Boundary and Eigenvalue Problems in Mathematical Physics

Frame Analysis
By A. S. Hall and R. W. Woodhead, both of the University of New South Wales, Australia. An unusual book offering both Flexibility analysis and Stiffness analysis in one unifying treatment. Three dimensional frames containing curved members and members of varying sections are also dealt with in detail. 1961. Approx. 264 pages. Prob. $9.00.*

Handbook of Automation, Computation, and Control
Volume III: Systems and Components
Edited by Eugene M. Grabbe, Simon Ramo, and Dean E. Wooldridge, all of Thompson Ramo Wooldridge Inc. Classes of control components are described and it is shown how these components are combined to form complete systems. 1961. In Press.

The Physical Principles of Astronautics
Fundamentals of Dynamical Astronomy and Space Flight

Advanced Calculus
An Introduction to Analysis
By Watson Fulks, Oregon State College. A well-organized book placing emphasis on a rigorous re-examination of one-variable calculus, then the calculus of several variables with vector methods used extensively, and, finally, the theory of convergence as applied to series and improper integrals. 1961. Approx. 552 pages. Prob. $11.25.*

An Introduction to Linear Programming and the Theory of Games
By S. Vajda, Royal Naval Scientific Service, Great Britain. Leads to an understanding of the place of linear programming and the theory of games in modern operational research. 1960. 76 pages. $2.25.

Progress in Operations Research
Volume I
Edited by Russell Ackoff, Case Institute of Technology. This book inaugurates a series of review volumes which will "inventory" the mathematical techniques and research methods available to operations researchers. 1961. 520 pages. $11.50.

Transistor Logic Circuits
By Richard B. Hurley, International Business Machines, San Jose California. The first book of its kind to cover with thoroughness both logical mathematics, logical routines and blocks and the transistor circuits that implement the mathematics and blocks. 1961. Approx. 400 pages. Prob. $10.00.*

Quantum Mechanics
By Eugen Merzbacher, University of North Carolina. In a clear, expository style the author has written a text that offers a successful, contemporary, and sophisticated treatment of quantum mechanics and its application to simple physical systems. 1961. Approx. 580 pages. Prob. $11.00.*

Transmission of Information
A Statistical Theory of Communication

*Textbook edition available for college adoption. Send for examination copies.

OUTSTANDING TEXTS

Numerical Methods for Science and Engineering
by RALPH G. STANTON, University of Waterloo
Brings out the transition from hand calculations through desk calculations to electronic computers, as the complexity of problems increases. Contains completely solved numerical examples illustrating the principles and theory of numerical analysis in practice.
1961 288 pp. Text price $6.75

Games of Strategy: Theory and Applications
by MELVIN DRESHER, The Rand Corporation
Explores an elementary, mathematical treatment of the relatively new branch of mathematics, the theory of games of strategy. Relates rigorous theories of rational behavior and planning within competitive environments.
1961 224 pp. Text price: $6.75

For approval copies, write: Box 903, Dept. QAM

PRENTICE-HALL, Inc., Englewood Cliffs, N. J.
ELEMENTS OF THE THEORY OF MARKOV PROCESSES AND THEIR APPLICATIONS

A graduate-level text and reference in advanced statistics with numerous applications to several fields of science. The author presents an introduction to the theory of Markov processes, and also gives a formal treatment of mathematical models based on this theory which have been employed in various applied fields. The main emphasis is on application.

AN INTRODUCTION TO LINEAR STATISTICAL MODELS, VOL. I

This excellent text has been written to fulfill two needs: (1) for a theory textbook for seniors and first year graduate students in statistics, and (2) for a reference book in the area of regression, correlation, least squares, experimental design, etc., for consulting statisticians with limited mathematical training. Designed for a two-semester course.

MODERN MATHEMATICS FOR THE ENGINEER, Second Series

Edited by Edwin F. Beckenbach, University of California. University of California Engineering Extension Series. 480 pages, $9.50

A text for engineers, scientists, mathematicians, students, teachers and others who wish to become or remain informed concerning current applicable mathematical developments. Topics included have had recent spectacular applications in mathematics and are being increasingly applied in the physical, sociological and biological sciences.

INTRODUCTION TO MATRIX ANALYSIS

By Richard Bellman, The RAND Corporation. 328 pages $10.00

Three basic fields in the analysis of matrices are clearly covered, in this book—symmetric matrices and quadratic forms, matrices and differential equations, and positive matrices and their use in probability theory and mathematical economics. Also presented is part of the theoretical treatment of the use of matrices in the computational solution of ordinary and partial differential equations by means of digital computers.

SURVEY OF NUMERICAL ANALYSIS

The work of 14 nationally known authors, this book covers numerical analysis, both classical and modern, together with accounts of certain areas of mathematics and statistics which support it yet are not adequately covered in current literature. The first third of the book provides a basic training in numerical analysis and the remainder of the text is devoted to accounts of current practice in solving, by high speed equipment, special types of problems in the physical sciences, engineering and economics.

COMPLEX VARIABLES AND THE LAPLACE TRANSFORMATION FOR ENGINEERS

By Wilbur R. LePage, Syracuse University. International Series in Pure and Applied Mathematics. 415 pages, $12.50

330 West 42nd Street
New York 36, N. Y.
Send for copies on approval
BOOK REVIEWS

This little book, the first in a new series of "Methuen Monographs on Applied Probability and Statistics" presents on 105 pages a remarkably compact discussion of what is usually regarded as a rather rambling field: the mathematical theory of inventory control and water storage. In this country most attention has been focused on the first variant of this problem, the management of stocks of repair parts or other items with probabilistic demand so as to maximize some economic criterion of efficiency. This book offers a useful complement in that the dam interpretation of the problem, and those aspects of inventory control that bear most directly on water storage—on which the author is a leading authority—receive the most detailed treatment.

An introductory chapter presents some probability concepts; but the reader should have some knowledge of the probability calculus beforehand. The chapter on the inventory problem emphasizes the calculation of probabilities of states, such as shortages, but pays little regard to the discovery and calculation of optimal policies. A useful and interesting feature is the systematic discussion of various inventory problems that do not involve stochastic processes but can be disposed of as one-period problems. Segerdahl's theory of insurance risk is also presented in outline.

Throughout, the discussion is in terms of specific problems, and solutions are obtained for particular distributions, typically those of the Gamma family. Continuous time problems are analyzed by going to the limit with discrete approximations. The Monte Carlo or simulation method is used to deal with the complicated problems that arise in the study of sequences of dams.

In spite of its great variety of topics the book cannot achieve an adequate survey in its limited space. However, it is an excellent introduction on an elementary level to a field of operations research where much work is going on at the present.

Martin Beckmann

The present section of the Handbook of Supersonic Aerodynamics is part of a series, the first one of which was issued in 1950. This section deals, as the title indicates, with rarefied gas flows. It opens with a general survey of rarefied flow regimes. Unfortunately, the original description of rarefied flow regimes as put forward by Tsien is still propagated. Following this is a useful chapter on free molecule flow calculations, in which the aerodynamic and heat transfer coefficients for some bodies of simple geometry are presented. The following chapter presents a discussion of slip flow which this reviewer considers to be somewhat dated in the light of more recent advances. This little compendium does have a considerable amount of information, much of it in graphical form, that may be useful to those interested in a cursory view of the field.

Ronald F. Probstein

This useful dictionary contains more than 8500 entries from applied as well as pure mathematics. Extensive sampling did not reveal any incorrect entries. On the other hand, the temptation to increase the number of entries in a trivial manner has not always been resisted. For example, all of the entries "Axiom, Axiomatik, axiomatisch, axiomatisieren, Axiomatisierung, Axiomensystem" could well have been omitted, and the space gained could have been used to list less trivial correspondences, for instance "Drall—moment of momentum" or "Wirbelmoment—vortex strength."

W. Prager

(Continued on p. 38)

Though labelled "third edition", this is essentially an English translation of the second German edition (see this QUARTERLY, vol. 13, p. 348). The references have been brought up to date, many improvements have been made, and the number of examples has been increased.

William Prager

Part I (Perspectives) is concerned with the purpose and the historical development of operations research and systems engineering. Part II (Methodologies) is primarily devoted to the mathematical techniques. It contains chapters on simplified models (E. Naddor), basic statistics (A. J. Duncan), statistical quality control (A. J. Duncan), digital computers (W. C. Gore), inventory systems (E. Naddor), linear programming (V. V. McRae), queuing theory (C. D. Flagle), simulation techniques (C. D. Flagle), theory of games (E. Naddor), symbolic logic (W. E. Cushen), design of experiments (W. G. Cochran), human engineering (A. Chapanis), information theory (W. C. Gore), flow-graph representation of systems (W. H. Huggins), system dynamics (W. H. Huggins), and feedback and stability (N. H. Chosky). In Part III, the use of these principles and methods in operations research and systems engineering is illustrated by case studies.

W. Prager

This is the first volume of a new series, which is to be primarily devoted to the "basic principles and mathematical techniques of continuum mechanics, in all its aspects, together with experimental work of a fundamental kind". As the space available for this review is totally inadequate for a critical discussion of the eight articles, the following highly condensed table of contents will have to indicate the character of the volume.

Matrices of transmission in beam problems, by K. Marguerre (Vibrating beam—Matrices for points of discontinuity—Rigid supports—matrix—"Stiff" supports—Application of matrix method to more complex problems).

Dispersion relations for elastic waves in bars, by W. A. Green (Exact solutions—Elementary approximate theory—Approximate methods—High frequency solutions for a circular cylinder).

(Continued on p. 50)
Continuous distributions of dislocations, by B. A. Bilby (Burgers vector and torsion tensor—Shape, lattice and dislocation deformations—Zero lattice pure strain—Dislocation density and stress—Generalized spaces).

Asymmetric problems of the theory of elasticity for a semi-infinite solid and a thick plate, by R. Muki (Solution of the equations of equilibrium by Hankel transforms—Solution of the thermo-elastic equations by Hankel transforms—Stresses in a semi-infinite elastic solid under the compressive action of a rigid body—Stresses in a semi-infinite elastic solid with a tangential load on its surface—Thermal stresses in a semi-infinite elastic solid and a thick plate under steady distribution of temperature).

W. Prager

Consider a physical system $S$ represented at any time $t$ by a state vector $x(t)$. The classical description of the unfolding of the system over time uses an equation of the form $x(t) = F(x(s), s \leq t)$, where $F$ is a prescribed operation upon the function $x(s)$ for $s \leq t$. In certain simple cases, this reduces to the usual vector differential equation $dx/dt = g(x)$, $x(0) = c$.

For a variety of reasons, it is sometimes preferable to renounce a deterministic description and to introduce stochastic variables. If we take $x(t)$ to be a vector whose $i$-th component is now the probability that the system is in state $i$ at time $t$, and allow only discrete values of time, we can in many cases describe the behavior of the system over time quite simply by means of the equation $x(t + 1) = Ax(t)$. Here $A = (a_{ij})$, $i, j = 1, 2, \ldots, N$, is a transition matrix whose element $a_{ij}$ is the probability that a system in state $j$ at time $t$ will be found in state $i$ at time $t + 1$. Processes of this type are called Markov processes and are fundamental in modern mathematical physics.

So far we have assumed that the observer plays no role in the process. Let us now assume that in some fashion or other the observer has the power to choose the transition matrix $A$ at each stage of the process. We call a process of this type a Markovian decision process. It is a special, and quite important, type of dynamic programming processes; cf. Chapter XI of Dynamic Programming, Princeton University Press, 1957.

Let us suppose that at any stage of the process, we have a choice of one of a set of matrices, $A(q) = (a_{ij}(q))$. Associated with each choice of $q$ and initial state $i$ is an expected single-stage return $b_i(q)$. We wish to determine a sequence of choices which will maximize the expected return from $n$ stages of the process. Denoting the maximum expected return from an $n$-stage process by $f_i(n)$, the principle of optimality yields the functional equation

$$f_i(n) = \max_e \left[ b_i(q) + \sum_{i=1}^{N} a_{ij}(q)f_j(n - 1) \right].$$

As in the case of the ordinary Markov process, a question of great significance is that of determining the asymptotic behavior as $n \to \infty$. It is reasonable to suspect, from the nature of the underlying decision process, that a certain steady-state behavior exists as $n \to \infty$. This can be established in a number of cases.
The author does not discuss these matters at all. This is unfortunate, since there is little value to steady-state analysis unless one shows that the dynamic process asymptotically approaches the steady-state process as the length of the processes increases. Furthermore, it is essential to indicate the rate of approach.

The author sets himself the task of determining steady-state policies under the assumption of their existence. Granted the existence of a "steady-state," the function \( f_i(n) \) has the asymptotic form \( nc + b_i + o(1) \) as \( n \to \infty \) where \( c \) is independent of \( i \). The recurrence relations then yield a system of equations for \( c \) and the \( b_i \).

This system can be studied by means of linear programming as a number of authors have realized; cf. A. S. Manne, "Linear programming and sequential decisions," *Management Science*, vol. 6, 1960, pp. 259–268.

Howard uses a different technique based upon the method of successive approximations, in this case an approximation in policy space. It is a very effective technique as the author shows by means of a number of interesting examples drawn from questions of the routing of taxicabs, the auto replacement problem and the managing of a baseball team.

The book is well written and attractively printed. It is heartily recommended for anyone interested in the fields of operations research, mathematical economics, or in the mathematical theory of Markov processes.

Richard Bellman

An extensive handbook of shock tube technique. The first part, on the theory and performance of simple shock tubes, is by I. I. Glass. The second part, on the production of strong shocks and the application, design and instrumentation of shock tubes, is by J. G. Hall.
