THE MOVEMENT OF A SOLID IN AN INCOMPRESSIBLE PERFECT FLUID AS A GEODESIC FLOW

OLIVIER GLASS AND FRANCK SUEUR

(Communicated by Walter Craig)

ABSTRACT. The motion of a rigid body immersed in an incompressible perfect fluid which occupies a three-dimensional bounded domain has recently been studied under its PDE formulation. In particular, classical solutions have been shown to exist locally in time. In this paper, following the celebrated result of Arnold concerning the case of a perfect incompressible fluid alone, we prove that these classical solutions are the geodesics of a Riemannian manifold of infinite dimension, in the sense that they are the critical points of an action, which is the integral over time of the total kinetic energy of the fluid-rigid body system.

1. INTRODUCTION

We consider the motion of a rigid body immersed in an incompressible homogeneous perfect fluid so that the system fluid-rigid body occupies a smooth open and bounded domain $\Omega \subset \mathbb{R}^3$. The solid is supposed to occupy at each instant $t \geq 0$ a smooth closed connected subset $S(t) \subset \Omega$ which is surrounded by a perfect incompressible fluid filling the domain $F(t) := \Omega \setminus S(t)$.

For the point of view of PDEs, this system has recently been studied in [8], [9], [10], [6], [5] which have set a Cauchy theory for classical solutions.

The aim of this note is to provide a rigorous proof that the classical solutions can be equivalently thought of as geodesics of a Riemannian manifold of infinite dimension, in the sense that they are the critical points of an action, which is the integral over time of the total kinetic energy of the fluid-rigid body system. It was pointed out in a famous paper by Arnold [1] that both the Euler equations for a rigid body as well as the Euler equations for a perfect fluid can be derived with this approach. The motion of a rigid body in a frame attached to its center of mass can be considered as a geodesic on the special orthogonal group $SO(3)$. On the other hand, the motion of a perfect fluid filling a container $\Omega$ (without any immersed rigid body in it) can be considered as a geodesic equation on the space $\text{Sdiff}^+ (\Omega)$ of the volume and orientation preserving diffeomorphisms of $\Omega$.

It is hence natural to try to extend this analysis to a system of interaction of a perfect fluid and a rigid body. Particular cases when the fluid is irrotational or when the vorticity of the fluid is given by a finite number of point vortices so that the dynamics is finite-dimensional have been studied in detail in [11, 12]; see also the references therein. The goal of this paper is to observe that one can see the motion of a rigid body in a fluid governed by the incompressible Euler equations, as a geodesic flow, in the presence of a regular distributed vorticity as well.

The structure of this paper is as follows. In Subsection 1.1 we first recall the PDE formulation of the system. Then in Subsection 1.2 we describe the infinite-dimensional manifold and the action used in the geometric formulation of the problem. In Subsection 1.3 we state the main result of the paper, that is, the equivalence of the two points of view. Section 2 contains the proofs of the various statements.

1.1. PDE formulation. The dynamics of this system can be described thanks to the following PDEs:

\[
\begin{align*}
\frac{\partial u}{\partial t} + (u \cdot \nabla)u + \nabla p &= 0 \quad \text{for } x \in \mathcal{F}(t), \\
\text{div } u &= 0 \quad \text{for } x \in \mathcal{F}(t), \\
mx''_B(t) &= \int_{\partial \mathcal{S}(t)} pn \, d\Gamma, \\
(Jr)'(t) &= \int_{\partial \mathcal{S}(t)} (x - x_B) \times pn \, d\Gamma, \\
u \cdot n &= 0, \quad \text{for } x \in \partial \Omega, \\
u \cdot n &= v \cdot n, \quad \text{for } x \in \partial \mathcal{S}(t), \\
u|_{t=0} &= u_0, \\
\ell(0) &= \ell_0, \\
r(0) &= r_0, \\
x_B(0) &= x_0.
\end{align*}
\]

Equations (1.1) and (1.2) are the incompressible Euler equations. The vector field \(u\) is the fluid velocity and the scalar field \(p\) denotes the pressure. Equations (1.3) and (1.4) are Newton’s laws for linear and angular momenta of the body under the influence of the pressure force. Here we denote by \(m\) the mass of the rigid body (normalized so that the density of the fluid is \(\rho_F = 1\)), by \(x_B(t)\) the position of its center of mass, \(n(t, x)\) denotes the unit normal vector pointing outside the fluid and \(d\Gamma(t)\) denotes the surface measure on \(\partial \mathcal{S}(t)\). The time-dependent vector

\[
\ell(t) := x'_B(t)
\]

denotes the velocity of the center of mass of the solid and \(r\) denotes its angular speed, so that the solid velocity field is given by

\[
v(t, x) := \ell(t) + r(t) \times (x - x_B(t)).
\]

In (1.4) the \(3 \times 3\) matrix \(J = J(t)\) denotes the moment of inertia which depends on time according to Sylvester’s law

\[
J = QJ_0Q^*,
\]

where \(J_0\) is the initial value of \(J\) and where the rotation matrix \(Q \in SO(3)\) is deduced from \(r\) by the following differential equation (where we use the convention
to consider the operator $r(t) \times \cdot$ as a matrix):
\begin{equation}
Q(t) = r(t) \times Q(t) \quad \text{and} \quad Q(0) = \text{Id}_3.
\end{equation}
The matrix $J_0$ can be obtained as follows. Given a positive function $\rho_{S_0} \in L^\infty(S_0; \mathbb{R})$ describing the density in the solid (again normalized so that the density of the fluid is $\rho_F = 1$), the data $m, x_0$ and $J_0$ can be computed by its first moments
\begin{align}
m &= \int_{S_0} \rho_{S_0} \, dx > 0, \\
mx_0 &= \int_{S_0} x \rho_{S_0}(x) \, dx, \\
J_0 &= \int_{S_0} \rho_{S_0}(x) \left( |x - x_0|^2 \text{Id}_3 - (x - x_0) \otimes (x - x_0) \right) \, dx.
\end{align}
Finally, the domains occupied by the solid and the fluid are given by
\begin{equation}
S(t) = \left\{ x_B(t) + Q(t)(x - x_0), \ x \in S_0 \right\} \quad \text{and} \quad F(t) = \Omega \setminus \overline{S(t)},
\end{equation}
starting from a given initial position $S_0 \subset \Omega$, such that $J_0 := \Omega \setminus S_0$. Let us emphasize that $S(t)$ and $\partial \Omega$ being compact, and since $S(t) \subset \Omega$, the solutions that we consider satisfy
\begin{equation}
\text{dist}(S(t), \partial \Omega) > 0 \quad \text{on} \ [0, T].
\end{equation}
Let us give a precise definition of the classical solutions examined in this paper.

**Definition 1.1** (Classical solutions). We call a classical solution of the PDE formulation on $[0, T]$ a triple

\begin{equation}
(u, x_B, r) \in C^{1,\lambda}(\bigcup_{t \in [0, T]} \{ t \} \times F(t) ; \mathbb{R}^3) \times C^2([0, T]; \mathbb{R}^3) \times C^1([0, T]; \mathbb{R}^3),
\end{equation}

(for some $\lambda \in (0, 1)$) satisfying (1.1)–(1.19).

The local-in-time existence and uniqueness of classical solutions to the problem (1.1)–(1.19) holds when the initial velocity of the fluid is in the Hölder space $C^{1,\eta}$; cf. [5] for a precise statement. Let us also mention the earlier results of Ortega, Rosier and Takahashi [8]–[9] where the body-fluid system occupies the plane $\mathbb{R}^2$, Rosier and Rosier [10] in the case of a body in $\mathbb{R}^3$ and Honot, San Martin and Tucsnak [6] in the case (considered here) of a bounded domain, with the initial velocity in a Sobolev space $H^m, \ m \geq 3$.

1.2. Geodesic formulation. Let us now turn to the geometric viewpoint. We first describe below the infinite-dimensional space of configuration of the system.

Next we introduce a natural action, which allows us to define our notion of geodesic.

1.2.1. Rigid movements. Let us first describe the rigid part of the motion. To a velocity vector field $v$ of a rigid body one associates the flow
\begin{equation}
\partial_t \tau(t, x) = v(t, \tau(t, x)) \quad \text{and} \quad \tau(0, x) = x \quad \text{for} \ (t, x) \in [0, T] \times S_0.
\end{equation}
It is easy to integrate to find
\begin{equation}
\tau(t, x) = x_B(t) + Q(t)(x - x_0),
\end{equation}
where
\begin{equation}
x_B(t) := \tau(t, x_0),
\end{equation}
and where \( Q(t) \) is obtained from \( v \) by (1.14) and \( r \) is given by (1.12).

The flow \( \tau \) can be seen as a \( C^1 \) function of the time with values in the Lie group \( SE(3) \) of rigid motions (the special Euclidean group), that is, the group generated by translations and rotations in 3D. Its tangent space at \( \text{Id} \in SE(3) \) is

\[
\mathfrak{se}(3) := T_{\text{Id}} SE(3) = \left\{ v \in C^1(\mathbb{R}^3; \mathbb{R}^3) \mid D(v) = 0 \right\},
\]

where \( D(v) \) denotes the tensor of deformations \( 2D(v) := (\partial_i v_j + \partial_j v_i)_{i,j} \). Given \( x_B \in \mathbb{R}^3 \), we have the following:

\[
\mathfrak{se}(3) = \left\{ v : \mathbb{R}^3 \to \mathbb{R}^3 \mid \exists (\ell, r) \in \mathbb{R}^3 \times \mathbb{R}^3, \forall x \in \mathbb{R}^3, v(x) = \ell + r \times (x - x_B) \right\}.
\]

Moreover, given \( x_B \in \mathbb{R}^3 \) and \( v \in \mathfrak{se}(3) \), the ordered pair \((\ell, r)\) above is unique. Hence \( \mathfrak{se}(3) \sim \mathbb{R}^3 \times \text{Skew}_3(\mathbb{R}) \).

Accordingly, the tangent space of \( SE(3) \) at \( \tau \in SE(3) \) is

\[
T_{\tau} SE(3) := \left\{ v \circ \tau \text{ with } v \in \mathfrak{se}(3) \right\}.
\]

Now, \( x_0 \) being given, we introduce the following projections on \( T_{\tau} SE(3) \): to \( \sigma = v \circ \tau \in T_{\tau} SE(3) \) we associate \((L_\tau[\sigma], R_\tau[\sigma])\) as the unique ordered pair \((\ell, r)\) associated to \( v \) with \( x_B := \tau(x_0) \); in other words,

\[
\sigma(\tau^{-1}(x)) = v(x) = L_\tau[\sigma] + R_\tau[\sigma] \times (x - \tau(x_0)).
\]

Let us conclude this subsection by describing the energy of the solid. Using the choice of \( x_B(t) \) as the center of mass of the body at time \( t \), we have that

\[
(1.21) \quad \int_{S(t)} \rho_{S_0}(\tau_t^{-1}(x)) (x - x_B(t)) \, dx = 0,
\]

and therefore, for any \((\ell_1, r_1, \ell_2, r_2) \in (\mathbb{R}^3)^4\), for any \( t \),

\[
(1.22) \quad \int_{S(t)} \rho_{S_0}(\tau_t^{-1}(x)) (\ell_1 + r_1 \times (x - x_B(t))) \cdot (\ell_2 + r_2 \times (x - x_B(t))) \, dx = m \ell_1 \cdot \ell_2 + J(t) r_1 \cdot r_2,
\]

where \( J(t) \) is given by (1.13) and the notation \( \tau_t^{-1} \) stands for the inverse of the function \( \tau_t := \tau(t, \cdot) \).

**1.2.2. Fluid displacements and Arnold’s geodesic interpretation.** Let us briefly recall Arnold’s interpretation of the Euler equation. To a velocity vector field \( u \) satisfying the incompressible Euler equations in \( \Omega \) (without body) one associates the flow \( \eta \) defined on \([0, T] \times \Omega \) by

\[
(1.23) \quad \partial_t \eta(t, x) = u(t, \eta(t, x)) \text{ and } \eta(0, x) = x.
\]

The flow \( \eta \) can be seen as a continuous function of the time with values in the space \( \text{Sdiff}^+(\Omega) \) of the volume and orientation preserving diffeomorphisms defined in \( \Omega \). The latter is viewed as an infinite-dimensional manifold with the metric inherited from the embedding in \( L^2(\Omega; \mathbb{R}^3) \), and the tangent space in \( \eta \in \text{Sdiff}^+(\Omega) \) is

\[
T_\eta \text{Sdiff}^+(\Omega) := \left\{ u \circ \eta \text{ with } u \in C^1(\Omega; \mathbb{R}^3) \mid \text{div} (u) = 0 \text{ in } \Omega, \ u \cdot n = 0 \text{ on } \partial \Omega \right\}.
\]
Euler’s equations are then interpreted as a geodesic equation on \( \text{sdiff}^+(\Omega) \). The pressure field appears as a Lagrange multiplier for the divergence-free constraint on the velocity. Ebin and Marsden proved in [4] the existence of these geodesics when the initial velocity of the fluid is in the Sobolev space \( H^s(\Omega), s > \frac{5}{2} \).

1.2.3. Possible configurations of the fluid/body system as a Riemannian manifold.

To introduce the geodesic formulation of the motion of a rigid body immersed in an incompressible perfect fluid, we first describe the infinite-dimensional manifold on which these geodesics will be considered.

The set of the possible configurations as a Riemannian manifold. To begin with, we first describe the set of the possible configurations of the system at a fixed time by setting

\[
\mathcal{C} := \{ (\tau, \eta) \in SE(3) \times C^{1,\lambda}(\mathcal{F}_0; \mathbb{R}^3) \text{ such that } \tau(S_0) \subset \Omega, \}
\]

where \( \eta \) is a volume and orientation preserving diffeomorphism \( \mathcal{F}_0 \to \Omega \backslash \{\tau(S_0)\} \).

We will represent \( (\tau, \eta) \) by \( \phi : \Omega \to \Omega \) such that \( \phi|_{S_0} = \tau \) and \( \phi|_{\mathcal{F}_0} = \eta \). Note that \( \phi \) is not necessarily continuous.

Let us observe that according to the Helmoltz decomposition, in \( C^{1,\lambda}(\mathcal{F}_0; \mathbb{R}^3) \), the space of divergence-free vector fields is closed and admits a topological complement. Therefore, one can see that \( \mathcal{C} \) is a submanifold of a manifold modelled on the Banach space

\[
E := se(3) \times C^{1,\lambda}(\mathcal{F}_0; \mathbb{R}^3).
\]

We will be interested in the tangent space of this infinite-dimensional manifold. Let us first recall that by definition the tangent space \( T_{(\tau, \eta)}\mathcal{C} \) in \( (\tau, \eta) \in \mathcal{C} \) is the set of equivalence classes of germs of continuously differentiable function \( \Theta : (-\varepsilon, \varepsilon) \to \mathcal{C} \) (for some \( \varepsilon > 0 \)) such that \( \Theta(0) = (\tau, \eta) \), for the equivalence relation:

\[
(\psi_1, e_1) \equiv (\psi_2, e_2) \text{ if } D(\psi_2 \circ \psi_1^{-1})(\psi_1(\tau, \eta)) \cdot e_1 = e_2.
\]

Equivalently \( (\sigma, \mu) \in T_{(\tau, \eta)}\mathcal{C} \) is the set of equivalence classes of pairs \( (\psi, e) \) where \( \psi \) is a chart defined on a neighborhood of \( (\tau, \eta) \in \mathcal{C} \) and \( e \in E \) for the relation

\[
(\psi_1, e_1) \equiv (\psi_2, e_2) \text{ if } D(\psi_2 \circ \psi_1^{-1})(\psi_1(\tau, \eta)) \cdot e_1 = e_2.
\]

Clearly this makes \( T_{(\tau, \eta)}\mathcal{C} \) a linear space and \( T\mathcal{C} := \bigcup_{(\tau, \eta) \in \mathcal{C}} \{ (\tau, \eta) \} \times T_{(\tau, \eta)}\mathcal{C} \) a vector bundle whose base space is \( \mathcal{C} \).

Let us introduce the following notation: given \( (\tau, \eta) \in \mathcal{C} \) and \( \mu \in C^{1,\lambda}(\mathcal{F}_0; \mathbb{R}^3) \), we introduce \( U_\eta[\mu] : \eta(\mathcal{F}_0) \to \mathbb{R}^3 \) by

\[
U_\eta[\mu] := \mu \circ \eta^{-1}.
\]

Recall that due to the openness of \( \Omega \) and closedness of \( S_0 \) one has \( d(\phi(S_0), \partial\Omega) > 0 \) for \( \phi \in \mathcal{C} \).
Now the tangent space of $\mathcal{C}$ is described by the following proposition.

**Proposition 1.2.** Let $(\tau, \eta) \in \mathcal{C}$. Then using the notation
\begin{equation}
(1.24) \quad x_B := \tau(x_0), \; S := \tau(S_0) \text{ and } \mathcal{F} := \Omega \setminus S,
\end{equation}
we have
\begin{equation}
(1.25) \quad \text{div}(U_\eta[\mu]) = 0 \quad \text{in} \quad \mathcal{F},
\end{equation}
\begin{equation}
(1.26) \quad U_\eta[\mu](x) \cdot n(x) = (L_\tau[\sigma] + R_\tau[\sigma] \times (x - x_B)) \cdot n(x) \quad \text{on} \quad \partial S,
\end{equation}
\begin{equation}
(1.27) \quad U_\eta[\mu](x) \cdot n(x) = 0 \quad \text{on} \quad \partial \Omega
\end{equation}
As before, $n$ denotes the normal unit vector on $\partial \Omega$ and $\partial S$, pointing outside the fluid.

The proof of Proposition 1.2 will be given in the next section. We will represent $(\sigma, \mu)$ by $\mathcal{U} \circ \phi : \Omega \to \mathbb{R}^3$, where $\mathcal{U} : \Omega \to \mathbb{R}^3$ is given by $\mathcal{U}_S \circ \tau = \sigma$ and $\mathcal{U}_F = U_\eta[\mu]$. In the same way as $\phi$, $\mathcal{U}$ can be discontinuous.

The manifold $\mathcal{C}$ can be endowed by the following Riemannian metric: for any $\phi \in \mathcal{C}$, for any $\mathcal{U}_1 \circ \phi, \mathcal{U}_2 \circ \phi \in T_\phi \mathcal{C}$,
\begin{equation}
(1.28) \quad \langle \mathcal{U}_1 \circ \phi, \mathcal{U}_2 \circ \phi \rangle_\phi := \int_\Omega \rho_0(\phi^{-1}) \mathcal{U}_1 \cdot \mathcal{U}_2 \, dx.
\end{equation}

Above we used the density $\rho_0$ defined on $\Omega$ by
\begin{equation}
(1.29) \quad \rho_0(x) = \begin{cases} 
1 \text{ in } \mathcal{F}_0, \\
\rho_{S_0}(x) \text{ in } S_0.
\end{cases}
\end{equation}

Splitting the fluid flow and the solid one this reads: for any $(\sigma_1, \mu_1), (\sigma_2, \mu_2)$ in $T_{(\tau, \eta)} \mathcal{C}$, we have
\begin{equation}
(1.30) \quad (\sigma_1, \mu_1), (\sigma_2, \mu_2))_{(\tau, \eta)} = mL_\tau[\sigma_1] \cdot L_\tau[\sigma_2] + J[\tau]R_\tau[\sigma_1] \cdot R_\tau[\sigma_2] + \int_{\eta(F_0)} U_\eta[\mu_1] \cdot U_\eta[\mu_2] \, dx,
\end{equation}
where $J[\tau]$ is the inertia matrix deduced from the initial one $J_0$ by the rigid transformation $\tau$, that is,
\begin{equation}
(1.31) \quad J[\tau] = Q[\tau]J_0Q[\tau]^*,
\end{equation}
where $Q[\tau]$ is the rotation matrix canonically associated to $\tau$, that is, its linear part.

Let us stress that this metric defines a weaker topology than the original one on $\mathcal{C}$.

**Curves of configurations.** We now turn to time-dependent displacements. Let us be given $(\tau_0, \eta_0)$ and $(\tau_1, \eta_1)$ in $\mathcal{C}$. We introduce
\begin{equation}
(1.32) \quad \mathcal{L} := \left\{ (\tau, \eta) \in C^1([0, T]; \mathcal{C}) \right. \left. \text{ such that:} \right. \\
\quad \begin{aligned}
\quad \text{i.} & \quad \tau(0) = \tau_0, \; \eta(0) = \eta_0, \\
\quad \text{ii.} & \quad \tau(T) = \tau_1, \; \eta(T) = \eta_1,
\end{aligned}
\end{equation}
It is easy to verify that \( \mathcal{L} \) is a submanifold of a manifold modelled on the Banach space \( E_T := C^1([0, T]; \mathfrak{se}(3)) \times C^{1, \lambda}(\sigma); \mathfrak{se}(3)) \times C^{1, \lambda}(\mathfrak{se}(3)) \times \mathcal{F}_0; \mathbb{R}^3 \).

The tangent space of this manifold is described by the following proposition.

**Proposition 1.3.** Let \((\tau, \eta) \in \mathcal{L}\). Then using the notation
\[
(1.31) \quad x_B(t) := \tau_t(x_0), \quad S(t) := \tau_t(S_0) \quad \text{and} \quad \mathcal{F}(t) := \Omega \setminus S(t),
\]
we have
\[
T_{(\tau, \eta)} \mathcal{L} = \left\{ (\sigma, \mu) \in C^1([0, T]; T_\tau \mathfrak{se}(3)) \times C^{1, \lambda}(\sigma); \mathfrak{se}(3)) \times C^{1, \lambda}(\mathfrak{se}(3)) \times \mathcal{F}_0; \mathbb{R}^3 \right\}
\]
\[
(1.32) \quad \sigma(0) = \sigma(T) = 0 \quad \text{and} \quad \mu(0) = \mu(T) = 0,
\]
\[
(1.33) \quad \nabla_t (U_\eta[\mu]) = 0 \quad \text{in} \quad \mathcal{F}(t) \quad \text{for each} \quad t \in [0, T],
\]
\[
(1.34) \quad U_\eta[\mu] = n = (L_\tau[\sigma] + R_\tau[\sigma] \times [x - x_B(t)]) \cdot n \quad \text{on} \quad \partial S(t) \quad \text{for each} \quad t \in [0, T],
\]
\[
(1.35) \quad U_\eta[\mu] = n = 0 \quad \text{on} \quad \partial \Omega \quad \text{for each} \quad t \in [0, T].
\]

**Remark 1.4.** Here we make the abuse of notation \( C^1([0, T]; T_\tau \mathfrak{se}(3)) \), since actually \( T_\tau \mathfrak{se}(3) \) depends on \( t \). We consider \( \sigma \) as the section of a vector bundle rather than as a function. One can for instance interpret \( C^1([0, T]; T_\tau \mathfrak{se}(3)) \) as the set of mappings \( \sigma \) such that \((t, x) \mapsto \sigma(t, \tau_t^{-1}(x)) \) is in \( C^1([0, T]; \mathfrak{se}(3)) \). Also, we sometimes drop the dependence of the objects on \( t \) in order to simplify the notation.

Proposition 1.3 is the time-dependent counterpart of Proposition 1.2. We do not provide a proof since it is only a matter of adapting the proof of Proposition 1.2 with a harmless parameter. The only new point is to observe that the extremities of the curves being prescribed (the conditions i and ii in (1.30)), the fields \( \sigma \) and \( \mu \) vanish when \( t = 0 \) or \( T \).

As previously, we will represent \((\tau, \eta) \in \mathcal{L}\) by \( \phi : [0, T] \times \Omega \to \Omega \) such that for any \( t \in [0, T] \),
\[
\phi(t, \cdot)|_{S_0} = \tau(t, \cdot) \quad \text{and} \quad \phi(t, \cdot)|_{\partial S_0} = \eta(t, \cdot).
\]

We represent \((\sigma, \mu) \in T_{(\tau, \eta)} \mathcal{L} \) by \( U \circ \phi : [0, T] \times \Omega \to \mathbb{R}^3 \), where \( U : [0, T] \times \Omega \to \mathbb{R}^3 \) is given, for any \( t \in [0, T] \), by
\[
U(t, \cdot)|_{S(t)} \circ \tau_t(t, \cdot) = \sigma(t, \cdot) \quad \text{and} \quad U(t, \cdot)|_{\partial S(t)} = U_\eta[\mu](t, \cdot).
\]

**1.2.4. The geodesic interpretation of the motion of a rigid body immersed in an incompressible perfect fluid.** Here we consider geodesics as critical points of the following action on the manifold \( \mathcal{L} \):
\[
(1.36) \quad \mathcal{A}(\phi) := \frac{1}{2} \int_{[0, T] \times \Omega} \rho_0 |\partial_t \phi|^2 \, dx \, dt.
\]
We see that the action is obtained by integrating the squared norm (associated to the metric of \( \mathcal{L} \)) of the tangent vector to the curve \( \phi \), that is,
\[
\mathcal{A}(\phi) = \frac{1}{2} \int_{[0, T]} \langle \partial_t \phi(t, \cdot), \partial_t \phi(t, \cdot) \rangle \, dt.
\]
Separating the fluid and the body parts in the integral and using (1.22), we see that
\[
\mathcal{A}(\phi) = \frac{1}{2} \int_{[0, T]} \left( m |\ell(t)|^2 + \mathcal{J}[\tau(t)] r(t) \cdot r(t) + \int_{n(t)} |u(t, x)|^2 \, dx \right) \, dt,
\]
where
\[ \ell := L_\tau[\partial_t \tau], \quad r := R_\tau[\partial_t \tau] \quad \text{and} \quad u := U_\eta[\partial_t \eta]. \]

In this writing, we recognize the integral over time of the kinetic energy of the fluid-body system.

Moreover, going back to (1.36), since the action is a continuous quadratic form on \( L \), we deduce that \( A \) is differentiable on \( L \) with
\[
DA(\phi) \cdot (U \circ \phi) = \int_{[0,T] \times \Omega} \rho_0 \partial_t \phi \cdot \partial_t (U \circ \phi) \, dx \, dt
\]
\[
= \int_{[0,T]} \langle \partial_t \phi(t, \cdot), \partial_t (U \circ \phi)(t, \cdot) \rangle_{\phi(t, \cdot)} \, dt.
\]

This leads us to the following natural definition.

**Definition 1.5.** We say that \( \phi \in L \) is a geodesic on \( L \) if for any \( U \circ \phi \in T_\phi L \),
\[
DA(\phi) \cdot (U \circ \phi) = 0.
\]

### 1.3. Equivalence of the two points of view

The main result of this paper is the following.

**Theorem 1.6.** If \((u, x_B, r)\) is a classical solution of the PDE formulation on \([0, T]\), then \((\tau, \eta)\) defined by formulas (1.20) and (1.23) is a geodesic on \( L \).

Conversely, let \((\tau, \eta)\) \( \in L \) be a geodesic. Then \((u, x_B, r)\), where \((\ell, r, u)\) is defined by (1.37) and \( x_B \) is obtained by (1.10) and (1.11), is a classical solution of the PDE formulation on \([0, T]\) (in the sense of Definition 1.1).

Theorem 1.6 will be proved in Subsection 2.2.

**Remark 1.7.** Let us define the length of a curve \( \phi \in L \),
\[
\Lambda(\phi) := \int_{[0, T]} \left( \langle \partial_t \phi(t, \cdot), \partial_t \phi(t, \cdot) \rangle_{\phi(t, \cdot)} \right)^{1/2} \, dt,
\]
and consider
\[
d := \inf \Lambda(\phi)
\]
\[
= \inf \int_{[0, T]} \left( \ell(t)^2 + \mathcal{F}(t)r(t) \cdot r(t) + \int_{\mathcal{D}(t, \mathcal{O}_0)} |u(t, x)|^2 \, dx \right)^{1/2} \, dt,
\]
Theorem 2.2.

**Open Problem 1.** Is it possible to prove that for \( T \) small enough and \((\tau, \eta)\) \( \in L \) such that the associated \((u, x_B, r)\) is a classical solution of the PDEs formulation on \([0, T]\), one has for any \((\tilde{\tau}, \tilde{\eta})\) \( \in L \), \( A(\tau, \eta) \leq A(\tilde{\tau}, \tilde{\eta}) \), with equality if and only if \((\tilde{\tau}, \tilde{\eta}) = (\tau, \eta)\)? This should extend the result obtained by Brenier; cf. [2] in the case of a fluid without body.
Open Problem 2. Is it possible to adapt the strategy that Ebin and Marsden used in [4] in the case of a fluid alone to the case of one with a body, that is, to prove the existence of a free torsion connexion and of some geodesics by using parallel transport, and then to prove that these solutions also solve the PDE formulation?

Let us also mention studies connected with the stability properties of the system. In the case of a fluid alone, Arnold [1] uses a notion of Riemannian curvature to investigate the stability of two-dimensional stationary flows. In the case considered here of a fluid-body system, this stability was studied by Ilin and Vladimirov [13, 14].

2. Proofs

In this section, we prove the claims of Section 1. The existence of a solution of the PDE system will not be needed.

2.1. Proof of Proposition 1.2.

First step. Let us first show that any \((\sigma, \mu)\) satisfying (1.25)-(1.27) belongs to \(T_{(\tau, \eta)}C\). First, we define \(\theta_S \in C^1((\varepsilon, \varepsilon); SE(3))\) by

\[
\partial_s \theta_S(s)[x] = v_S(s, \theta_S(s)[x]), \quad \theta_S(0)[x] = \tau[x],
\]

where

\[
v_S(s, x) := L_\tau[\sigma] + R_\tau[\sigma] \times (x - x_B(s)), \quad x_B(s) := x_B + sL_\tau[\sigma],
\]

with \(\varepsilon > 0\) small. In particular we can require that for all \(s \in (-\varepsilon, \varepsilon)\),

\[
S_s := \theta_S(s)[S] \subset \Omega.
\]

Lemma 2.1. There exists a family \(\psi_s : \mathcal{F} \to \mathcal{F}_s := \Omega \setminus S_s\), for \(s \in (-\varepsilon, \varepsilon)\), smooth in its arguments, such that

\[
\begin{align*}
(2.1) & \quad \psi_0 = \text{Id}_{\mathcal{F}}, \\
(2.2) & \quad \forall s \in (-\varepsilon, \varepsilon), \; \psi_s = \theta_S(s) \text{ in a neighborhood of } S, \\
(2.3) & \quad \forall s \in (-\varepsilon, \varepsilon), \; \psi_s = \text{Id} \text{ in a neighborhood of } \partial \Omega, \\
(2.4) & \quad \forall s \in (-\varepsilon, \varepsilon), \; \forall x \in \mathcal{F}, \; \det(\nabla_x \psi_s) = 1.
\end{align*}
\]

Proof. We define

\[
V(s, x) := -\frac{1}{2} \text{curl} \left( \phi(x)(x \times L_\tau[\sigma]) + ||x - x_B(s)||^2 R_\tau[\sigma]) \right),
\]

where \(\phi\) is a smooth function equal to 1 in a neighborhood of \(S\) and equal to 0 in a neighborhood of \(\partial \Omega\). We associate \(\psi_s\) as the solution of

\[
\partial_s \psi_s(x) = V(s, \psi_s(x)), \quad \psi_0(x) = x.
\]

Equations (2.1) and (2.3) are straightforward. Equation (2.2) follows from the fact that \(V\) coincides with \(v_S\) in some neighborhood of \(\partial S\), reducing \(\varepsilon\) if necessary. Finally, since \(V\) is clearly divergence-free, (2.4) follows from Liouville’s theorem.

Now we construct the vector field:

\[
(2.6) \quad v_F(s, \cdot) := V(s, \cdot) + (\psi_s)_*(U_\eta[\mu] - V(0, \cdot)) \text{ in } \mathcal{F}_s.
\]

(Recall that the push-forward is defined as \((\psi_* v)(y) = d\psi_{\psi^{-1}(y)}[v(\psi^{-1}(y))].\)
Now we introduce a corresponding flow $\theta_F$ according to the $s$-variable, starting from $\theta_S$:

$$
\begin{align*}
\partial_s \theta_F(s, x) &= v_F(s, \theta_F(s, x)), \quad \text{in } (-\varepsilon, \varepsilon) \times F_0, \\
\theta_F(0, x) &= \eta(x) \text{ in } F_0.
\end{align*}
$$

(One can, for instance, smoothly extend $v_F(s, \cdot)$ to $\mathbb{R}^n$ to define this flow in a standard way.)

It remains to check that $\Theta := (\theta_S, \theta_F) \in C^1((-\varepsilon, \varepsilon); \mathcal{C})$, that $\Theta(0) = (\tau, \eta)$ and that $\Theta'(0) = (\sigma, \mu)$. The two latter claims come directly from the construction.

Let us prove that $\theta_F$ is volume preserving. To that purpose, we first notice that $\text{div}(U_s) = \text{div}(V(s)) = 0$. Using the fact that the push-forward of a divergence-free vector field by a diffeomorphism with unit Jacobian determinant is still divergence-free (see for instance [7, Proposition 2.4]), (2.4) and (2.6), we deduce that $v_F(s, \cdot)$ is divergence-free. Hence it follows that $\theta_F$ is volume preserving by Liouville’s theorem.

The main point, that is, that for any $s \in (-\varepsilon, \varepsilon)$, $\theta_F(s)$ sends $F_0$ to $F_s$, can be seen as follows. It suffices to prove that

$$
\begin{align*}
(2.7) & \quad v_F(s, \cdot).n = v_S(s, \cdot).n \text{ on } \partial S_s, \\
(2.8) & \quad v_F(s, \cdot).n = 0 \text{ on } \partial \Omega.
\end{align*}
$$

Using (2.5) and (2.6), we see that $v_F = U_\eta[\mu]$ in some neighborhood of $\partial \Omega$, so (2.8) is a consequence of (1.27). For what concerns (2.7), from (1.26) we see that $U_\eta[\mu] - v_S(0, \cdot)$ is tangent to $\partial S$. It follows that $(\psi_\tau)_*(U_\eta[\mu] - v_S(0, \cdot))$ is tangent to $\partial S_s$, which gives (2.7).

The other requirements, namely that $\theta_F$ is orientation preserving and has the claimed regularity, are clearly satisfied.

Second step. Conversely, given $(\sigma, \mu)$ in $T_{(\tau, \eta)}\mathcal{C}$, by definition of the tangent space, there is $\Theta = (\theta_S, \theta_F) \in C^1((-\varepsilon, \varepsilon); \mathcal{C})$ such that $\Theta(0) = (\tau, \eta)$ and that $\Theta'(0) = (\sigma, \mu)$. Let us check that (1.25)-(1.27) are satisfied.

First, it is obvious that $\sigma = \theta_F'(0) \in T_{\tau}SE(3)$. Next one can define

$$
\psi_\tau(s) := \partial_s \theta_F(s, \theta_F^{-1}(s, x))
$$

as a vector field on $F_s$. Then as

$$
\partial_s \theta_F(s, x) = v_F(s, \theta_F(s, x)),
$$

and since $\theta_F$ is volume preserving, by Liouville’s theorem we infer that $\text{div } v_F = 0$. Again using (2.9) and the fact that $\theta_F$ sends $F_0$ to $F_s$, we also easily infer (1.26) and (1.27). 

\section*{2.2. Proof of Theorem 1.6}

We start with the following lemma.

\textbf{Lemma 2.2.} For any $\phi = (\tau, \eta) \in \mathcal{L}$, for any $U \circ \phi \in T_\phi \mathcal{L}$,

$$
DA(\phi) \cdot (U \circ \phi) = \int_{[0,T]} \left( m \ell(t) \cdot \partial_t L_{\tau}[\sigma](t) + J[\tau] r(t) \cdot \partial_t R_{\tau}[\sigma](t) \\
+ \int_{F_0} \partial_t \eta(t, x) \cdot \partial_t (U(t, \eta(t, x))) \, dx \right) \, dt,
$$

where $\ell$ and $r$ are given by (1.37), $Q[\tau]$ is the linear part of $\tau$ and $J[\tau]$ is given by (1.29).
Proof. Let us split the fluid flow and the solid one in (1.38) and prove that

\[(2.10) \quad \int_{[0,T] \times S_0} \rho S_0 \partial_t \tau \cdot \partial_t \sigma \, dx \, dt = \int_{[0,T]} \left( m \ell \cdot \partial_t L_\tau[\sigma] + J[\tau] r \cdot \partial_t R_\tau[\sigma] \right). \]

Now in order to prove (2.10) we first perform a change of variable to get

\[(2.11) \quad \int_{[0,T] \times S_0} \rho S_0 \partial_t \tau \cdot \partial_t \sigma \, dx \, dt = \int_{[0,T]} \int_{S(t)} \rho S_0(\tau_t^{-1}(x)) \partial_t \tau(t, \tau_t^{-1}(x)) \cdot \partial_t \sigma(t, \tau_t^{-1}(x)) \, dx \, dt. \]

Now, by definition of \( \ell \) and \( r \) we have

\[(2.12) \quad \partial_t \tau(t, \tau_t^{-1}(x)) = \ell + r \times (x - x_B). \]

In particular, taking the linear part of these affine transformations and using the fact that the linear part of \( \partial_t \tau \) is \( \partial_t Q[\tau] \), we have

\[(2.13) \quad \partial_t Q[\tau] = r \times Q[\tau]. \]

On the other hand, by definition of \( L_\tau[\sigma] \) and \( R_\tau[\sigma] \), we have

\[\sigma = L_\tau[\sigma] + R_\tau[\sigma] \times (x - x_0),\]

so that, differentiating in time and using (2.13), we obtain

\[\partial_t \sigma = \partial_t L_\tau[\sigma] + (\partial_t R_\tau[\sigma]) \times Q[\tau](x - x_0) + R_\tau[\sigma] \times (r \times Q[\tau](x - x_0)).\]

Operating \( \tau_t^{-1} \) on the right for both sides of the previous equality, we get

\[(2.14) \quad \partial_t \sigma(t, \tau_t^{-1}(x)) = \partial_t L_\tau[\sigma] + \partial_t R_\tau[\sigma] \times (x - x_B) + R_\tau[\sigma] \times \left( r \times (x - x_B) \right).\]

We now plug (2.12) and (2.14) into the right hand side of (2.11) to obtain

\[(2.15) \quad \int_{[0,T] \times S_0} \rho S_0 \partial_t \tau \cdot \partial_t \sigma \, dx \, dt = \int_{[0,T]} (I_1(t) + I_2(t)) \, dt, \]

with

\[I_1(t) := \int_{S(t)} \rho S_0(\tau_t^{-1}(x)) \left( \ell(t) + r(t) \times (x - x_B(t)) \right) \cdot \left( \partial_t L_\tau[\sigma](t) + \partial_t R_\tau[\sigma](t) \times (x - x_B(t)) \right) \, dx, \]

\[I_2(t) := \int_{S(t)} \rho S_0(\tau_t^{-1}(x)) \left( \ell(t) + r(t) \times (x - x_B(t)) \right) \cdot \left( R_\tau[\sigma](t) \times (r(t) \times (x - x_B(t))) \right) \, dx. \]

We use the identity (1.72) with

\[\ell_1, r_1, \ell_2, r_2 = (\ell(t), r(t), \partial_t L_\tau[\sigma](t), \partial_t R_\tau[\sigma](t))\]

to get

\[(2.16) \quad I_1(t) = m \ell(t) \cdot \partial_t L_\tau[\sigma](t) + J[\tau(t)] r(t) \cdot \partial_t R_\tau[\sigma](t). \]
Finally we observe that

\[
I_2(t) = \int_{S(t)} \rho_{S_0}(\tau_t^{-1}(x)) \ell(t) \cdot \left( R_{\tau} [\sigma](t) \times \left[ r(t) \times (x - x_B(t)) \right] \right) \, dx
\]

\[
= \ell(t) \cdot \left( R_{\tau} [\sigma](t) \times \left[ \int_{S(t)} \rho_{S_0}(\tau_t^{-1}(x)) (x - x_B(t)) \, dx \right] \right)
\]

(2.17)

\[= 0,\]

according to (1.21). Combining (2.15), (2.16) and (2.17) yields (2.10).

\[\square\]

Proof of Theorem 1.6. First step. Let \((u, x_B, r)\) be a classical solution of the PDE formulation on \([0, T]\) and let \((\tau, \eta)\) be their respective flows given by formulas (1.20) and (1.23). Equation (1.1) reads

(2.18)

\[\frac{\partial^2 \eta}{\partial t^2} + (\nabla p) \circ \eta = 0, \text{ for } x \in F_0.\]

Let us now consider \((\sigma, \mu)\) in \(T(\tau, \eta)\). Using (2.18) and performing a change of variables, we get

\[- \int_{F_0} \frac{\partial^2 \eta}{\partial t^2} \cdot U_\eta[\mu] \circ \eta \, dx = - \int_{\partial F(t)} \nabla p \cdot U_\eta[\mu] \, dx.\]

Now using (1.33), (1.35) and Green’s formula we deduce that

\[- \int_{F(t)} \frac{\partial^2 \eta}{\partial t^2} \cdot U_\eta[\mu] \circ \eta \, dx = \int_{\partial S(t)} p U_\eta[\mu] \cdot n \, d\Gamma.\]

Now using (1.34) and then (1.3)-(1.4), we obtain

\[- \int_{F(t)} \frac{\partial^2 \eta}{\partial t^2} \cdot U_\eta[\mu] \circ \eta \, dx = \int_{\partial S(t)} p \left( L_{\tau} [\sigma] + R_{\tau} [\sigma] \times (x - x_B(t)) \right) \cdot n \, d\Gamma(x)
\]

\[= mx_B'(t) \cdot L_{\tau} [\sigma] + (J[\tau](t))' \cdot R_{\tau} [\sigma].\]

Then we integrate by parts over \([0, T]\) and conclude with Lemma 2.2 that \((\tau, \eta)\) is a geodesic on \(\mathcal{L}\).

Second step. Conversely, let \(\phi \in \mathcal{L}\) and conclude with Lemma 2.2 that \((\tau, \eta)\) is a geodesic on \(\mathcal{L}\).

It means that for any \((\sigma, \mu) \in T(\tau, \eta)\), one has

(2.19)

\[\int_{[0, T]} \left( m\ell(t) \cdot L_{\tau} [\sigma](t) + J[\tau](t) r(t) \cdot R_{\tau} [\sigma](t) \right.
\]

\[\left. + \int_{F_0} \partial_t \eta(t, x) \cdot \partial_t (U_r[\mu](t, \eta(t, x))) \, dx \right) \, dt = 0.\]

We first use (2.19) with \(\sigma = 0\). We consider \(w : [0, T] \times F_t \to \mathbb{R}^3\) satisfying

\[\text{div} \, w = 0 \text{ in } F_t, \ w \cdot n = 0 \text{ on } \partial F_t \text{ and } w(0, \cdot) = 0 \text{ and } w(T, \cdot) = 0.\]

Then
\( (\sigma, \mu) \in T_{(\tau, \eta)} \mathcal{L} \) for \( \sigma = 0 \) and \( \mu(t) := w(t, \eta(t,x)) \). Consequently, one has

\[
0 = \int_{[0,T]} \int_{\mathcal{F}_t} \partial_t \eta(t,x) \cdot \partial_t(w(t,\eta(t,x)))\,dx\,dt
\]
\[
= -\int_{[0,T]} \int_{\mathcal{F}_t} \partial_t^2(\eta(t,x) \cdot w(t,\eta(t,x))\,dx\,dt
\]
\[
= -\int_{[0,T]} \int_{\mathcal{F}_t} \partial_t^2(\eta(t,\eta^{-1}(t,x)) \cdot w(t,x)\,dx\,dt.
\]

It follows that \( \partial_t^2(\eta(t,\eta^{-1}(t,x)) \) is a gradient field in \( \mathcal{F}_t \). (that we denote by \( -\nabla p \).

Now going back to (2.19) we get that for general \( (\sigma, \mu) \in T_{(\tau, \eta)} \mathcal{L} \), one has

\[
\int_{[0,T]} \left( m\ell(t) \cdot \partial_t L_\tau(\sigma) + \mathcal{J}(\tau(t)) r(t) \cdot \partial_t(R_\tau(\sigma))(t) + \int_{\mathcal{F}_t} \nabla p(t,x) \cdot U_\eta[\mu](t,x)\,dx \right)\,dt = 0.
\]

Using Green’s formula for the last integral and \( (1.34)-(1.35) \), we deduce that for any \( \sigma \),

\[
\int_{[0,T]} \left( m\ell(t) \cdot \partial_t L_\tau(\sigma) + \mathcal{J}(\tau(t)) r(t) \cdot \partial_t(R_\tau(\sigma))(t) + \int_{\partial\mathcal{F}_t} p(t,x)n(x)\,d\Gamma + R_\tau(\sigma) \cdot \int_{\partial\mathcal{F}_t} p(t,x)(x-x_B(t)) \times n(x)\,d\Gamma \right)\,dt = 0.
\]

Now we integrate the first two terms by parts in time. Since this is valid for any \( \sigma \), hence for any \( L_\tau(\sigma) \) and \( R_\tau(\sigma) \), we infer \( (1.3)-(1.4) \). Equations \( (1.5)-(1.6) \) then follow from the very definition of \( \mathcal{L} \). \( \square \)
