CONSERVED QUANTITY PARTITION FOR DIRAC'S EQUATION*

By
THOMAS P. BRANSON

Institute for Advanced Study

Abstract. Let $M$ be the $(n+1)$-dimensional Minkowski space, $n > 3$. The energy of a solution $\psi$ to Dirac's equation in $M$ is a sum of $n$ terms, the $j$th term depending on $\psi$ and the space derivative $\partial \psi / \partial x_j$. We show that if the Cauchy datum for $\psi$ is compactly supported, then each of these terms is eventually constant. Specifically, if $\psi$ is initially supported in the closed ball of radius $b$ about the origin in space ($\mathbb{R}^n$), then for times $|t| \geq b$, the $j$th term is equal to the energy of the $j$th Riesz transform $(-\Delta)^{-1/2}(\partial / \partial x_j)\psi$, which also solves Dirac's equation.

We give similar results for other conserved quantities, which arise due to the conformal invariance of Dirac's equation, in place of the energy. The Lorentz quantities are eventually partitioned into a number of linear functions of the time, while the zeroth inversional (or "conformal") quantity is partitioned into quadratic functions of the time.

0. Introduction. In [5], Duffin used the Paley-Wiener Theorem of Fourier analysis to prove energy equipartition for the wave equation, a result first explicitly stated and proved by Lax and Phillips in [7]. Specifically, the statement is that the energy of a classical solution to the wave equation, compactly supported in space at some fixed time, is partitioned in finite time into exactly equal kinetic and potential parts. Though the result is stated in [5] for 3 space dimensions, the same proof goes through for odd space dimension $n \geq 3$. In [4], Dassios uses the same method to prove finite time energy equipartition (into equal electric and magnetic parts) for Maxwell's equations. Again, the result can be stated and proved for odd space dimension $n \geq 3$ (the electromagnetic field being an $(n+1)/2$-form).

In [1] and [2], the author considered the problem of partitioning the "higher" conformal conserved quantities for the wave and Maxwell equations. It was shown that under the same compact support assumption on Cauchy data, the conserved quantities coming from Lorentz invariance are partitioned in finite time into a number of linear functions of the time $t$, and that the "zeroth inversional", or "conformal" conserved quantity is partitioned into quadratic functions of $t$. These theorems resulted from a partitioning of certain first and second moments of the energy into kinetic and potential (or electric and magnetic) parts.

* Received November 12, 1982. The author was partially supported by NSF Grant MCS-8108814(A01).
Dirac's equation is also conformally invariant, and our purpose here is to determine how the energy, Lorentz quantity, and zeroth inversional quantity (all of which can be calculated using the Lagrangian formalism) are partitioned. Dirac's equation differs from the wave and Maxwell equations in that there is no separation between kinetic and potential energy, and in that the energy is not positive. Instead of an equipartition of energy, we find a partition into \( n \) terms, each of which is constant after finite time. These eventual constant values are the energies of the various Riesz transforms \((-\Delta)^{-1/2}(\partial/\partial x_j)\psi\) of the original solution \(\psi\). (These transforms also solve Dirac's equation.) It is important to note (see Remark 5.e below) that this result is not only different from the energy equipartition result given by Costa and Strauss in [3], but deals with an entirely different conserved quantity.

Longer calculations of the type used for the energy give the desired results on partition of the higher conserved quantities.

The approach used here for Dirac's equation can also be applied to the wave equation to further partition the potential energy. If \(u = u(x, t)\) is a solution of the wave equation with \(u(\cdot, 0)\) and \((\partial u/\partial t)(\cdot, 0)\) supported in \(\{|x| \leq b\}\), then for \(|t| \gg b\), each of the \(n\) terms \(\frac{1}{2} \|\partial u/\partial x_j\|_{L^2}^2\) in the potential energy of \(u\) is constant. The same idea applied to moments of the energy leads to further partitioning of the Lorentz and zeroth inversional quantities.

The paper is organized as follows. In Sec. 1, we standardize notation and record the conformal conservation laws associated with Dirac's equation. In Sec. 2, we partition the energy, in Sec. 3 the Lorentz quantities, and in Sec. 4 the inversional quantity. In Sec. 5, we make some remarks and state some related results, including the new results for the wave equation described above.

1. Dirac's equation and associated conservation laws. Fix an odd integer \(n \geq 3\), and let \(M\) be the \((n + 1)\)-dimensional Minkowski space, with coordinate functions \((x, t) = (x_1, \ldots, x_n, t)\). For our purposes, a spinor on \(M\) is a \(C^\infty\) function \(\psi : M \to \mathbb{C}^N\), where \(N = 2(n+1)/2\). Dirac's equation is

\[
\dot{\psi} = \sum_{j=1}^{n} \alpha_j \partial_j \psi,
\]

where the dot denotes \(\partial/\partial t\), \(\partial_j = \partial/\partial x_j\), and the \(\alpha_j\) are \(N \times N\) complex matrices satisfying

\[
\alpha_j \alpha_k + \alpha_k \alpha_j = 2\delta_{jk}, \tag{1.2}
\]

\[
\alpha_j^* = \alpha_j. \tag{1.3}
\]

In terms of the so-called "\(\gamma\)-matrices" on \(M\), \(\alpha_j = \gamma_j \gamma_0\), where \(\gamma_0\) is the matrix corresponding to the time coordinate. The particular representation of the relations (1.2) and (1.3), and even the dimension \(N\) of the representation space, will be immaterial to the results below.

Let \((\cdot, \cdot)\) and \(\|\|\) denote the usual inner product and norm in \(\mathbb{C}^N\), and let \(\langle \langle \cdot, \cdot \rangle \rangle\) and \(\|\|\|\) be the inner product and norm in \(L^2(\mathbb{R}^n, \mathbb{C}^N)\);

\[
\langle \langle \psi, \psi' \rangle \rangle = \int_{\mathbb{R}^n} \langle \psi(x), \psi'(x) \rangle \, dx.
\]
Let $\mathcal{S}$ denote the taking of the imaginary part. As a consequence of its conformal invariance, Dirac's equation admits $(n + 2)(n + 3)/2$ independent conserved quantities. These are the integrals over space ($\mathbb{R}^n$) of the densities [6]

$$
e = \mathcal{S} \left\langle \sum_j \alpha_j \partial_j \psi, \psi \right\rangle \quad \text{(energy density)},$$

$$p_j = \mathcal{S} \left\langle \partial_j \psi, \psi \right\rangle \quad \text{(linear momentum densities)},$$

$$\lambda_{jk} = x_j p_k - x_k p_j - \frac{1}{2} \mathcal{S} \left\langle \alpha_j \psi, \alpha_k \psi \right\rangle \quad \text{(angular momentum densities)},$$

$$b_j = \tau p_j + x_j e \quad \text{(Lorentz densities)},$$

$$h = t e + \sum_j x_j p_j \quad \text{(dilational density)},$$

$$i_0 = (r^2 + t^2) e + 2t \sum_j x_j p_j \quad \text{(zeroth inversional density)},$$

$$i_j = -2tx_j e - 2x_j \sum_k x_k p_k + (r^2 - t^2) p_j + \sum_k \mathcal{S} \left\langle x_k \alpha_j \psi, \alpha_k \psi \right\rangle \quad \text{($j$th inversional density}).$$

Here and below, the indices $j, k, m,$ and $q$ run from 1 to $n$, and $r^2 = \sum_j x_j^2$. The integrals are conserved (with suitable decay assumptions on $\psi$) because the time derivative of each density is an exact divergence:

$$\dot{e} = \sum_k \partial_k \left( \mathcal{S} \left\langle \sum_j \alpha_j \partial_j \psi, \alpha_k \psi \right\rangle \right) \equiv \nabla \cdot \beta,$$

$$\dot{p}_j = \sum_k \partial_k \left( \mathcal{S} \left\langle \partial_j \psi, \alpha_k \psi \right\rangle \right) \equiv \nabla \cdot \pi_j,$$

$$\dot{\lambda}_{jk} = \nabla \cdot (x_j \pi_k - x_k \pi_j) + \frac{1}{2} \sum_m \partial_m \left( \mathcal{S} \left\langle \alpha_j \alpha_k \alpha_m \psi, \psi \right\rangle \right),$$

$$\dot{b}_j = t \nabla \cdot \pi_j + \nabla \cdot (x_j \beta) + \frac{1}{2} \sum_k \partial_k \left( \mathcal{S} \left\langle \alpha_j \psi, \alpha_k \psi \right\rangle \right),$$

$$\dot{h} = t \nabla \cdot \beta + \nabla \cdot \left( \sum_j x_j \pi_j \right),$$

$$\dot{i}_0 = \nabla \cdot (r^2 \beta) + t^2 \nabla \cdot \beta + 2t \sum_j \nabla \cdot (x_j \pi_j) - \sum_j \partial_j \left( \mathcal{S} \left\langle x_k \alpha_j \psi, \alpha_k \psi \right\rangle \right),$$

$$\dot{i}_j = -2t \nabla \cdot (x_j \beta) - 2 \sum_k \nabla \cdot (x_j x_k \pi_k) + \nabla \cdot (r^2 \pi_j) - t^2 \nabla \cdot \pi_j - t \sum_k \partial_k \left( \mathcal{S} \left\langle \alpha_j \psi, \alpha_k \psi \right\rangle \right) - \sum_m \partial_m \left( \mathcal{S} \left\langle x_k \alpha_j \alpha_k \alpha_m \psi, \psi \right\rangle \right).$$

The conserved integrals will be denoted $E, P_j, \Lambda_{jk}, B_j, H, I_0, I_j$; for example, $E = \int \mathbb{R}^n e \, dx$. ($E$ and $H$ are not to be confused with electric and magnetic fields.) When dealing with more than one Dirac spinor, we write $E = E(\psi), P_j = P_j(\psi)$, etc. Our main results concern $E$ (Sec. 2), $B_j$ (Sec. 3), and $I_0$ (Sec. 4).
2. Energy partition. Let denote Fourier transformation in the $x$ variables: if $f$ is a $C^\infty$ function of $x$ and $t$, say Schwartz class in $x$ for fixed $t$, then

$$\hat{f}(\xi, t) = (2\pi)^{-n/2} \int_{\mathbb{R}^n} e^{ix\cdot\xi} f(x, t) \, dx,$$

where $dx$ is Lebesgue measure. (The dependence on $t$ will sometimes be suppressed.) The Fourier transform of a spinor is defined component by component, i.e., by $(\hat{\psi})_\lambda = (\psi_\lambda )^*$ for $\lambda = 1, \ldots, N$. We record the identities

$$(\partial_j \psi)^* = \frac{1}{i} \xi_j \hat{\psi}, \quad (x_j \psi)^* = \frac{1}{i} \partial_j \hat{\psi}.$$ 

(We shall rely on the context to distinguish between $\partial_j = \partial/\partial x_j$ and $\partial_j = \partial/\partial \xi_j$.)

In $\xi$-space, let $\rho = \sum_j \xi_j^2$ and $\theta_j = \xi_j/\rho$. We define the Riesz transforms

$$R_j \psi = \frac{\partial_j}{\sqrt{-\Delta}} \psi = \left( \frac{1}{i} \theta_j \hat{\psi} \right)^*, \quad \psi \in L^2.$$ 

Similarly, we have the iterated Riesz transforms

$$-R_j R_k \psi = \frac{\partial_j \partial_k}{\Delta} \psi = \left( \theta_j \theta_k \hat{\psi} \right)^*, \quad \psi \in L^2.$$ 

Our energy partition result states that for Dirac spinors with compact support in space at time 0, the summand $\frac{d}{d\lambda} \left\langle \left\langle \alpha_j \partial_j \psi, \psi \right\rangle \right\rangle$ (fixed $j$) in $E(\psi)$ eventually takes on the exact value $E(R_j \psi)$. (Note that a Riesz transform of a solution to (1.1) is again a solution.) Two remarks on notation are important: (1) Summation over repeated indices is never implied; all intended summation signs are explicitly supplied; (2) $\psi_t$ will denote $\psi(\cdot, t)$, and never the time derivative of $\psi$, which is denoted $\dot{\psi}$.

**Theorem 2.1.** If $\psi$ solves (1.1) and $\psi_0 = \psi(\cdot, 0)$ is supported in $\{ r \leq b \}$, then for $|t| \geq b$,

$$\frac{d}{dt} \left\langle \left\langle \alpha_j \partial_j \psi, \psi \right\rangle \right\rangle = \frac{d}{dt} \left\langle \left\langle \sum_k \alpha_k \partial_k \psi_0, \frac{\partial^2}{\Delta} \psi_0 \right\rangle \right\rangle. \tag{2.1}$$

Thus the left side of (2.1) takes on the value of the constant of motion $E(R_j \psi)$ for $|t| \geq b$.

For the proof, we apply the Paley-Wiener Theorem according to the method of Duffin [5] (see also [4, 1, 2]).

**Definition 2.2.** A (possibly vector-valued) function $f(z)$ of one complex variable is of exponential type $a > 0$ if for each $\epsilon > 0$, there is a constant $A_\epsilon$ with $|f(z)| \leq A_\epsilon e^{(a+\epsilon)|z|}$.

**Theorem 2.3 (Paley-Wiener).** Let $f(z)$ be an entire function (possibly vector-valued), of exponential type $a$, and of class $L^1$ on the real axis. Then the Fourier transform of the restriction of $f(z)$ to the real axis is zero outside $[-a, a]$.

**Proof of Theorem 2.1.** By (1.2), the components of $\psi$ solve the wave equation: $\ddot{\psi} = \Delta \psi$. Fourier transforming, we find that $\hat{\psi}(\xi)$ is a solution of the ordinary differential equation

$$\ddot{u} + \rho^2 u = 0, \tag{2.2}$$
with initial data
\[ u_0 = \hat{\psi}_0(\xi), \quad \dot{u}_0 = \frac{1}{i} \sum_k \alpha_k \xi_k \hat{\psi}_0(\xi). \]  

(The compact support assumption allows us to interchange \( \hat{\cdot} \) and \( \cdot \). Since the wave equation has finite propagation speed, \( \hat{\psi} \) has compact spatial support at each fixed time.)
The problem (2.2), (2.3) has the explicit solution
\[ u_t = \hat{\psi}_t(\xi) = \hat{\psi}_0(\xi) \cos \rho t + \frac{1}{i} \sum_k \alpha_k \theta_k \hat{\psi}_0(\xi) \sin \rho t. \]  

Now \( \langle (1/i) \alpha_j \psi_t, \hat{\psi}_t \rangle = \langle (1/i) \alpha_j \hat{\psi}_t, \hat{\psi}_t \rangle \), but (2.4), together with the trigonometric identities
\[
\cos^2 \xi = \frac{1}{2}(1 + \cos 2\xi), \\
\sin^2 \xi = \frac{1}{2}(1 - \cos 2\xi), \\
\sin \xi \cos \xi = \frac{1}{2} \sin 2\xi,
\]
yields
\[
\langle (1/i) \alpha_j \hat{\psi}_t, \hat{\psi}_t \rangle = \frac{1}{4} (X_0 + X_2) + \frac{1}{4} (X_0 - X_2) \cos 2\rho t + \frac{1}{2} X_1 \sin 2\rho t,
\]
where
\[
X_0 = \langle \frac{1}{i} \alpha_j \hat{\psi}_0, \hat{\psi}_0 \rangle, \\
X_1 = \langle 2 \langle \alpha_j \hat{\psi}_0, \sum_k \alpha_k \theta_k \hat{\psi}_0 \rangle \rangle, \\
X_2 = \langle -\frac{1}{i} \alpha_j \hat{\psi}_0, \hat{\psi}_0 \rangle + \frac{2}{i} \langle \sum_k \alpha_k \xi_k \hat{\psi}_0, \theta_j^2 \hat{\psi}_0 \rangle. \\
\]
(The formula for \( X_2 \) involves some simplification using (1.2) and (1.3).) Integrating over \( \xi \), we get
\[
\langle (1/i) \alpha_j \hat{\psi}_t, \hat{\psi}_t \rangle = \langle \frac{1}{i} \sum_k \alpha_k \xi_k \hat{\psi}_0, \theta_j^2 \hat{\psi}_0 \rangle \rangle \\
+ \frac{1}{4} \int_{\mathbb{R}^n} (X_0 - X_2) \cos 2\rho t \, d\xi + \frac{1}{2} \int_{\mathbb{R}^n} X_1 \sin 2\rho t \, d\xi. \]  

We would like to show that the integral terms in (2.6) vanish for \( |t| \gg b \).
Switching to spherical coordinates, the integral terms become
\[
\frac{1}{2} \int_0^\infty \rho^{n-1} \left( \int_{S^{n-1}} (X_0 - X_2) \, d\theta \right) \cos 2\rho t \, d\rho \\
+ \frac{1}{2} \int_0^\infty \rho^{n-1} \left( \int_{S^{n-1}} X_1 \, d\theta \right) \sin 2\rho t \, d\rho,
\]
where $d\theta$ is the usual measure on the unit sphere $S^{n-1}$. Let $\theta = (\theta_1, \ldots, \theta_n)$, so that $\xi = \rho \theta$. (The $\theta_j$ are not angular variables, but components of the unit vector in the direction $\xi$.) By definition,

$$\hat{\psi}_0(\xi) = \hat{\psi}_0(\rho \theta) = (2\pi)^{-n/2} \int_{\{r \leq b\}} e^{i\rho x \cdot \theta} \psi_0(x) \, dx.$$  

With $\theta$ fixed, this integral converges for all complex $\rho$, yielding an entire extension of $\hat{\psi}_0$, of exponential type $b$, and of Schwartz class in real $\rho$. The same is true for $\hat{\psi}_0$, though the extension of $\hat{\psi}_0$ is not the complex conjugate of the extension of $\hat{\psi}_0$; in the integral formula, $\psi_0$ is conjugated and the $i$ in the exponent is changed to $-i$, but the $\rho$ is not conjugated. Since $\xi_k = \rho \theta_k$, the $X_p$ extend, for fixed $\theta$, to entire functions of $\rho$ of exponential type $2b$, of Schwartz class in real $\rho$. (Multiplication by a polynomial in $\rho$ does not change the exponential type.) Furthermore,

$$X_p(-\rho, -\theta) = X_p(\rho, \theta), \quad p = 0, 2;$$

$$X_1(-\rho, -\theta) = -X_1(\rho, \theta).$$

Thus

$$Y_0 = \rho^{n-1} \int_{S^{n-1}} (X_0 - X_2) \, d\theta,$$

$$Y_1 = \rho^{n-1} \int_{S^{n-1}} X_1 \, d\theta$$

are entire, of exponential type $2b$, and of class $L^1$ in real $\rho$. Because $n - 1$ is even, $Y_0$ is even and $Y_1$ is odd. This means that the integral terms in (2.5) are equal to

$$\frac{\sqrt{2\pi}}{2} \left( \hat{Y}_0(2t) + \hat{Y}_1(2t) \right),$$

since the Fourier transform of an even (odd) function is a cosine (sine) transform. By the Paley-Wiener Theorem, the integral terms vanish for $|t| \geq b$, and (2.6) becomes (2.1). $\square$

3. Partition of the Lorentz quantities. We show next that under the same compact support assumption on $\psi_0$, each term $\oint \left( x_m \alpha_j \partial_j \psi \right) (\text{fixed } j)$ in the Lorentz quantity

$$B_m = \oint \left( x_m \sum_j \alpha_j \partial_j \psi \right) + t \oint \left( \partial_m \psi \right)$$

is eventually a constant-coefficient linear function of $t$, with coefficients depending only on $\psi_0$.

**Theorem 3.1.** If $\psi$ solves (1.1) and $\psi_0$ is supported in $\{r \leq b\}$, then for $|t| \geq b$,

$$\oint \left( x_m \alpha_j \partial_j \psi_t \psi_t \right) = \oint \left( x_m \sum_k \alpha_k \partial_k \psi_0 \cdot \frac{\partial^2}{\Delta} \psi_0 \right)$$

$$-t \oint \left( \partial_m \psi_0 \cdot \frac{\partial^2}{\Delta} \psi_0 \right) + \sum_k \oint \left( \alpha_j \alpha_m \partial_k \psi_0 \cdot \frac{\partial_j \partial_k}{\Delta} \psi_0 \right). \quad (3.1)$$
Proof. Proceeding as in the proof of Theorem 2.1, we get

\[ \mathcal{W} \left( \langle x_m \alpha_j \partial_m \psi_t, \psi_t \rangle \right) = -\mathcal{W} \left( \langle \partial_m (\alpha_j \xi_j \hat{\psi}_t), \hat{\psi}_t \rangle \right) \\
= -\mathcal{W} \left( \langle \alpha_j \xi_j \partial_m \hat{\psi}_t, \hat{\psi}_t \rangle \right), \]

since \( \langle \alpha_j \hat{\psi}, \hat{\psi} \rangle \) is real. Now

\[ \partial_m \hat{\psi}_t = \left( \partial_m \hat{\psi}_0 + \frac{t}{i} \sum_k \alpha_k \theta_k \partial_m \hat{\psi}_0 \right) \cos \rho t \\
+ \left\{ -t\theta_m \hat{\psi}_0 + \frac{1}{i} \sum_k \alpha_k \theta_k \partial_m \hat{\psi}_0 + \frac{1}{i} \alpha_m \frac{\hat{\psi}_0}{\rho} - \frac{1}{i} \sum_k \alpha_k \theta_k \partial_m \hat{\psi}_0 \rho \right\} \sin \rho t. \tag{3.2} \]

Using the double angle identities (2.5), we get

\[ -\mathcal{W} \left( \langle \alpha_j \xi_j \partial_m \psi_t, \hat{\psi}_t \rangle \right) = \frac{1}{2} (X_0 + X_2) + \frac{1}{4} (X_0 - X_2) \cos 2\rho t + \frac{1}{2} X_1 \sin 2\rho t, \tag{3.3} \]

where (after some simplification of \( X_0 \) and \( X_2 \))

\[ X_0 = -\mathcal{W} \left( \langle \alpha_j \xi_j \partial_m \hat{\psi}_0, \hat{\psi}_0 \rangle \right) - \mathcal{W} \left( \frac{t}{i} \left( \langle \xi_m \hat{\psi}_0, \theta_j^2 \hat{\psi}_0 \rangle \right) \right), \]

\[ X_1 = -\mathcal{W} \left( \langle \alpha_j \xi_j \left( \partial_m \hat{\psi}_0 + \frac{t}{i} \sum_k \alpha_k \theta_k \partial_m \hat{\psi}_0 \right), \frac{1}{i} \sum_q \alpha_q \theta_q \hat{\psi}_0 \right) \]

\[ -\mathcal{W} \left( \langle \alpha_j \theta_j \left( -t \xi_m \hat{\psi}_0 + \frac{1}{i} \sum_k \alpha_k \xi_k \partial_m \hat{\psi}_0 + \frac{1}{i} \alpha_m \hat{\psi}_0 - \frac{1}{i} \sum_k \alpha_k \theta_k \partial_m \hat{\psi}_0 \right), \hat{\psi}_0 \rangle \right), \]

\[ X_2 = \mathcal{W} \left( \langle \alpha_j \xi_j \partial_m \hat{\psi}_0, \hat{\psi}_0 \rangle \right) - 2 \mathcal{W} \left( \sum_k \alpha_k \xi_k \partial_m \hat{\psi}_0, \theta_j^2 \hat{\psi}_0 \right) \]

\[ + \sum_k \mathcal{W} \left( \langle \alpha_k \alpha_k \alpha_m \hat{\psi}_0, \theta_j \theta_k \hat{\psi}_0 \rangle \right) - \mathcal{W} \left( \frac{t}{i} \left( \langle \xi_m \hat{\psi}_0, \theta_j^2 \hat{\psi}_0 \rangle \right) \right). \]

Integrating (3.3) in \( \xi \), the method of Section 2 works perfectly to show that the integrals involving the trigonometric functions vanish for \(|t| \geq b\). (\( \partial_m \hat{\psi}_0 = (ix_m \hat{\psi}_0) \) has an entire extension with the same properties as that of \( \hat{\psi}_0 \).) The other integrals simplify to

\[ -\mathcal{W} \left( \left( \sum_k \alpha_k \partial_m (\xi_k \hat{\psi}_0), \theta_j^2 \hat{\psi}_0 \right) \right) - \mathcal{W} \left( \frac{t}{i} \left( \langle \xi_m \hat{\psi}_0, \theta_j^2 \hat{\psi}_0 \rangle \right) \right) \]

\[ + \frac{1}{2} \sum_k \mathcal{W} \left( \left( \alpha_k \alpha_k \alpha_m \hat{\psi}_0, \theta_j \theta_k \hat{\psi}_0 \right) \right). \]

Applying the Plancherel Theorem, we get (3.1). □

Thus \( B_m(\psi) \) is eventually partitioned into \( n + 1 \) linear functions of \( t \), the coefficients of which may be calculated from the Cauchy datum \( \psi_0 \).
Remark 3.2. The interpretation of (3.1) in terms of constants of motion of the solution $R_j \psi$ is not so clear-cut as for the energy. (3.1) implies that
\[ g \left( \langle x_m \alpha_j \partial_j \psi_t, \psi_t \rangle \right) = B_m(R_j \psi) - tP_m(R_j \psi) + \frac{1}{2} \sum_k g \left( \langle \alpha_j \alpha_k \alpha_m \psi_0, \frac{\partial \partial_k}{\Delta} \psi_0 \rangle \right), \quad |t| \geq b. \]

It appears that the coefficients of this linear function of $t$, though constant, cannot be expressed entirely as constants of motion of Riesz transforms of $\psi$.

4. Partition of the zeroth inversional quantity. The zeroth inversional quantity may be written
\[ I_0 = g \left( \left\langle x \sum_j \alpha_j \partial_j \psi, x \psi \right\rangle \right) + t^2 E + 2tg \left( \langle x \cdot \nabla \psi, \psi \rangle \right) \]

Here $x \psi$, for example, is to be thought of as a "vector of spinors" $(x_1 \psi, \ldots, x_n \psi)$, and $x \cdot \nabla \psi$ denotes $\Sigma_k x_k \partial_k \psi$. We would like to show that each $g \left( \langle x \alpha_j \partial_j \psi, x \psi \rangle \right)$ (fixed $j$) is eventually a constant-coefficient quadratic polynomial in $t$.

**Theorem 4.1.** If $\psi$ solves (1.1) and $\psi_0$ is supported in $\{r \leq b\}$, then for $|t| \geq b$,
\[ g \left( \langle x \alpha_j \partial_j \psi_t, x \psi_t \rangle \right) = g \left( \left\langle x \sum_k \alpha_k \partial_k \psi_0, x \frac{\partial^2}{\Delta} \psi_0 \right\rangle \right) + t^2 g \left( \left\langle \sum_k \alpha_k \partial_k \psi_0, \frac{\partial^2}{\Delta} \psi_0 \right\rangle \right) - 2tg \left( \left\langle x \cdot \nabla \psi_0, \frac{\partial^2}{\Delta} \psi_0 \right\rangle \right) + \sum_k \sum_m g \left( \left\langle x_m \alpha_j \alpha_k \alpha_m \psi_0, \frac{\partial \partial_k}{\Delta} \psi_0 \right\rangle \right). \] (4.1)

**Proof.** Since $(\alpha_j \psi, x \psi)$ is real, we have
\[ g \left( \langle x \alpha_j \partial_j \psi, x \psi \rangle \right) = g \left( \langle \alpha_j \partial_j \psi, x \psi \rangle \right) = g \left( \left\langle \alpha_j \xi, \nabla \hat{\psi}, \nabla \hat{\psi} \right\rangle \right), \]
where the gradient is in the $\xi$ variables. Rewriting (3.2) in vector notation, we get
\[ \nabla \psi_t = \left\{ \nabla \hat{\psi}_0 + \frac{t}{i} \sum_k \alpha_k \theta_k \theta \hat{\psi}_0 \right\} \cos \rho t + \left\{ -t \hat{\psi}_0 + \frac{1}{i} \sum_k \alpha_k \theta_k \nabla \hat{\psi}_0 + \frac{1}{i} \sum_k \alpha_k e_k \frac{\hat{\psi}_0}{\rho} - \frac{1}{i} \sum_k \alpha_k \theta_k \theta \frac{\hat{\psi}_0}{\rho} \right\} \sin \rho t, \]
where $e_k$ is the $k$th standard basis vector in $\mathbb{R}^n$. 

In analogy with Secs. 2 and 3, we write

\[ g \left( \frac{1}{i} \left( \alpha_\xi \nabla \psi_0, \nabla \psi_0 \right) \right) = \frac{1}{2} (X_0 + X_2) + \frac{1}{2} (X_0 - X_2) \cos 2\rho t \]
\[ + \frac{1}{2} X_1 \sin 2\rho t, \quad (4.2) \]

where (after a very tedious calculation to simplify \( X_2 \))

\[ X_0 = g \left( \frac{1}{i} \left( \alpha_\xi \nabla \psi_0, \nabla \psi_0 \right) \right) \]
\[ + t^2 g \left( - \frac{1}{i} \left( \alpha_j \xi_j \psi_0, \psi_0 \right) + \frac{2}{i} \left( \sum_k \alpha_k \xi_k \psi_0, \theta \psi_0 \right) \right) \]
\[ + 2t^2 g \left( - \left( \alpha_j \sum_k \alpha_k \xi_j \cdot \nabla \psi_0, \psi_0 \right) + 2 \left( \xi \cdot \nabla \psi_0, \theta^2 \psi_0 \right) \right) \]

\[ X_2 = g \left( - \frac{1}{i} \left( \alpha_j \xi_j \nabla \psi_0, \nabla \psi_0 \right) + \frac{2}{i} \sum_k \left( \alpha_k \nabla (\xi_k \psi_0), \nabla (\theta^2 \psi_0) \right) \right) \]
\[ + \frac{2}{i} \sum_{k,m} \left( \alpha_j \alpha_k \partial_m \psi_0, \theta \psi_0 \right) \]
\[ - \frac{1}{i} \sum_k \left( \left( \alpha_j \theta \psi_0, \partial_k \psi_0 \right) + \left( \partial_k (\alpha_j \theta \psi_0), \psi_0 \right) \right) \]
\[ - \frac{1}{i} \sum_k \left( \left( \alpha_k \psi_0, \partial_k (\theta^2 \psi_0) \right) + \left( \partial_k (\alpha_k \psi_0), \theta^2 \psi_0 \right) \right) \]
\[ + t^2 g \left( \frac{1}{i} \left( \alpha_j \xi_j \psi_0, \psi_0 \right) \right) + 2t^2 g \left( \alpha_j \sum_k \alpha_k \xi_j \cdot \nabla \psi_0, \psi_0 \right) \].

In deriving the expression for \( X_2 \), we have repeatedly used the formula

\[ \partial_k \theta_m = (\delta_{km} - \theta_k \theta_m) / \rho. \quad (4.3) \]

The proof that the integrals

\[ \int_{\mathbb{R}^n} (X_0 - X_2) \cos 2\rho t \, d\xi, \quad \int_{\mathbb{R}^n} X_1 \sin 2\rho t \, d\xi \quad (4.4) \]

vanish for \( |t| \gg b \) now goes through as in Secs. 2 and 3, with one slight modification. Because of (4.3), the extensions to complex \( \rho \) of functions like \( \partial_k (\alpha_j \theta \psi_0) \), and thus the extension of \( X_2 (\cdot, \theta) \), may have simple poles at \( \rho = 0 \). To get around this, we note that for fixed \( \theta \), \( Z = \rho^2 X_2 \) is entire, of exponential type \( 2b \), and of Schwartz class in real \( \rho \). Furthermore, \( Z(-\rho, -\theta) = Z(\rho, \theta) \). Since \( n \geq 3 \), \( \rho^{n-3} \int_{S^{n-1}} Z \, d\theta \) is entire, of exponential type \( 2b \), of class \( L^1 \) in real \( \rho \), and even. Thus the integrals (4.4) vanish for \( |t| \gg b \).
By (4.2), then, the eventual value of $g((1/i)\langle \alpha, \xi, \nabla \phi, \nabla \phi \rangle)$ is

$$\frac{1}{2} \int_{\mathbb{R}^n} (X_0 + X_2) \, d\xi = g\left\{ \frac{1}{i} \left( \sum_k \alpha_k \nabla (\xi_k \psi_0), \nabla (\theta^2 \psi_0) \right) \right\}$$

$$+ \frac{t^2}{i} \left( \sum_k \alpha_k \xi_k \psi_0, \theta^2 \psi_0 \right) + 2t \left( \nabla \cdot (\xi \psi_0), \theta^2 \psi_0 \right)$$

$$+ \frac{1}{i} \sum_k \sum_m \left( \alpha_j \alpha_k \alpha_m \partial_m \hat{\psi}_0, \theta \psi_0 \right)$$

$$- \frac{1}{i} \sum_k \left( \alpha_j \theta \psi_0, \partial_k \psi_0 \right) - \frac{1}{i} \sum_k \left( \partial_k (\alpha_j \theta \psi_0), \psi_0 \right)$$

$$- \frac{1}{i} \sum_k \left( \alpha_j \psi_0, \partial_k (\theta^2 \psi_0) \right) - \frac{1}{i} \sum_k \left( \partial_k (\alpha_k \psi_0), \theta^2 \psi_0 \right) \right\} \quad (4.5)$$

By the skew-adjointness of $\partial_k$, the last four terms above sum to 0. ($\theta / \psi_0$ is in the $L^2$ Sobolev class $H^{(n-1)/2} \subseteq H^1$, since each differentiation introduces one new factor of $\rho^{-1}$.) Applying the Plancherel Theorem to (4.5) without these terms, we get exactly (4.1). □

Formula (4.1), the energy partition result, and the identity

$$i_0 = (r^2 - t^2) + 2th$$

show that $I_0$ is eventually partitioned into $2n + 1$ constant-coefficient quadratic or linear functions of $t$.

5. Remarks.

(a) The energy partition result trivially gives a partition result for the dilational quantity $H$, since $h = t \varepsilon + \sum x_k p_k$. The result on partition of the Lorentz quantities gives a partition result for the $m$th inversional quantity $I_m$, since

$$i_m = -2t b_m - 2x_m \sum k x_k p_k + (r^2 + t^2) p_m + \sum_k g \langle x_k \alpha_m \psi, \alpha_k \psi \rangle.$$  

$H$ is partitioned into $n + 1$ linear functions,

$$t g \left( \alpha, \partial_\psi, \psi \right) = t E(R, \psi), \quad |t| \geq b;$$

$$\sum_k g \langle x_j \partial_\psi, \psi \rangle = H(\psi) - t E(\psi), \quad \text{all } t.$$  

$I_m$ is partitioned into $n + 3$ quadratic functions, $n + 1$ of them making up the $-2t B_m(\psi)$ term, using Theorem 3.1; and the other two being $t^2 P_m(\psi)$ and $I_m(\psi) - t^2 P_m(\psi) + 2t B_m(\psi)$.

(b) It is natural to ask whether the present approach gives new information about solutions of the wave equation $\ddot{u} = \Delta u$. (Again we assume odd space dimension $n \geq 3$.)
Let $v = \dot{u}$. Conserved quantities of interest are \[ E(u) = \frac{1}{2}||v||^2 + \frac{1}{2}||\nabla u||^2 \quad \text{(energy)}, \]
\[ P_m(u) = \langle \langle \partial_m u, v \rangle \rangle \quad \text{(momenta)}, \]
\[ B_m(u) = \frac{1}{2}\langle \langle x_m v, v \rangle \rangle + \frac{1}{2}\langle \langle x_m \nabla u, \nabla u \rangle \rangle + tP_m(u) \quad \text{(Lorentz quantities)}, \]
\[ H(u) = tE(u) + \langle \langle x \cdot \nabla u, v \rangle \rangle + \frac{n-1}{2} \langle \langle u, v \rangle \rangle \quad \text{(dilational quantity)}, \]
\[ I_0(u) = \frac{1}{2}||rv||^2 + \frac{1}{2}||r\nabla u||^2 + t^2E(u) \]
\[ + 2t\langle \langle x \cdot \nabla u, v \rangle \rangle - \frac{n-1}{2}||u||^2 \]
\[ + (n-1)t\langle \langle u, v \rangle \rangle \quad \text{(zeroth inversional quantity)}. \]

We would first like to know whether the constituents $\frac{1}{2}||\partial_j u||^2$ of the potential energy eventually take on constant values, assuming compact support for $u_0$ and $v_0$. The answer is yes, as we can see formally, without doing the Paley-Wiener calculation, by applying energy equipartition to the wave equation solution $R_j u$. This solution has potential energy $\frac{1}{2}\nabla(\partial_j/\sqrt{-\Delta})u||^2 = \frac{1}{2}||\partial_j u||^2$, which should eventually equal $\frac{1}{2}E(R_j u)$. In fact, this approach can be made rigorous, even though the Cauchy data for $R_j u$ are not, in general, supported in $\{r < b\}$ when $u_0$ and $v_0$ are. What matters is that the extensions of $\partial_j u_0$ and $\partial_j v_0$ to complex $\rho$ have the correct exponential type, and that their inner products have the correct total parity in $\rho$ and $\theta$. We have

**Theorem 5.1.** If $u$ is a solution of the wave equation with $u_0$ and $v_0$ supported in $\{r \leq b\}$, then

$$\frac{1}{2}||\partial_j u||^2 = \frac{1}{2}E(R_j u), \quad |t| \geq b.$$  

Of course, one could also prove Theorem 5.1 (and Theorems 5.2 and 5.3 below) by applying Duffin's original method.

For the Lorentz quantities, the partition theorem analogous to energy equipartition was given by the author in [1]:

$$\frac{1}{2} \langle \langle x_m \nabla u, \nabla u \rangle \rangle = \frac{1}{2}B_m(u) - \frac{1}{2}tP_m(u), \quad |t| \geq b.$$  

Just as for the energy, we can extend the eventual partition argument for $B_m$ to cover the non-compactly supported $R_j u$. This, along with a short calculation in the $\xi$ domain (recall (4.3)) which shows

$$\langle \langle x_m \partial_j u, \partial_j u \rangle \rangle = \langle \langle x_m \nabla (R_j u), \nabla (R_j u) \rangle \rangle,$$

gives

**Theorem 5.2.** If $u$ is a solution of the wave equation with $u_0$ and $v_0$ supported in $\{r \leq b\}$, then

$$\frac{1}{2} \langle \langle x_m \partial_j u, \partial_j u \rangle \rangle = \frac{1}{2}B_m(R_j u) - \frac{1}{2}tP_m(R_j u), \quad |t| \geq b.$$
The situation for the inversionsal quantity $I_0$ is similar. By a result of Zachmanoglou [9], $||u||^2$ is constant for $|t| \geq b$ if $u_0$ and $v_0$ are supported in $\{r \leq b\}$, say

$$||u||^2 = C(u), \quad |t| \geq b.$$  

This result can also be extended to Riesz transforms of solutions with Cauchy data in $\{r \leq b\}$. The partition result for $I_0$, proved by the author in [1], says that

$$\frac{1}{2} \||r\nabla u||^2 = \frac{1}{2} t^2 E(u) - tH(u) + \frac{1}{2} I_0(u) + \frac{n-1}{2} C(u), \quad |t| \geq b.$$  

A calculation in the $\xi$ domain using (4.3) gives

$$\frac{1}{2} \||r\partial_\xi u||^2 = \frac{1}{2} \||r\nabla (R Ju)||^2 - \frac{n-1}{2} \||R Ju||^2.$$  

Since the $I_0$ partition result can be extended to $R Ju$, we have

**Theorem 5.3.** If $u$ is a solution of the wave equation with $u_0$ and $v_0$ supported in $\{r \leq b\}$, then

$$\frac{1}{2} \||r\partial_\xi u||^2 = \frac{1}{2} t^2 E(R Ju) - tH(R Ju) + \frac{1}{2} I_0(R Ju), \quad |t| \geq b.$$  

(c) For the Maxwell equations, one can apply the results of Remark b to a vector potential (see [2, Remark 3.2]) to get new partition results. It seems, however, that these new formulas must involve the vector potential explicitly, and cannot be written in terms of the electromagnetic field alone.

(d) The above finite time partition results (for both the wave and Dirac equations), true for solutions with compactly supported Cauchy data, can be extended to asymptotic results for Cauchy data with suitable spatial decay. Essentially, one applies the Riemann-Lebesgue Lemma in place of the Paley-Wiener Theorem (see, e.g., [4]).

(e) The energy partition result of Sec. 2 is quite different from the equipartition result given by Costa and Strauss [3]. Their result concerns the conserved quantity $||\psi||^2$. They show that if a choice of $\alpha$-matrices is made with

$$\alpha_j = \begin{pmatrix} 0 & \sigma_j \\ \sigma_j & 0 \end{pmatrix},$$

where the $\sigma_j$ are $N/2 \times N/2$ matrices satisfying

$$\sigma_j \sigma_k + \sigma_k \sigma_j = 2 \delta_{jk}, \quad \sigma_j^* = \sigma_j,$$

then eventually,

$$||\psi_1||^2 + \cdots + ||\psi_{N/2}||^2 = ||\psi_{N/2+1}||^2 + \cdots + ||\psi_N||^2.$$  

Formally, this is wave equation energy equipartition for the potential

$$(-\Delta)^{-1/2}(\psi_1, \ldots, \psi_{N/2}).$$

**Acknowledgements.** The author would like to thank R. Glassey for supplying him with a list of conserved quantities for Dirac’s equation, and E. Zachmanoglou for introducing him to the general subject of references [1, 2] and the present paper.
