strain be derivable from displacement (an irrotational vector is derivable from a potential).\(^2\)

The proof of the theorem rests on the fact that \(\sigma''_{ij}\) may be chosen as the solution to the following mixed boundary value problem for \(\sigma''_{ij}, u''_{ij}, \) and \(\epsilon''_{ij}:
\[
\begin{align*}
\sigma''_{ij,i} &= \sigma_{ij,i} + f^0_i \quad \text{in } V, \\
\epsilon''_{ij} &= L(\sigma''_{ij}) = \frac{1}{2}(u''_{ij,i} + u''_{ij,i}) \quad \text{in } V, \\
\sigma''_{ij}n_i &= \sigma_{ij}n_i - T^0_i \quad \text{on } S_B, \\
u''_{ij} &= u^0_i \quad \text{on } S_A.
\end{align*}
\]

Then the choice \(\sigma'_{ij} = \sigma_{ij} - \sigma''_{ij}\) satisfies
\[
\begin{align*}
\sigma'_{ij,i} &= -f^0_i \quad \text{in } V, \\
\sigma'_{ij}n_i &= T^0_i \quad \text{on } S_B,
\end{align*}
\]
and so \(\sigma'_{ij}\) and \(\sigma''_{ij}\) constitute the elements of the required decomposition.

Theorem 2. A symmetrical (strain) tensor \(\epsilon_{ij}\) defined in \(V\) may be written
\[
\epsilon_{ij} = \epsilon'_{ij} + \epsilon''_{ij},
\]
where \(\epsilon'_{ij}\) and \(\epsilon''_{ij}\) have the properties
\[
\begin{align*}
(c) \quad \epsilon''_{ij} &= \frac{1}{2}(u''_{ij,i} + u''_{ij,i}), \quad \text{where } u''_{ij}\text{ is a (displacement) vector that takes on the values } u^0_i\text{ on } S_A, \\
(d) \quad \text{the (stress) tensor } \sigma'_{ij} &= H(\epsilon'_{ij}), \quad \text{where } H\text{ is the inverse of } L, \text{ satisfies }
\end{align*}
\]
\[
\begin{align*}
\sigma'_{ij,i} &= -f^0_i \quad \text{in } V, \\
\sigma'_{ij}n_i &= T^0_i \quad \text{on } S_B.
\end{align*}
\]

This theorem follows immediately from the application of Theorem 1 to the stress tensor \(\sigma_{ij} = H(\epsilon_{ij})\) with the result that the decomposition \(\sigma_{ij} = \sigma'_{ij} + \sigma''_{ij}\) obeys conditions (a) and (b). Then the strain tensors \(\epsilon'_{ij} = L(\sigma'_{ij})\) and \(\epsilon''_{ij} = L(\sigma''_{ij})\) provide the elements of the required decomposition of \(\epsilon_{ij}\).

\(^2\)The reader is cautioned not to infer that \(\sigma''_{ij}\) satisfies the conventional Beltrami-Michell compatibility equations, since these involve equilibrium conditions that \(\sigma''_{ij}\) need not satisfy.

---

**ON VARIATIONAL PRINCIPLES AND GALERKIN'S PROCEDURE FOR NON-LINEAR ELASTICITY**

**By Bernard Budiansky and Carl E. Pearson (Harvard University)**

Variational principles are discussed by Greenberg [1] for the following problem of non-linear elasticity\(^*\)** in the region \(V\) bounded by the surface \(S = S_A + S_B:\)
\[
\begin{align*}
\sigma_{ij,i} &= 0 \quad \text{in } V, \\
\epsilon_{ij} &= \frac{1}{2}(u_{ij,i} + u_{ij,i}) \quad \text{in } V, \\
u_i &= u^0_i \quad \text{on } S_A, \\
\sigma_{ij}n_i &= T^0_i \quad \text{on } S_B.
\end{align*}
\]

\(^*\)Received December 20, 1955.

\(^**\)The non-linearity is incorporated only in the stress-strain relations; displacements are still assumed small.
where
\[ \epsilon_{ij} = \epsilon_{ij}(\sigma_{11}, \sigma_{12}, \ldots), \]
\[ \sigma_{ij} = \sigma_{ij}(\epsilon_{11}, \epsilon_{12}, \ldots). \]

The unambiguous formulation of the variational principles requires that the quantities \( \sigma_{ij} d\epsilon_{ij} \) and \( \epsilon_{ij} d\sigma_{ij} \) be exact differentials; it is accordingly assumed that \( \partial\sigma_{ij}/\partial\epsilon_{ij} = \partial\sigma_{ij}/\partial\epsilon_{ij} \) and that \( \delta\epsilon_{ij}/\delta\epsilon_{ij} = \delta\epsilon_{ij}/\delta\sigma_{ij} \). Then it is shown in (1) that

I. If \( u_i \) is a solution, with \( \epsilon_{ij} = \frac{1}{2}(u_{i,i} + u_{i,i}) \), then

\[ \delta \left[ \int_V \int_0^{\epsilon_{ij}} \sigma_{ij}(\epsilon_{11}, \epsilon_{12}, \ldots) \, d\epsilon_{ij} \, dV - \int_{S_B} T^0_{ij} u_i \, dS_B \right] = 0 \quad (1) \]

for all \( \delta u_i \) satisfying \( \delta u_i = 0 \) on \( S_A \). Here the upper limit in the inner integral of the first term is the \( \epsilon_{ij} \) state corresponding to the \( u_i \) solution.

II. If \( \sigma_{ij} \) is a solution, then

\[ \delta \left[ \int_V \int_0^{\sigma_{ij}} \epsilon_{ij}(\sigma_{11}, \sigma_{12}, \ldots) \, d\sigma_{ij} \, dV - \int_{S_A} u_i^0 \sigma_{ij} n_i \, dS_A \right] = 0 \quad (2) \]

for all \( \delta\sigma_{ij} \) satisfying \( \delta\sigma_{ij} = 0 \) in \( V \) and \( \sigma_{ij} n_i = 0 \) on \( S_B \). The upper limit of the inner integral in the first term is the \( \sigma_{ij} \) state of the solution.

In the practical application of these principles the procedure is to enforce (at least approximately) the satisfaction of Eqs. (1) and (2). The question therefore arises whether the following inverse theorems are valid:

III. If (1) holds for a particular \( u_i \) satisfying \( u_i = u_i^0 \) on \( S_A \), and for all \( \delta u_i \) satisfying \( \delta u_i = 0 \) on \( S_A \), then this \( u_i \) is a solution.

IV. If (2) holds for a particular \( \sigma_{ij} \) satisfying \( \sigma_{ij} = 0 \) in \( V \), \( \sigma_{ij} n_i = T^0_{ij} \) on \( S_B \), and for all \( \delta\sigma_{ij} \) satisfying \( \delta\sigma_{ij} = 0 \) in \( V \), \( \delta\sigma_{ij} n_i = 0 \) on \( S_B \), then this \( \sigma_{ij} \) is a solution.

As will be shown, the validity of III can be readily established by elementary means, but the proof of IV is less obvious. To prove III, we note that the volume integral in (1) may be transformed as follows:

\[ \delta \int_V \int_0^{\epsilon_{ij}} \sigma_{ij} \, d\epsilon_{ij} \, dV = \int_V \sigma_{ij} \delta\epsilon_{ij} \, dV = \int_V \sigma_{ij} \delta u_{i,i} \, dV \]

\[ = \int_V (\sigma_{ij} \delta u_i)_i \, dV - \int_V \sigma_{ij,i} \delta u_i \, dV. \]

Then use of Green's theorem and substitution back into (1) gives

\[ -\int_V \sigma_{ij,i} \delta u_i \, dV + \int_{S_B} (\sigma_{ij} n_i - T^0_{ij}) \delta u_i \, dS_B = 0. \]

It then follows from the freedom of choice available for \( \delta u_i \) that \( \sigma_{ij,i} = 0 \) in \( V \) and \( \sigma_{ij} n_i = T^0_{ij} \) on \( S_B \), and so, since \( u_i = u_i^0 \) on \( S_A \), it must be true that \( u_i \) is indeed a solution.

The verification of IV does not seem to be possible in so direct a fashion and so recourse will be made to the introduction of the following auxiliary theorem:

V. If \( \epsilon_{ij} \) is a (strain) field in \( V \) that satisfies the requirement

\[ \int_V \epsilon_{ij} \sigma_{ij} \, dV - \int_{S_A} u_i^0 \sigma_{ij} n_i \, dS_A = 0 \quad (3) \]
for all $\sigma_{ii}$ that obey the admissibility conditions $\sigma_{ii..i} = 0$ in $V$, $\sigma_{ii}n_i = 0$ on $S_B$, then $\epsilon_{ii}$ is derivable from a displacement field $u_i$ that equals $u_i^0$ on $S_A$.

The proof of $V$ depends on the proposition proved in [2] that $\epsilon_{ii}$ can be decomposed into $\epsilon_{ii} + \epsilon_{ii}''$, where $\epsilon_{ii}''$ is derivable from a $u''$ that equals $u_i^0$ on $S_A$, and $\epsilon_{ii}'$ provides, through Hooke's law, a stress $\sigma_{ii}' = H(\epsilon_{ii}')$ that satisfies $\sigma_{ii..i} = 0$ in $V$ and $\sigma_{ii}n_i = 0$ on $S_B$. Then (3) may be written as

$$\int_V \epsilon_{ii}'\sigma_{ii} dV + \int_V \epsilon_{ii}''\sigma_{ii} dV - \int_{S_A} u_i^0\sigma_{ii}n_i dS_A = 0.$$

By the principle of virtual work the last two integrals cancel for all admissible $u_i$, and the admissible choice of $\sigma_{ii} = H(\epsilon_{ii}')$ then gives

$$\int_V \epsilon_{ii}'H(\epsilon_{ii}') dV = 0.$$

But since the integrand is necessarily positive for $\epsilon_{ii} \neq 0$ (since it is essentially the strain-energy-density of linear elasticity) it follows that $\epsilon_{ii} = 0$. Hence $\epsilon_{ii} = \epsilon_{ii}'$, and so has the properties stated in $V$.

The proof of $IV$ is now immediate; from (2)

$$\int_V \epsilon_{ii}\delta\sigma_{ii} dV - \int_{S_A} u_i^0\delta\sigma_{ii}n_i dS_A = 0$$

for all admissible $\delta\sigma_{ii}$. Hence, by $V$, $\epsilon_{ii}$ is derivable from a $u_i$ that equals $u_i^0$ on $S_A$, and therefore $\sigma_{ii}$ is a solution.

The auxiliary theorem $V$ also provides a theoretical basis for the use of a Galerkin-type procedure in the approximate solution of non-linear elasticity problems. Such a procedure could consist of the following steps:

(a) Assume an approximate solution of the form

$$\sigma_{ii}^* = \sigma_{ii}^{(0)} + \sum_{k=1}^N a_k\sigma_{ii}^{(k)},$$

where

$$\sigma_{ii..i}^{(k)} = 0, \quad k = 0, 1, 2, \cdots, N$$

$$\sigma_{ii}^{(0)}n_i = T_i^0, \quad \text{on } S_B$$

$$\sigma_{ii}^{(k)}n_i = 0, \quad \text{on } S_B \quad \text{for } k = 1, 2, 3, \cdots, N$$

and where the constants $a_k$ are to be chosen so that

(b) $\int_V \epsilon_{ii}(\sigma_{ii}^*, \sigma_{ii}^*, \cdots)\lambda_{ii}^{(k)} dV - \int_{S_A} u_i^0\lambda_{ii}^{(k)}n_i dS_A = 0, \quad k = 1, 2, 3, \cdots, N$

where the $\lambda_{ii}^{(k)}$ are arbitrary symmetrical tensor fields that satisfy $\lambda_{ii..i}^{(k)} = 0$ in $V$ and $\lambda_{ii}^{(k)}n_i = 0$ on $S_B$.

The $\lambda_{ii}^{(k)}$ need not coincide with the $\sigma_{ii}^{(k)}$; if however they do coincide, this Galerkin procedure becomes equivalent to a Rayleigh-Ritz procedure based on (2) and the same expansion $\sigma_{ii}^*$.

All of the above results may be considered applicable to theories of plasticity of the deformation type if no "unloading" takes place (see [1]); in addition the various theorems can easily be generalized to the case of non-zero body force.
NOTE ON THE EQUATIONS OF SHALLOW ELASTIC SHELLS*

By P. M. NAGHDI (University of Michigan)

In the following, a system of differential equations is deduced for thin shallow elastic shells (of uniform thickness) with small displacements, which include the effect of transverse shear deformation. The corresponding equations of the classical theory, where the effect of transverse shear deformation is neglected, are contained in the works of Marguerre [1] and Green and Zerna [2], and have also been employed recently by E. Reissner [3, 4]. Although the equations sought may be obtained (through appropriate approximations) from the results given in [5], considerable space will be conserved if the basic equations of the theory are referred to Cartesian coordinates.

Let the equation of the middle surface of the shell be written in the form $z = z(x_1, x_2)$ and let: $w$ denote the displacement in the $z$-direction and $u_i$ and $\beta_i$ be respectively the displacements of the middle surface and the change of the slope of the normal to the middle surface, along the Cartesian coordinate axes $x_1$ and $x_2$. With the notation $N_{ii}$, $M_{ii}$, and $V_i$, for the stress resultants, stress couples, and transverse stress resultants, respectively, the stress differential equations of equilibrium are

$$N_{ii,i} + p_i = 0, \quad (1a)$$
$$V_{i,i} + [z_{i,i}N_{ii}],i + q = 0, \quad (1b)$$
$$V_i = M_{ii,i}, \quad (1c)$$

where comma denotes partial differentiation and $p_1$, $p_2$, and $q$ are the components of the load intensity in $x_1$, $x_2$, and $z$ directions, respectively.

The stress strain relations, which include the effect of transverse shear deformation, may be written as

$$\epsilon_{ii} = \frac{1}{2}[(u_{ii,i} + u_{i,i}) + (z,w_{i,i} + z,w_{i,i})] \quad (2a)$$
$$= \frac{1}{C} [\nu N_{kk} \delta_{ii} + (1 + \nu)N_{ii}],$$
$$M_{ii} = \frac{1}{2}D[2\nu \beta_{k,k} \delta_{ii} + (1 - \nu)(\beta_{i,i} + \beta_{i,i})], \quad (2b)$$
$$\beta_i = -w_{i,i} + \frac{6}{5Gh} V_i, \quad (2c)$$
