.

Theorem 1.1. (i) Let ν be a probability measure on $[0, \infty)$. There exists a constant C depending only on $p \geq 1$ such that for any $0 < \varepsilon < 1/4$,

$$\log N_{[]}(\varepsilon, \mathcal{M}_\infty, \|\cdot\|_{L^p(\nu)}) \leq C \log(\Gamma/\gamma) \cdot |\log \varepsilon|^2,$$

for any $0 < \gamma < \Gamma < \infty$ such that $\nu([\gamma, \Gamma]) \geq 1 - 4^{-p}\varepsilon^p$. In particular, if there exists a constant $K > 1$, such that $\nu([\varepsilon^K, \varepsilon^{-K}]) \geq 1 - 4^{-p}\varepsilon^p$, then

$$\log N_{[]}(\varepsilon, \mathcal{M}_\infty, \|\cdot\|_{L^p(\nu)}) \leq CK |\log \varepsilon|^3.$$

(ii) If ν is Lebesgue measure on $[0, 1]$, then

$$\log N_{[]}(\varepsilon, \mathcal{M}_\infty, \|\cdot\|_{L^2(\nu)}) \asymp \log N(\varepsilon, \mathcal{M}_\infty, \|\cdot\|_{L^2(\nu)}) \asymp |\log \varepsilon|^3,$$

where $A \asymp B$ means that there exist universal constants $C_1, C_2 > 0$ such that $C_1 A \leq B \leq C_2 B$.

As an equivalent result for part (ii) of the above theorem, we have the following important small deviation probability estimates for an associated smooth Gaussian process. In particular, it may be of interest to find a probabilistic proof for the lower bound directly.

Theorem 1.2. Let $Y(t), t > 0$, be a Gaussian process with covariance $\mathbb{E}Y(t)Y(s) = (1 - e^{-t-s})/(t + s)$. Then for $0 < \varepsilon < 1$,

$$\log \mathbb{P} \left(\sup_{t>0} |Y(t)| < \varepsilon \right) \asymp -|\log \varepsilon|^3.$$

The rest of the paper is organized as follows. In Section 2, we provide the upper bound estimate in the main result by explicit construction. In Section 3, we summarize various connections between entropy numbers of a set (and its convex hull) and small ball probabilities for the associated Gaussian process. Some of our observations in a general setting are stated explicitly for the first time. Finally we identify the particular Gaussian process suitable for our entropy estimates. Then in Section 4, we obtain the required upper bound small ball probability estimate (which implies the lower bound entropy estimate as discussed in section 3) by a simple determinant estimate. This method of small ball estimates is made explicit here for the first time and can be used in many more problems. The technical determinant estimates are also of independent interest.

2. UPPER BOUND ESTIMATE

In this section, we provide an upper bound for $N_{[]}(\varepsilon, \mathcal{M}_\infty, \|\cdot\|_{L^p(\nu)})$, where ν is a probability measure on $[0, \infty)$ and $1 \leq p \leq \infty$. Before we start, we note that \mathcal{M}_∞ is the convex hull of $\mathcal{K} := \{K(t, \cdot) : t \in [0, \infty)\}$, where for each $t \in [0, \infty)$, $K(t, \cdot)$ is a function on $[0, \infty)$ defined by $K(t, x) = e^{-tx}$. There are some general results on metric entropy of convex hulls $\text{conv}(T)$ using the metric entropy of T . (Cf. Dudley (1987), Ball and Pajor (1990), van der Vaart and Wellner (1996), Carl (1997), Carl et al. (1999), Li and Linde (2000), Gao (2004), etc.) For example, Carl et al. (1999) proved that if $N(\varepsilon, T, \|\cdot\|) = O(\varepsilon^{-\alpha})$, $\alpha > 0$, then

$$\log N(\varepsilon, \text{conv}(T), \|\cdot\|) = O(\varepsilon^{-2\alpha/(2+\alpha)}),$$

where $\|\cdot\|$ is any Banach space norm. Although these results are best possible for the general case, when applied to specific problems they could be far from being sharp. This is especially the case when the metric entropy of T grows at a polynomial rate. For example, in our case, because the functions e^{-kx} , $k = 1, 2, \dots, n$, have mutual

$L^2[0, 1]$ -distance at least $\frac{1}{2}n^{-3/2}$, we immediately have $N(\varepsilon, \mathcal{K}, \|\cdot\|_{L^2[0,1]}) \geq C\varepsilon^{-2/3}$. Thus, in the case $p = 2$ and with ν taken to be Lebesgue measure on $[0, 1]$, the best upper bound we can hope to obtain using the general convex hull result quoted above is

$$\log N(\varepsilon, \mathcal{M}_\infty, \|\cdot\|_{L^2(\nu)}) \leq C_2\varepsilon^{-1/2},$$

which is much larger (at least in the dependence on ε) than the upper bound

$$\log N(\varepsilon, \mathcal{M}_\infty, \|\cdot\|_{L^2(\nu)}) \leq C|\log \varepsilon|^3,$$

which we will obtain later in the section.

We will obtain our upper bound estimate by an explicit construction of ε -brackets under $L^p(\nu)$ -distance.

For each $0 < \varepsilon < 1/4$, we choose $\gamma > 0$ and $\Gamma = 2^m\gamma$, where m is a positive integer such that $\nu([\gamma, \Gamma]) \geq 1 - 4^{-p}\varepsilon^p$. We use the notation $\mathbb{I}(a \leq t < b)$ to denote the indicator function of the interval $[a, b)$. Now for each $f \in \mathcal{M}_\infty$, we first write in block form

$$f(t) = \mathbb{I}(0 \leq t < \gamma)f(t) + \mathbb{I}(t \geq \Gamma)f(t) + \sum_{i=1}^m \mathbb{I}(2^{i-1}\gamma \leq t < 2^i\gamma)f(t).$$

Then for each block $2^{i-1}\gamma \leq t < 2^i\gamma$, we separate the integration limits at the level $2^{2-i}|\log \varepsilon|/\gamma$ and use the first N terms of Taylor's series expansion of e^{-u} with error terms associated with $\xi = \xi_{u,N}$, $0 \leq \xi \leq 1$, to rewrite

$$f(t) = \mathbb{I}(0 \leq t < \gamma)f(t) + \mathbb{I}(t \geq \Gamma)f(t) + \sum_{i=1}^m (p_i(t) + q_i(t) + r_i(t)),$$

where

$$\begin{aligned} p_i(t) &=: \mathbb{I}(2^{i-1}\gamma \leq t < 2^i\gamma) \sum_{n=0}^N \frac{(-1)^n t^n}{n!} \int_0^{2^{2-i}|\log \varepsilon|/\gamma} x^n \mu(dx), \\ q_i(t) &=: \mathbb{I}(2^{i-1}\gamma \leq t < 2^i\gamma) \int_0^{2^{2-i}|\log \varepsilon|/\gamma} \frac{(-\xi tx)^{N+1}}{(N+1)!} \mu(dx), \\ r_i(t) &=: \mathbb{I}(2^{i-1}\gamma \leq t < 2^i\gamma) \int_{2^{2-i}|\log \varepsilon|/\gamma}^\infty e^{-tx} \mu(dx). \end{aligned}$$

We choose the integer N so that

$$(2) \quad 4e^2|\log \varepsilon| - 1 \leq N < 4e^2|\log \varepsilon|.$$

Then, by using the inequality $k! \geq (k/e)^k$ and the fact that $0 < \xi < 1$, we have within the block $2^{i-1}\gamma \leq t < 2^i\gamma$,

$$\begin{aligned} |q_i(t)| &\leq \int_0^{2^{2-i}|\log \varepsilon|/\gamma} \frac{(tx)^{N+1}}{(N+1)!} \mu(dx) \\ &\leq \frac{|4 \log \varepsilon|^{N+1}}{(N+1)!} \leq \left(\frac{4e|\log \varepsilon|}{N+1}\right)^{N+1} \leq e^{-(N+1)} \leq \varepsilon^{4e^2}, \end{aligned}$$

where we used $tx \leq 2^i\gamma \cdot 2^{2-i}|\log \varepsilon|/\gamma = 4|\log \varepsilon|$ in the second inequality above. This implies, due to disjoint supports of $q_i(t)$,

$$(3) \quad \left| \sum_{i=1}^m q_i(t) \right| \leq \varepsilon^{4e^2}.$$

Next, we notice that for $t \geq 2^{i-1}\gamma$ and $x \geq 2^{2-i}\gamma^{-1}|\log \varepsilon|$, $e^{-tx} \leq \varepsilon^2$. Thus

$$(4) \quad \left| \sum_{i=1}^m r_i(t) \right| \leq \sum_{i=1}^m \mathbb{I}(2^{i-1}\gamma \leq t < 2^i\gamma) \int_{2^{2-i}\gamma^{-1}|\log \varepsilon|}^{\infty} \varepsilon^2 \mu(dx) \leq \varepsilon^2.$$

Finally, because $|f| \leq 1$ and $\nu([0, \gamma)) + \nu([\Gamma, \infty)) \leq 4^{-p}\varepsilon^p$, we have

$$\|\mathbb{I}_{0 \leq t < \gamma} f(t) + \mathbb{I}_{t \geq \Gamma} f(t)\|_{L^p(\nu)} \leq \varepsilon/4.$$

Together with (3) and (4), we see that the set

$$\mathcal{R} =: \left\{ \sum_{i=1}^m q_i(t) + \sum_{i=1}^m r_i(t) + \mathbb{I}(t < \gamma)f(t) + \mathbb{I}(t \geq \Gamma)f(t) : f \in \mathcal{M}_{\infty} \right\}$$

has diameter in $L^p(\nu)$ -distance at most $\varepsilon^2 + \varepsilon^{4e^2} + \varepsilon/4 < \varepsilon/2$.

Therefore, if we denote $\mathcal{P}_i = \{p_i(t) : f \in \mathcal{M}_{\infty}\}$, then the expansion of f above implies that $\mathcal{M}_{\infty} \subset \sum_{i=1}^m \mathcal{P}_i + \mathcal{R}$, and consequently, we have

$$N_{[]}(\varepsilon, \mathcal{M}_{\infty}, \|\cdot\|_{L^p(\nu)}) \leq N_{[]} \left(\varepsilon/2, \sum_{i=1}^m \mathcal{P}_i, \|\cdot\|_{L^p(\nu)} \right).$$

For any $1 \leq i \leq m$ and any $p_i \in \mathcal{P}_i$, we can write

$$(5) \quad p_i(t) = \mathbb{I}(2^{i-1}\gamma \leq t < 2^i\gamma) \sum_{n=0}^{N_i} (-1)^n a_{ni} (2^{-i}\gamma^{-1}t)^n,$$

where $0 \leq a_{ni} \leq |4 \log \varepsilon|^n/n!$. Now we can construct

$$\begin{aligned} \bar{p}_i &= \mathbb{I}(2^{i-1}\gamma \leq t < 2^i\gamma) \sum_{n=0}^N (-1)^n b_{ni} (2^{-i}\gamma^{-1}t)^n, \\ \underline{p}_i &= \mathbb{I}(2^{i-1}\gamma \leq t < 2^i\gamma) \sum_{n=0}^N (-1)^n c_{ni} (2^{-i}\gamma^{-1}t)^n, \end{aligned}$$

where

$$b_{ni} = \begin{cases} \frac{\varepsilon}{2^{n+2}} \lceil \frac{2^{n+2} a_{ni}}{\varepsilon} \rceil & \text{if } n \text{ is even,} \\ \frac{\varepsilon}{2^{n+2}} \lfloor \frac{2^{n+2} a_{ni}}{\varepsilon} \rfloor & \text{if } n \text{ is odd,} \end{cases} \quad c_{ni} = \begin{cases} \frac{\varepsilon}{2^{n+2}} \lfloor \frac{2^{n+2} a_{ni}}{\varepsilon} \rfloor & \text{if } n \text{ is even,} \\ \frac{\varepsilon}{2^{n+2}} \lceil \frac{2^{n+2} a_{ni}}{\varepsilon} \rceil & \text{if } n \text{ is odd.} \end{cases}$$

Clearly, $\underline{p}_i(t) \leq p_i(t) \leq \bar{p}_i(t)$, and

$$\begin{aligned} |\bar{p}_i - \underline{p}_i| &\leq \mathbb{I}(2^{i-1}\gamma \leq t < 2^i\gamma) \sum_{n=0}^N |c_{ni} - b_{ni}| (2^{-i}\gamma^{-1}t)^n \\ &\leq \mathbb{I}(2^{i-1}\gamma \leq t < 2^i\gamma) \sum_{n=0}^N \frac{\varepsilon}{2^{n+2}} (2^{-i}\gamma^{-1}t)^n \\ &\leq \frac{\varepsilon}{2} \mathbb{I}(2^{i-1}\gamma \leq t < 2^i\gamma). \end{aligned}$$

Hence

$$\sum_{i=1}^m \underline{p}_i \leq \sum_{i=1}^m p_i \leq \sum_{i=1}^m \bar{p}_i \leq \sum_{i=1}^m \underline{p}_i + \varepsilon/2.$$

That is, the sets

$$\underline{\mathcal{P}} =: \left\{ \sum_{i=1}^m \underline{p}_i : p_i \in \mathcal{P}_i, 1 \leq i \leq m \right\} \quad \text{and} \quad \overline{\mathcal{P}} =: \left\{ \sum_{i=1}^m \overline{p}_i : p_i \in \mathcal{P}_i, 1 \leq i \leq m \right\}$$

form $\varepsilon/2$ brackets of $\sum_{i=1}^m \mathcal{P}_i$ in the L^∞ -norm, and thus in the $L^p(\nu)$ -norm for all $1 \leq p < \infty$.

Now we count the number of different realizations of $\overline{\mathcal{P}}$ and $\underline{\mathcal{P}}$. Note that, due to the uniform bound on a_{ni} in (5), there are no more than

$$\frac{2^{n+1}}{\varepsilon} \cdot \frac{|4 \log \varepsilon|^n}{n!} + 1$$

realizations for b_{ni} . So, the number of realizations of \overline{p}_i is bounded by

$$\prod_{n=0}^N \left(\frac{2^{n+1}}{\varepsilon} \cdot \frac{|4 \log \varepsilon|^n}{n!} + 1 \right).$$

Because $n! > (n/e)^n$, for all $1 \leq n \leq N$, we have

$$\frac{2^{n+1}}{\varepsilon} \cdot \frac{|4 \log \varepsilon|^n}{n!} + 1 \leq \frac{3}{\varepsilon} \left(\frac{8e |\log \varepsilon|}{n} \right)^n.$$

Thus, the number of realizations of \overline{p}_i is bounded by

$$\begin{aligned} & \left(\frac{3}{\varepsilon} \right)^{N+1} \cdot \exp \left(\sum_{n=1}^N (n \log |8e \log \varepsilon| - n \log n) \right) \\ & \leq \left(\frac{3}{\varepsilon} \right)^{N+1} \cdot \exp \left(\frac{N(N+1)}{2} \log |8e \log \varepsilon| - \int_1^N x \log x dx \right) \\ & \leq \left(\frac{3}{\varepsilon} \right)^{N+1} \cdot \exp \left(\frac{N(N+1)}{2} \log |8e \log \varepsilon| - \frac{N^2}{2} \log N + \frac{N^2}{4} \right) \\ & \leq \exp(C |\log \varepsilon|^2) \end{aligned}$$

for some absolute constant C , where in the last inequality we used the bounds on N given in (2).

Hence the total number of realizations of $\overline{\mathcal{P}}$ is bounded by $\exp(Cm |\log \varepsilon|^2)$. A similar estimate holds for the total number of realizations of $\underline{\mathcal{P}}$, and we finally obtain

$$\log N_{[\cdot]}(\varepsilon, \mathcal{M}_\infty, \|\cdot\|_{L^p(\nu)}) \leq C' m |\log \varepsilon|^2$$

for some different constant C' . This finishes the proof since $m = \log_2(\Gamma/\gamma)$.

3. ENTROPY OF CONVEX HULLS

A lower bound estimate of metric entropy is typically difficult, because it often involves a construction of a well-separated set of maximal cardinality. Thus we introduce some soft analytic arguments to avoid this difficulty and change the problem into a familiar one in this section. The hard estimates are given in the next section.

First note that \mathcal{M}_∞ is just the convex hull of the functions $k_s(\cdot)$, $0 < s < \infty$, where $k_s(t) = e^{-ts}$. We recall a general method to bound the entropy of convex

hulls that was introduced in Gao (2004). Let T be a set in \mathbb{R}^n or in a Hilbert space. The convex hull of T can be expressed as

$$\text{conv}(T) = \left\{ \sum_{n=1}^{\infty} a_n t_n : t_n \in T, a_n \geq 0, n \in \mathbb{N}, \sum_{n=1}^{\infty} a_n = 1 \right\},$$

while the absolute convex hull of T is defined by

$$\text{abconv}(T) = \left\{ \sum_{n=1}^{\infty} a_n t_n : t_n \in T, n \in \mathbb{N}, \sum_{n=1}^{\infty} |a_n| \leq 1 \right\}.$$

Clearly, by using probability measures and signed measures, we can express

$$\begin{aligned} \text{conv}(T) &= \left\{ \int_T t \mu(dt) : \mu \text{ is a probability measure on } T \right\}; \\ \text{abconv}(T) &= \left\{ \int_T t \mu(dt) : \mu \text{ is a signed measure on } T, \|\mu\|_{TV} \leq 1 \right\}. \end{aligned}$$

The following is clear:

$$\text{conv}(T) \subset \text{abconv}(T) \subset \text{conv}(T) - \text{conv}(T).$$

Therefore, for any norm $\|\cdot\|$,

$$N(\varepsilon, \text{conv}(T), \|\cdot\|) \leq N(\varepsilon, \text{abconv}(T), \|\cdot\|) \leq [N(\varepsilon/2, \text{conv}(T), \|\cdot\|)]^2.$$

In particular, at the logarithmic level, the two entropy numbers are comparable, modulo constant factors on ε . The benefit of using the absolute convex hull is that it is symmetric and can be viewed as the unit ball of a Banach space, which allows us to use the following duality lemma of metric entropy: there exist constants $c_1, c_2, K_1, K_2 > 0$ such that for all $\varepsilon > 0$,

$$\begin{aligned} K_1 \log N(c_1 \varepsilon, \text{abconv}(T), \|\cdot\|_2) &\leq \log N(\varepsilon, B, \|\cdot\|_T) \\ &\leq K_2 \log N(c_2 \varepsilon, \text{abconv}(T), \|\cdot\|_2), \end{aligned}$$

where B is the unit ball of the dual norm of $\|\cdot\|$, and $\|\cdot\|_T$ is the norm induced by T , that is,

$$\|x\|_T := \sup_{t \in T} |\langle t, x \rangle| = \sup_{t \in \text{abconv}(T)} |\langle t, x \rangle|.$$

Strictly speaking, the duality lemma remains a conjecture in the general case. However, when the norm $\|\cdot\|$ is a Hilbert space norm, this has been proved; see Tomczak-Jaegermann (1987), Bourgain et al. (1989), and Artstein et al. (2004).

A striking relation discovered by Kuelbs and Li (1993) says that the entropy number $\log N(\varepsilon, B, \|\cdot\|_T)$ is determined by the Gaussian measure of the set

$$D_\varepsilon =: \{x \in H : \|x\|_T \leq \varepsilon\}$$

under some very weak regularity assumptions. For details, see Kuelbs and Li (1993), Li and Linde (1999), and also Corollary 2.2 of Aurzada et al. (2009). Using this relation, we can now summarize the connection between the metric entropy of convex hulls and the Gaussian measure of D_ε as follows:

Proposition 3.1. *Let T be a precompact set in a Hilbert space. For $\alpha > 0$ and $\beta \in \mathbb{R}$, there exists a constant $C_1 > 0$ such that for all $0 < \varepsilon < 1$,*

$$\log \mathbb{P}(D_\varepsilon) \leq -C_1 \varepsilon^{-\alpha} |\log \varepsilon|^\beta$$

if and only if there exists a constant $C_2 > 0$ such that for all $0 < \varepsilon < 1$,

$$\log N(\varepsilon, \text{conv}(T), \|\cdot\|) \geq C_2 \varepsilon^{-\frac{2\alpha}{2+\alpha}} |\log \varepsilon|^{\frac{2\beta}{2+\alpha}};$$

and for $\beta > 0$ and $\gamma \in \mathbb{R}$, there exists a constant $C_3 > 0$ such that for all $0 < \varepsilon < 1$,

$$\log \mathbb{P}(D_\varepsilon) \leq -C_3 |\log \varepsilon|^\beta (\log |\log \varepsilon|)^\gamma$$

if and only if there exists a constant $C_4 > 0$ such that for all $0 < \varepsilon < 1$,

$$\log N(\varepsilon, \text{conv}(T), \|\cdot\|_2) \geq C_4 |\log \varepsilon|^\beta (\log |\log \varepsilon|)^\gamma.$$

Furthermore, the results also hold if the directions of the inequalities are switched.

The result of this proposition can be implicitly seen in Gao (2004), where an explanation of the relation between $N(\varepsilon, B, \|\cdot\|_T)$ and the Gaussian measure of D_ε is also given.

Perhaps the most useful case of Proposition 3.1 is when T is a set of functions: $K(t, \cdot)$, $t \in T$, where for each fixed $t \in T$, $K(t, \cdot)$ is a function in $L^2(\Omega)$, and where Ω is a bounded set in \mathbb{R}^d , $d \geq 1$. For this special case, we have

Corollary 3.2. *Let $X(t) = \int_\Omega K(t, x) dB(x)$, $t \in T$, where $K(t, \cdot)$ are square-integrable functions on a bounded set Ω in \mathbb{R}^d , $d \geq 1$, and $B(x)$ is the d -dimensional Brownian sheet on Ω . If \mathcal{F} is the convex hull of the functions $K(t, \cdot)$, $t \in T$, then*

$$\log \mathbb{P}\left(\sup_{t \in T} |X(t)| < \varepsilon\right) \asymp -\varepsilon^{-\alpha} |\log \varepsilon|^\beta$$

for $\alpha > 0$ and $\beta \in \mathbb{R}$ if and only if

$$\log N(\varepsilon, \mathcal{F}, \|\cdot\|) \asymp \varepsilon^{-\frac{2\alpha}{2+\alpha}} |\log \varepsilon|^{\frac{2\beta}{2+\alpha}};$$

and for $\beta > 0$ and $\gamma \in \mathbb{R}$,

$$\log \mathbb{P}\left(\sup_{t \in T} |X(t)| < \varepsilon\right) \asymp -|\log \varepsilon|^\beta (\log |\log \varepsilon|)^\gamma$$

if and only if

$$\log N(\varepsilon, \mathcal{F}, \|\cdot\|_2) \asymp |\log \varepsilon|^\beta (\log |\log \varepsilon|)^\gamma.$$

The authors found this corollary especially useful. For example, it was used in Blei et al. (2007) and Gao (2008) to change a problem of metric entropy into a problem of small deviation probability of a Gaussian process, which is relatively easier. The proof is given in Gao (2008) for the case $\Omega = [0, 1]$, and in Blei et al. (2007) for the case $[0, 1]^d$. For the general case, it can be proved as easily. Indeed, the only thing we need to prove is that $\mathbb{P}(D_\varepsilon)$ can be expressed as the probability of the set $\sup_{t \in T} |X(t)| < \varepsilon$. We outline a proof below. Let ϕ_n be an orthonormal basis of $L^2(\Omega)$. Then

$$X(t) = \int_\Omega K(t, s) dB(s) = \sum_{n=1}^{\infty} \xi_n \int_\Omega K(t, s) \phi_n(s) ds,$$

where ξ_n are i.i.d standard normal random variables. Thus,

$$\begin{aligned} \mathbb{P}(D_\varepsilon) &= \mathbb{P} \left\{ g \in L^2(\Omega) : \left| \int_\Omega f(s)g(s)ds \right| < \varepsilon, f \in \mathcal{F} \right\} \\ &= \mathbb{P} \left\{ g \in L^2(\Omega) : \left| \int_T \int_\Omega K(t,s)g(s)ds\mu(dt) \right| < \varepsilon, \|\mu\|_{TV} \leq 1 \right\} \\ &= \mathbb{P} \left\{ \sum_{n=1}^\infty a_n \phi_n(s) : \sum_{n=1}^\infty a_n^2 < \infty, \left| \sum_{n=1}^\infty a_n \int_T \int_\Omega K(t,s)\phi_n(s)ds\mu(dt) \right| < \varepsilon, \right. \\ &\qquad \qquad \qquad \left. \|\mu\|_{TV} \leq 1 \right\} \\ &= \mathbb{P} \left\{ \sum_{n=1}^\infty a_n \phi_n(s) : \sum_{n=1}^\infty a_n^2 < \infty, \sup_{t \in T} \left| \sum_{n=1}^\infty a_n \int_\Omega K(t,s)\phi_n(s)ds \right| < \varepsilon \right\} \\ &= \mathbb{P} \left(\sup_{t \in T} |X(t)| < \varepsilon \right). \end{aligned}$$

Now returning to our problem to estimate $\log N(\varepsilon, \mathcal{M}_\infty, \|\cdot\|_2)$ in the statement (ii) of Theorem 1.1, where $\|\cdot\|_2$ is the L^2 -norm with respect to Lebesgue measure on $[0, 1]$, we notice that \mathcal{M}_∞ is the convex hull of the functions $K(t, \cdot)$, $t \in [0, \infty)$, on $[0, 1]$, with $K(t, s) = e^{-ts}$. Clearly, for each fixed t , $K(t, \cdot)$ is a square-integrable function on the bounded set $[0, 1]$. Now, for this K , the corresponding $X(t)$ is a Gaussian process on $[0, \infty)$ with covariance

$$(6) \qquad \mathbb{E} X(t)X(s) = \frac{1 - e^{-t-s}}{t + s}, \quad s, t \geq 0.$$

Thus, the problem becomes how to sharply bound the probability

$$\mathbb{P} \left(\sup_{t \in (0,1]} |X(t)| < \varepsilon \right).$$

This will be done in the next section.

4. LOWER BOUND ESTIMATE

Let $X(t)$, $t \geq 0$ be the centered Gaussian process defined in (6). Our goal in this section is to prove that

$$\log \mathbb{P}(\sup_{t \geq 0} |X(t)| < \varepsilon) \leq -C|\log \varepsilon|^3,$$

for some constant $C > 0$.

Note that for any sequence of positive numbers $\{\delta_i\}_{i=1}^n$,

$$\begin{aligned} \mathbb{P} \left(\sup_{t \geq 0} |X(t)| < \varepsilon \right) &\leq \mathbb{P}(\max_{1 \leq i \leq n} |X(\delta_i)| < \varepsilon) \\ (7) \qquad &= (2\pi)^{-n/2}(\det \Sigma)^{-1/2} \int_{\max_{1 \leq i \leq n} |y_i| \leq \varepsilon} \exp(-\langle y, \Sigma^{-1}y \rangle) dy_1 \cdots dy_n \\ &\leq (2\pi)^{-n/2}(\det \Sigma)^{-1/2}(2\varepsilon)^n \\ &\leq \varepsilon^n(\det \Sigma)^{-1/2}, \end{aligned}$$

where we use the covariance matrix

$$\Sigma = (\mathbb{E}X(\delta_i)X(\delta_j))_{1 \leq i, j \leq n} = \left(\frac{1 - e^{-\delta_i - \delta_j}}{\delta_i + \delta_j} \right)_{1 \leq i, j \leq n}.$$

To find a lower bound for $\det(\Sigma)$, we need the following lemma:

Lemma 4.1. *If $0 < b_{ij} < a_{ij}$ for all $1 \leq i, j \leq n$, then*

$$\det(a_{ij} - b_{ij}) \geq \det(a_{ij}) - \sum_{k=1}^n \max_{1 \leq l \leq n} \frac{b_{kl}}{a_{kl}} \cdot \text{per}(a_{ij}),$$

where $\text{per}(a_{ij})$ is the permanent of the matrix (a_{ij}) .

Proof. For notational simplicity, we denote $c_{ij} = a_{ij} - b_{ij}$. Then

$$\begin{aligned} & \det(a_{ij} - b_{ij}) - \det(a_{ij}) \\ &= \sum_{\sigma} (-1)^{\sigma} c_{1,\sigma(1)} c_{2,\sigma(2)} \cdots c_{n,\sigma(n)} - \sum_{\sigma} (-1)^{\sigma} a_{1,\sigma(1)} a_{2,\sigma(2)} \cdots a_{n,\sigma(n)} \\ &= \sum_{\sigma} (-1)^{\sigma} \sum_{k=1}^n [c_{1,\sigma(1)} \cdots c_{k-1,\sigma(k-1)}] (c_{k,\sigma(k)} - a_{k,\sigma(k)}) [a_{k+1,\sigma(k+1)} \cdots a_{n,\sigma(n)}] \\ &\geq - \sum_{\sigma} \sum_{k=1}^n [a_{1,\sigma(1)} \cdots a_{k-1,\sigma(k-1)}] (b_{k,\sigma(k)}) [a_{k+1,\sigma(k+1)} \cdots a_{n,\sigma(n)}] \\ &\geq - \sum_{k=1}^n \max_{1 \leq l \leq n} \frac{b_{kl}}{a_{kl}} \sum_{\sigma} [a_{1,\sigma(1)} \cdots a_{k-1,\sigma(k-1)}] (a_{k,\sigma(k)}) [a_{k+1,\sigma(k+1)} \cdots a_{n,\sigma(n)}] \\ &= - \sum_{k=1}^n \max_{1 \leq l \leq n} \frac{b_{kl}}{a_{kl}} \cdot \text{per}(a_{ij}). \quad \square \end{aligned}$$

In order to use Lemma 4.1 to estimate $\det(\Sigma)$, we set

$$a_{ij} = \frac{1}{\delta_i + \delta_j} \quad \text{and} \quad b_{ij} = e^{-\delta_i - \delta_j} a_{ij}$$

for a specific sequence $\{\delta_i\}_{i=1}^n$ defined by

$$\delta_{mp+q} = 4^{p+m}(m+q), \quad 0 \leq p < m, 1 \leq q \leq m$$

for $n = m^2$.

Clearly, we have

$$(8) \quad 0 < b_{kl}/a_{kl} \leq e^{-2m4^m}, \quad 1 \leq k, l \leq n = m^2.$$

It remains to estimate $\det(a_{ij})$ and $\text{per}(a_{ij})$, which are given in the following lemma.

Lemma 4.2. *For the matrix (a_{ij}) defined above, we have $\text{per}(a_{ij}) \leq 1$ and $\det(a_{ij}) \geq (240e)^{-2m^3}$.*

Proof. It is easy to see that

$$\text{per}(a_{ij}) \leq n! (\max_{i,j} a_{ij})^n \leq \frac{(m^2)!}{(2m4^m)^{m^2}} \leq 1$$

since $a_{ij} \leq (2m4^m)^{-1}$ for $1 \leq i, j \leq n = m^2$.

To estimate $\det(a_{ij})$, we use Cauchy’s determinant identity; see Krattenthaler (1999):

$$\det(a_{ij}) = \det\left(\frac{1}{\delta_i + \delta_j}\right) = \frac{\prod_{1 \leq i < j \leq n} (\delta_j - \delta_i)^2}{\prod_{1 \leq i, j \leq n} (\delta_j + \delta_i)} = \frac{1}{2^n \prod_{i=1}^n \delta_i} \cdot \prod_{1 \leq i < j \leq n} \left(\frac{\delta_j - \delta_i}{\delta_j + \delta_i}\right)^2.$$

To estimate the last product, we partition the set $\{(i, j) : 1 < i < j < n = m^2\}$ into the following three sets and estimate each part separately. For $1 \leq i < j \leq n = m^2$, write $i = mp + q$ and $j = mr + s$ with $1 \leq q, s \leq m$. Denote

$$\begin{aligned} A &= \{(i, j) : i = mp + q, j = mp + s, 0 \leq p \leq m - 1, 1 \leq q < s \leq m\}, \\ B &= \{(i, j) : i = mp + q, j = m(p + 1) + s, 0 \leq p \leq m - 2, 1 \leq q, s \leq m\}, \\ C &= \{(i, j) : i = mp + q, j = mr + s, 0 \leq p \leq m - 3, p + 2 \leq r \leq m - 1, \\ &\qquad\qquad\qquad 1 \leq q, s \leq m\}. \end{aligned}$$

Thus, A, B and C form a partition of $\{(i, j) : 1 \leq i < j \leq n = m^2\}$.

First, for $(i, j) \in A$,

$$\frac{\delta_j - \delta_i}{\delta_j + \delta_i} = \frac{s - q}{2m + s + q} > \frac{s - q}{4m}.$$

Thus

$$\begin{aligned} \prod_{(i,j) \in A} \left(\frac{\delta_j - \delta_i}{\delta_j + \delta_i}\right)^2 &\geq \prod_{p=0}^{m-1} \prod_{1 \leq q < s \leq m} \left(\frac{s - q}{4m}\right)^2 = \prod_{k=1}^{m-1} \prod_{q=1}^{m-k} \left(\frac{k}{4m}\right)^{2m} \\ &\geq \prod_{k=1}^{m-1} \left(\frac{k}{4m}\right)^{2m^2} = \left(\frac{(m-1)!}{(4m)^{m-1}}\right)^{2m^2} \\ &\geq (8e)^{-2m^3}. \end{aligned}$$

Second, for $(i, j) \in B$,

$$\frac{\delta_j - \delta_i}{\delta_j + \delta_i} = \frac{(4m + 4s) - (m + q)}{(4m + 4s) + (m + q)} \geq \frac{1}{5}.$$

Thus we have

$$\prod_{(i,j) \in B} \left(\frac{\delta_j - \delta_i}{\delta_j + \delta_i}\right)^2 \geq \prod_{p=0}^{m-2} \prod_{1 \leq q, s \leq m} 5^{-2} \geq 5^{-2m^3}.$$

Third, for $(i, j) \in C$, we have $r - p \geq 2$, and

$$\left(\frac{\delta_j - \delta_i}{\delta_j + \delta_i}\right) = \frac{4^r(m + s) - 4^p(m + q)}{4^r(m + s) + 4^p(m + q)} = 1 - \frac{2 \cdot 4^p(m + q)}{4^r(m + s) + 4^p(m + q)} > 1 - \frac{1}{4^{r-p-1}}.$$

Thus, since $\prod(1 - x_k) \geq 1 - \sum x_k$ for $0 < x_k < 1$,

$$\begin{aligned} \prod_{(i,j) \in C} \left(\frac{\delta_j - \delta_i}{\delta_j + \delta_i} \right)^2 &\geq \prod_{p=0}^{m-3} \prod_{r=p+2}^{m-1} \prod_{1 \leq q, s \leq m} \left(1 - \frac{1}{4^{r-p-1}} \right)^2 \\ &\geq \prod_{k=1}^{m-2} (1 - 4^{-k})^{2m^3} \\ &\geq \left(1 - \sum_{k=1}^{m-2} 4^{-k} \right)^{2m^3} \\ &\geq (2/3)^{2m^3}. \end{aligned}$$

Therefore, we have

$$\prod_{1 \leq i < j \leq n} \left(\frac{\delta_j - \delta_i}{\delta_j + \delta_i} \right)^2 = \prod_{(i,j) \in A} \cdot \prod_{(i,j) \in B} \cdot \prod_{(i,j) \in C} \left(\frac{\delta_j - \delta_i}{\delta_j + \delta_i} \right)^2 \geq (60e)^{-2m^3}.$$

On the other hand, it is not difficult to see that

$$\begin{aligned} 2^n \prod_{i=1}^n \delta_i &= 2^{m^2} \prod_{q=1}^m \prod_{p=0}^{m-1} 4^{p+m} (m+q) < 2^{m^2} \cdot 4^{m^2(m-1)/2+m^3} (2m)^{m^2} \\ &= 4^{3m^3/2+m^2/2+m^2 \log_4 m} < 4^{2m^3} \end{aligned}$$

for $m > 1$. Hence,

$$\det(a_{ij}) = \left(2^n \prod_{i=1}^n \delta_i \right)^{-1} \cdot \prod_{1 \leq i < j \leq n} \left(\frac{\delta_j - \delta_i}{\delta_j + \delta_i} \right)^2 \geq (240e)^{-2m^3}. \quad \square$$

Now combining the two lemmas above and using the estimate in (8), we obtain

$$\det(\Sigma) \geq (240e)^{-2m^3} - m^2 \cdot e^{-2m^4} \geq e^{-16m^3}$$

provided that m is large enough. Plugging into (7), we have

$$\mathbb{P} \left(\sup_{t \geq 0} |X(t)| < \varepsilon \right) \leq e^{8m^3} \varepsilon^{m^2}.$$

Minimizing the right-hand side by choosing $m \approx |\log \varepsilon|/12$, we obtain

$$\mathbb{P} \left(\sup_{t \geq 0} |X(t)| < \varepsilon \right) \lesssim \exp \left(-(432)^{-1} |\log \varepsilon|^3 \right).$$

Statement (ii) of Theorem 1.1 follows by applying Corollary 3.2. At the same time, we also finish the proof of Theorem 1.2.

ACKNOWLEDGMENT

We owe thanks to the referee for a number of helpful suggestions.
